A representative from URS maintained a log of conditions observed in the test pits, visually classified the soils encountered according to the Unified Soil Classification System and obtained representative bulk samples at selected intervals. The test pits were backfilled with excavated materials and compacted using the bucket of the backhoe. The stratigraphic contacts indicated within the test pit logs represent the approximate boundaries between soil and rock types; actual transitions may be more gradual and indistinct. The subsurface conditions depicted are only for the specific locations reported, and therefore, are not necessarily representative of other locations. The sample intervals are shown on the test pit logs attached in Appendix A.

2.1.2 Dynamic Cone Penetration Test

Roadway subgrade testing was conducted using the Dynamic Cone Penetrometer (DCP). A total of 30 DCP tests were performed for the proposed site access roads to depths of between 1 and 3 feet bgs. The DCP is a widely used device to determine in situ strength properties of base materials and subgrade soils. The four main components of the DCP include the cone, rod, anvil, and hammer. The cone is attached to one end of the DCP rod while the anvil and hammer are attached to the other end. Energy is applied to the cone tip through the rod by dropping the 17.64-lb hammer a distance of 22.6-inches against the anvil. The diameter of the cone is 0.1575-inch larger that the rod to ensure that only tip resistance is measured. The number of blows required to advance the cone into the subsurface materials is recorded. The DCP index is the ratio of the depth of penetration to the number of blows of the hammer. This can then be correlated to a variety of material properties, including California Bearing Ratio (CBR) and
Resilient Modulus, both of which are used in pavement design. Logs of the DCP test results are included in Appendix C to this report. Approximate DCP test locations are shown on Figure 2.

2.1.3 Field Soil Electrical Resistivity Testing

Resistivity tests for the proposed Wind Energy Project site were performed on September 24, 2007 to assess the electrical resistivity of the near surface soil. The locations of the tests are noted on Figure 2, Site Plan. Test locations were selected to correspond with the sites of the proposed Wind Turbine Generators. A Strata-Scout Model R-40CY resistivity meter was used to measure the resistance by the 4-point (Wenner) configuration at equal spacing of 5, 10, and 20 feet for tests R-1 through R-5. A Nilsson Model 400 meter was used in the same configuration at equal spacing of 5, 15, and 20 feet for tests R-1 through R-5. The resistance and spacing were used to calculate the resistivity at each location. Results of the resistivity tests are presented in Appendix B. These indicators can be used for determinations regarding corrosion potential and grounding grid design.

2.2 LABORATORY TESTING

Upon completion of the field investigation, samples obtained from test pits were transported to our Portland, Oregon laboratory for further examination and testing. The laboratory tests included the following:

- Visual soil classification performed in general accordance with ASTM D 2487;
- Moisture content performed in general accordance with D 2216;
- Grain size analysis performed in general accordance with ASTM D 422 and D 1140;
- Atterberg Limits in general accordance with ASTM D4318..

Complete individual laboratory test results are shown in Appendix B of this report.
3 SITE DESCRIPTION

3.1 REGIONAL GEOLOGY

The White Salmon, Washington area is located within the Cascade Range and the Columbia Intermontane Physiographic Province. The project area is located just within the western boundary of the Columbia Plateau, which is located at the western edge of the Columbia Intermontane Physiographic Province (Freeman et al, 1945). This lowland province is surrounded on all sides by mountain ranges and highlands, and covers a vast area of eastern Washington and parts of northeastern Oregon and western Idaho. The Columbia Plateau is underlain by a series of layered basalt flows extruded from vents (located mainly in southeastern Washington and northeastern Oregon) during the Miocene epoch (between 5.3 and 23.8 million years before present [B.P.]). Collectively, these basalt flows are known as the Columbia River Basalt Group (CRBG). Individual basalt flows range in thickness from a few millimeters to as much as 300 feet. Where significant time elapsed between successive flows, interflow zones developed. The interflow zones are characterized by the presence of highly weathered basalt and paleosols. These interflow zones are generally significantly weaker than the surrounding basalt and sometimes form basal failure surfaces for large landslide complexes within the CRBG.

A variety of younger volcanic rocks and sedimentary materials that range from Pliocene (1.8 to 5.3 million years B.P.) to Holocene (less than 10,000 years B.P. in age) overlie the CRBG in the project area. Sedimentary rocks are generally thought to underlie the basalts in the Project area.

3.2 SITE GEOLOGY

The proposed Project site is located within the northern boundary of the structural Hood River Valley, which extends a few miles into southern Washington. In general, the geology of the area consists of basalt flows extruded from local vents, layered with conglomerate, tuff, tuff breccias, and other volcanoclastic deposits. These formations are typically overlain by silt and clay soil of varying thickness in the Project vicinity.

The bedrock underlying the proposed Project site consists of Grande Ronde Basalt of the CRBG and Quaternary basalt of Underwood Mountain - a shield volcano that lies approximately midway between the lower reaches of the Little White Salmon and White Salmon Rivers. Its southern slopes drain to the Columbia River. Site geology is presented on Figure 3.

Underwood Mountain Basalt Unit: The Pleistocene-epoch (1.8 million years to 10,000 years B.P.) basalts and cinders erupted from the Underwood Mountain vents and overlie the Tertiary
CRBG Grande Ronde and Wanapum basalts. Public records of wells located within the Underwood volcanic field indicate a 310-foot thick repetitive sequence of thin lava flows (2 to 8 feet thick), cinders and silty-clays overlying a productive confined aquifer consisting of intensely fractured Grande Ronde basalt (Yinger, 2000 and 2001). The Miocene-epoch Grand Ronde Basalt consists of multiple basalt flows that are a subgroup of the CRBG, and has been described to have a thickness of up to 1000 feet, although the thickness in the Project vicinity is not known.

Field observations of rock outcrop and test pits excavated during a geotechnical investigation at the proposed site indicate that the near-surface rock consists of yellow-gray volcanioclastic rocks, medium to dark gray, fine-grained to medium-grained basalt and andesite, which is fractured into angular gravels, cobbles, and boulders. The basalt observed in the test pits was most commonly vesicular, very soft to moderately hard, and decomposed to slightly weathered. Some zones displayed non-vesicular characteristics and were generally harder. In most exposures the basalt was moderately to highly weathered, with fractures and vesicles filled by clayey residual soil. In most of the test pits excavated in this basalt, the rock is weathered into varying layers of residual (clay) soil, and clayey gravelly cobble-sized basalt. The residual soil layers often exhibit remnant rock structure.

**Unconsolidated Deposits:** Unconsolidated deposits are thin to absent in the Project vicinity. Based on observations made during field reconnaissance, the surficial materials consisted primarily of a thin veneer of brown, silty topsoil that is likely derived from forest duff and wind-blown deposits. The thickness of this material varied across the site from a few inches to three feet, based on test pit observations. In several areas bedrock and talus were observed at the ground surface.

**Landslide Deposits:** Regional Geologic maps indicate the presence of Quaternary-age mass wasting landslide deposits located to the north of Underwood Mountain (Korosec, 1987, excerpted in Figure 3, this report). These deposits are mapped as a large landslide, estimated to be approximately 1/3 square mile in area and almost a mile long. A URS Engineering Geologist reviewed stereo aerial photographs that were flown specifically for this project in 2007 and performed a one day site reconnaissance. There is no obvious evidence, based on the review, to suggest the presence of a landslide as mapped on the 1:100,000 scale geologic map. If landslide deposits are present, they are so old that most or all of the geomorphic evidence has been removed by erosion. A separate Landslide Hazard Report for the project is presented as Appendix C to this report.

**Faults:** No faults are mapped within the footprint of the proposed Project area. However, faults are mapped approximately 1.5 miles southwest and northeast of the proposed Project area. Many
of these faults are inferred and shown as dotted lines buried by younger surficial deposits. The activity of the area faults is unknown. However, a review of aerial photography shows no indication of recent movement along the trace of the inferred faults.

3.3 SUBSURFACE CONDITIONS

The following is a general summary of the soil conditions encountered in the explorations conducted at the site to date. More detailed description of the soils encountered in the test pits are provided on the logs included in Appendix A.

Based on the current test pits and field observations, we anticipate that unconsolidated soils extend up to 3 feet below ground surface (bgs). The surficial soils are primarily characterized as soft, moist sandy SILT [ML] to CLAY with sand [CL], and clayey SAND [SC]. Immediately beneath the unconsolidated soils, rock with variable strength and weathering properties is present. The test pit data is limited to depths no greater than 16 feet bgs. It is anticipated that rock quality of the basalts will improve with depth but that weaker interflow zones consisting of volcaniclastic material and paleosols are possible at any depth. Prior to final design of the tower foundations, additional subsurface investigations (boreholes) will be required to provide geotechnical data at foundation and anchor depths.

The United States Department of Agriculture National Resources Conservation Service (NRCS) describes the soils in the project vicinity as follows (USDA, 2003):

- **Chemawa Series**: The Chemawa series consists of very deep soils (up to 5 feet) formed in alluvium from volcanic ash and basalt. The soils exist on terraces, footslopes and backslopes at elevations between 800 and 2500 feet in southeast Skamania County and southwest Klickitat County. Chemawa Soils are well drained with slow to medium runoff and moderate permeability.

- **McElroy Series**: The McElroy series consists of very deep soils (up to 5 feet) formed in colluvium and residuum from basalt with a mantle of volcanic ash that influences soils in the top 9 to 13 inches. The soils exist on the footslopes and backslopes of mountains on slopes from 5 to 90 percent at elevations from 400 to 2600 feet in eastern Skamania County and western Klickitat County. McElroy Soils are well drained with medium to rapid runoff and moderate permeability. The series was established in 1981 following the introduction of volcanic ash from the eruption of Mt. St. Helens.

- **Timberhead Series**: The Timberhead series consists of very deep soils (up to 5 feet) formed in residuum and colluvium from basalt mixed with volcanic ash. The soils exist on mountain slopes between 5 and 65 percent at elevations from 2000 to 3600 feet in Skamania County and western Klickitat County. McElroy Soils are well drained with medium to rapid runoff and moderate
permeability. The series was established in 1981 following the introduction of volcanic ash from the eruption of Mt. St. Helens.

- **Underwood Series:** The Underwood series consists of very deep soils (5 feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between 2 and 50 percent at elevations between 500 and 2700 feet in southeast Skamania County and west Klickitat County. Chemawa Soils are well drained with slow to medium runoff and moderately slow permeability.

- **Undusk Series:** The Undusk series consists of very deep soils (5 feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between 2 and 50 percent at elevations between 500 and 2700 feet in southeast Skamania County and west Klickitat County. Chemawa Soils are well drained with slow to medium runoff and moderately slow permeability.

### 3.4 GEOLOGIC HAZARDS

#### 3.4.1 Description of Geologic Hazards

In general, geologic hazards are geologic processes or geological conditions that constitute a threat to human safety, improved property, and the natural environment. For the purposes of this report, the focus is on geologic hazards associated with the construction and operation of the proposed wind energy project. The primary geologic hazards present in the project area can be divided into three categories: landslides, seismic, and volcanic. Landslide hazards include rotational-translational slides, earthflows, debris slides, and debris flows. Seismic hazards can include ground shaking, fault surface rupture, settlement, liquefaction, and lateral spreading. Volcanic hazards at the project site are generally limited to ash fall from any of three nearby Cascade volcanoes. By identifying areas prone to specific geologic hazards, design and construction details can be modified to avoid dangers to human safety, improved property, and environmentally sensitive areas from such hazards as a result of project construction and operation.

#### 3.4.2 Landslide Hazards

The most common types of landslides in the Pacific Northwest include rock falls, topples, rotational-translational slides, earthflows, debris slides, and debris flows. Most slope failures are complex combinations of these distinct types, but the generalized groupings enable the investigator to communicate the types of hazards anticipated and observed.
Landslides can be initiated in marginally stable slopes by a number of natural and human disturbances. Processes and conditions that can trigger slope failure include earthquake shaking, volcanic eruption, deforestation, intense rainfall, and rapid snowmelt. Two of the most common triggering events in southern Washington are intense precipitation and human alterations.

The Pacific Northwest is subject to severe rainfall storm events, particularly in the wet winter and spring months of November through April. These relatively high-precipitation storm events can trigger slope failures through a number of mechanisms. Water infiltration into zones of weakness can trigger failures by reducing the frictional resistance to sliding, increasing pore pressures within slope masses and adding weight acting downslope. Typically, all three mechanisms combine during longer duration, heavy precipitation or rain on snow events to trigger slope stability problems.

Landslide hazards were assessed as part of the public document review, aerial photograph investigation, and field reconnaissance. Results of the landslide hazard review are presented as a separate technical report in Appendix D to this report.

### 3.4.3 Seismic Hazards

Liquefaction is a phenomenon whereby soils undergo significant loss of strength and stiffness when they are subjected to vibration or large cyclic ground motions produced by earthquakes. Typically, cyclic loading of saturated soils leads to the build up of excess pore-water pressure as a result of soil particles being rearranged with a tendency toward denser packing. Under undrained conditions (such as during earthquake shaking), loads are transferred from the soil skeleton to the pore-water with consequent reduction in the soils’ shear strength.

Saturated granular soils without cohesive fines (i.e. gravels, sands and silts) are most susceptible to liquefaction. Other factors affecting the potential for liquefaction in soils are density, amplitude of loading, confining pressure, past stress history, age of soil deposit, the size, shape and gradation of particles, and the soil fabric structure. Liquefaction-induced ground settlement and lateral spreading have been the primary cause for extensive damage to aboveground structures, foundations and pipelines during many earthquakes.

Test pits excavated at the project site encountered shallow bedrock covered with a combination of cohesive and cohesionless soil. No groundwater was observed in any of the test pits. Based on the soils encountered during the field explorations, it is URS’ opinion that the potential for liquefaction is very low at this site.

The risk of seismically induced settlement and lateral spreading is low due to the low
liquefaction potential. It is UR5’ opinion settlements and lateral spread induced by a seismic event will be minimal.

Coseismic surface rupture occurs when a fault breaks to the land surface during an earthquake. Surface rupture is usually associated with moderate to large earthquakes (magnitude 6.5 or greater) or, rarely during smaller, very shallow events. There are no mapped faults crossing the site. Therefore, the potential for coseismic primary surface rupture at the proposed project site is small.

3.4.4 Volcanic Hazards

Within the region of the site, the USGS recognizes three volcanoes as either active or potentially active: Mount Hood, Mount Adams, and Mount St. Helens. In the last 200 years, only Mount St. Helens has erupted more than once (USGS, 2002b). Impacts in the geographic region surrounding the Project site from volcanic activity can be either direct or indirect. Direct impacts include the effects of lava flows, blast, ash fall, and avalanches of volcanic products. Indirect effects include mudflows, flooding, and sedimentation. Data accumulated as a result of the 1980 Mount St. Helens eruption indicate that there could be ash fallout in the geographic region surrounding the Project site if one of the three regional volcanoes were to erupt.

In the event that a volcanic eruption would damage or impact Project facilities, the Project facilities would be shut down until safe operating conditions return. If an eruption occurred during construction, a temporary shut-down would most likely be required to protect human health and equipment.

3.5 GROUNDWATER CONDITIONS

During the current subsurface exploration groundwater was not encountered in the site up to a depth of 16 feet bgs. It should be noted that these observations reflect groundwater levels at the time of the field investigation and actual groundwater levels may fluctuate significantly in response to seasonal effects, regional rainfall, and other factors not observed during this investigation. There may be regional or perched water tables at greater depth. Prior to final design of the tower foundations, additional subsurface investigations (boreholes) will be required to provide geotechnical data at foundation and anchor depths. Future deep foundation investigations will include observation of groundwater, if encountered.
4 SEISMIC DESIGN

4.1 REGIONAL SEISMICITY

The Pacific Northwest has four types of seismic sources due to the presence of the Cascadia subduction zone. These sources include (1) the subduction zone megathrust, which represents the boundary (interface) between the subducting Juan de Fuca plate and the overriding North American plate; (2) faults located within the Juan de Fuca plate (referred to as the intraplate or intraslab region); (3) crustal faults principally in the North American plate; and (4) volcanic sources beneath the Cascade Range (Wong and Silva, 1998). Each of these events has different causes, and therefore produces earthquakes with different characteristics (that is, peak ground accelerations, response spectra, and duration of strong shaking).

Because of their proximity, crustal faults are possibly the most significant seismic sources to inland sites. Studies by Pezzopane (1993) and Geomatrix Consultants (1995) show that at least 70 crustal faults having earthquake potential exist in southwest Washington and northwest Oregon. Many of these faults were unknown or not recognized as being seismogenic a decade ago. Although the largest known crustal earthquake in south-west Washington and western Oregon is only about $M_W$ 6 (Wong and Bott, 1995), potential exists for events of $M_W$ 6½ or greater along several recognized faults.

4.2 2006 IBC SEISMIC DESIGN

We recommend that all structures on the site be built in accordance with the seismic design provisions presented in the 2006 version of the IBC, and ASCE/SEI 07-05. At this time, and without unconfined compressive strengths of the bedrock, URS best describes these soils as Soft Rock (Soil Site Class B). Based on the site location and site conditions described above, we recommend that the values listed in Table 4-1 be used for seismic design of the project in accordance with Section 1613.5.3 of the 2006 IBC. The occupancy category of the proposed structure is assumed III as per Section 1613.5.6 of the 2006 IBC.

5 CONCLUSIONS AND RECOMMENDATIONS

5.1 GENERAL

In support of this report, URS has conducted a limited site investigation, including several test pits, to determine the near-surface properties of the soil and rock. Rock, with varying strength and weathering characteristics, was encountered at shallow depths (ranging between 3 to 12 feet bgs). Because of the presence of relatively shallow rock, and the high potential overturning loads anticipated for the turbine towers, URS recommends rock anchored mat-slab foundations to support the turbines for this preliminary assessment (see Figure 4). However, a drilled shaft foundation concept may prove to be more beneficial in the future, as the design advances. The viability of this foundation concept will be determined with the final geotechnical engineering report for this site.

5.2 WIND TURBINE GENERATOR FOUNDATIONS

As of the date of this report, the tower designer and tower locations have not been finalized. Because of this, the exact loads on the foundations required to support the turbines is not known. One proposed turbine construction contractor, D.H. Blattner & Sons, Inc. has preliminarily assumed installation of 80-meter high GE 1.5 Wind Turbine Generators (WTG) which will be supported by 30 foot-deep concrete foundations. Each turbine tower will be coupled to the foundation with 128 anchor bolts (consistent with GE towers). Based on the soil conditions present at the site, URS preliminarily recommends that mat-slab foundations be used to support the proposed wind turbine tower structures. Once the final exploration is completed, URS may also recommend that the foundation system be drilled shafts.

Due to the anticipated high axial and lateral loads exerted by the towers, URS recommends that the base of the foundation excavation be established in competent rock and be properly leveled to provide uniformity of support. Following excavation, the bearing surfaces should be thoroughly cleaned of loosened or disturbed rock, by hand if necessary. This removed rock should be A URS inspector should manually probe the area within the excavation bottom for confirmation of the bearing surface and to identify any soft areas. Any soft or unsuitable rock encountered at the base of foundation excavations should be removed. URS anticipates that the excavation base would irregular, but if completed properly, the allowable bearing capacity on the excavated base would be on the order of 30,000 psf with an allowable increase of 1/3 to this value for temporary loading conditions. This would have to be verified with additional borings and laboratory testing of the cored rock.
5.2.1 Settlement of WTG Foundation

The WTG foundations are anticipated to be established in rock. Because of this, elastic settlement of the foundation is anticipated to occur as the loads are applied, however, once the tower is constructed, additional settlements would be negligible.

5.2.2 Earth Pressure and Friction Factors

Passive earth pressures acting against the toe of the shallow foundations and friction on the base of the foundations may be considered to provide resistance to lateral forces tending to cause translational sliding. These structural members should be considered for counteracting lateral forces only if the member is placed in direct contact with tested and approved soils. If the foundation is constructed by using forms, lean concrete may be placed between the foundation and the undisturbed wall of the adjacent excavation in order to provide the direct contact required to consider passive pressure for counteracting lateral movement. The lean concrete should have a minimum 28-day compressive strength of 1,500 psi. An allowable passive pressure of 8,000 psf may be used for the underlying bedrock, for the foundation face located more than one-foot below the adjacent elevation of the bedrock. This is based on a factor of safety of two and requires confirmation with the final design.

An ultimate friction factor of 0.5 for mass concrete on the compacted granular fill can be used for design for those portions of the foundations with full positive pressure on the base of the foundation. Only long-term dead loads should be considered in calculating the available friction on the foundation base.

5.2.3 Rock Anchor Design and Installation

We anticipate that rock anchors are used in the final foundation designs to resist overturning loads and provide lateral stability, we recommend nominally prestressed anchors consisting of high-strength reinforcing bars grouted into the rock using polyester resin grout such as Fasloc or Celtite. These commercially available, two-component grouts are contained in plastic cartridges. The grout cartridges are placed in the hole and the bar is driven into the hole while being rotated in order to expose and mix the grout. The use of the concrete grout is an acceptable alternative, but will generally require longer anchors and a larger diameter drilled anchor hole for a given bar diameter. Due to the possible fractured and vesicular nature (presence of small voids within the rock mass) of the basalt (the extent of which needs to be determined with a final geotechnical report), the concrete grout alternative may be necessary to prevent reduction of anchor strength due to loss of resin grout into voids. Prior to final design of the tower foundations, additional
subsurface investigations (boreholes) will be required to provide geotechnical data at foundation and anchor depths. Core samples from the borehole investigations will provide information on the prevalence of voids in the rock mass, which will allow URS to develop recommendations for rock anchor construction.

5.2.3.1 Rock Anchor Capacity

The load bearing capacity of each anchor depends on the “fixed anchor length” (L), the spacing of the anchors, and engineering properties of the grout and rock. For this project, we anticipate that rock anchors will be generally be used singly, or in single rows, where anchor spacing is greater than 0.25L. If anchor spacing is greater than 0.25L or consisting of multiple rows, we should be contacted to evaluate the effects of a single anchor capacity. Preliminary anchor design charts have been prepared (See Figures 5 and 6) to assist in the selection of anchor length to achieve a designed anchor capacity. The charts have been prepared based upon an analysis of the possible failure mode of the anchors, including the following:

- Bond failure between bar and grout;
- Bond failure between grout and rock;
- Pullout of inverted cone of rock surrounding the anchored tendon;
- Tensile yield of the tendon.

Based upon the properties of the rock and grout, and if the anchors meet the spacing and the distance requirements specified above, failure at the grout/rock interface will control the allowable anchor capacity up to 60% of the bar yield strength. Anchors used to resist lateral movements should not be placed at an angle shallower than 45 degrees to the surface.

Figure 5 presents anchor design of polyester resin grout with unconfined compressive strength of approximately 13,000 psi. Figure 6 presents alternative anchor design curve if 15,000-psi compressive strength concrete grout is used instead of the resin grout. The concrete grout may be placed by gravity flow prior to inserting the steel bar. Each bar should be fitted with centralizers that center the bar in the hole.

Holes may be drilled using an air track or similar rotary percussion device. Hole diameters should be at least ½-inches greater than the bar thread diameter if concrete grout is used. All holes must be thoroughly cleaned of debris prior to placement of the anchor.

In order to attain the higher anchor capacities required for the project, we recommend the use of steel alloy anchor bars with an ultimate tensile strength of 150 kips per square inch (ksi)
conforming to ASTM standard A-722. Threaded and deformed bars of this type are available from DYWIDAG Systems International, Inc. The anchor should be nominally prestressed to approximately 10 percent of the design load to take up slack in the system and provide an appropriately stiff anchorage. A portion of this prestress will bleed off due to creep and to downward deformation of the foundation when the dead and live loads are applied. A sufficient residual prestress is expected to remain to ensure that excessive anchor system deformation during uplift does not occur before full uplift resistance is mobilized. Direct-pull hydraulic jacks or a torque wrench may be used to apply prestress. Following prestressing, the free anchor length may be grouted with low-strength concrete to protect against corrosion. Overall, based on the resistivity determinations, the site is not corrosive.

5.2.3.2 Rock Anchor Testing

It is important that each anchor performs satisfactorily, therefore, we recommend that each anchor be tested using either performance testing or proof testing criteria. At a minimum, the ten percent of the at each site should be performance tested. Following satisfactory completion of performance testing, we recommend that each remaining rock anchor be proof tested. Proof testing evaluates the as-built anchor capacity. Performances and proof testing should be completed by incrementally loading the anchors in accordance with the schedule below. At each increment, the movement of the anchor should be recorded to the nearest of 0.001 inch with reference to an independently fixed anchor point. The jack load should be monitored with a properly calibrated pressure gauge or load cell. The test load sequences presented in Table 5-1 should be employed.

Each load should be held at each increment just long enough to obtain the movement reading, but not more than one minute. The testing should not exceed the 80% of the bar yield strength. The 1.33P test load should be held for 10 minutes. Total movements should be recorded at 1, 2, 3, 4, 5, 6, and 10 minutes.

Performance and proof test acceptance criteria should be developed in conjunction with URS when details of the anchor design and materials are known. A URS representative should monitor all rock anchorage installation and testing to determine whether the rock layer has been sufficiently penetrated and to monitor the proof and performance tests.

### 5.3 RETAINING WALLS

Following are typical design parameters for wall types that we believe represent the range of systems that may be constructed at this site. Walls may be required to provide a level working pad at the tower pads or for the embankment modifications. Please contact us if any additional design values or wall types need to be addressed.

#### 5.3.1 Retaining Wall Design Parameters

Lateral soil pressures on a retaining wall depend on several factors including retained soil type, wall fixity, drainage provisions and the influence of surface loads imposed behind the wall. We have provided typical design parameters for wall types that we believe represent the range of retaining wall systems that are likely to be constructed at this site. Our recommendations are based on the following assumptions:

- Retaining walls will be designed to restrain both existing soils and constructed fills.
- Retaining walls will be backfilled with free draining crushed rock, in accordance with Section 5.3.3 (Retaining Wall backfill) of this report.
- Adequate subsurface drainage will be provided.

### 5.3.2 Equivalent Fluid Densities (Soil)

Unrestrained walls have no fixity at the top and are free to rotate about their base through tilting or translation. Most cantilever retaining walls fall into this category (unless they are attached to buildings or other structures). A lateral movement of 0.005 times the height of the retaining wall may be required to achieve this active pressure. For these walls, we recommend that a lateral equivalent fluid density of 40 pcf be used for design. If the retaining walls are used to restrain sloping backfill, URS should be contacted for additional designs.

Restained walls are rigid structures where essentially no relative movement occurs between the structure and the soil. Most basement walls and other rigid walls that are restrained by buildings, parking decks, floor slabs or other perpendicular walls fall into the category of restrained walls. For restrained walls, we recommend that a lateral equivalent fluid density of 60 pcf be used for design. If the retaining walls are used to restrain sloping backfill, URS should be contacted for additional designs.

### 5.3.3 Retaining Wall Backfill

Backfill within 3 feet of retaining walls should consist of free draining crushed rock, free of organics and debris. This material should meet the requirements of the 2006 WSDOT Standard Specifications for Road, Bridge and Municipal Construction, Section 9-03.14(1). Backfill beyond 3 feet from the wall should meet requirements described in Section 5.6.5 (Structural Fill Material). We recommend that all fill be compacted to 95% of the maximum dry density as determined by the Modified Proctor test (ASTM 1557). Additionally, we recommend that any backfill that is placed within 5 feet of the wall (measured horizontally) be compacted with lightweight, hand operated compaction equipment. Over-compaction of this fill can increase wall pressures.

We recommend the placement of a 4-inch diameter slotted PVC pipe wrapped in non-woven geotextile fabric at the base of the wall backfill to facilitate drainage of this area depending on the final elevation of the basement slab. These pipes should be drained to a collection point and sumped.
5.4 TOWER FOUNDATION EXCAVATION

5.4.1 Temporary Shoring

It is the responsibility of the contractor to deal with the temporary construction excavation and site safety including overseeing the means, methods, and sequencing of construction operations. URS does not assume any responsibility for the contractor's activities or construction site safety for the information provided in this section. In this site the rock layer is relatively at shallow depth (3 feet to 10 feet bgs) and there is sufficient space left for providing the adequate slope as per OSHA requirement for the basement excavations, and hence, the temporary shoring is not recommended. URS does anticipate, however, that the rock will be able to be constructed with a near vertical face, possibly using shallow anchor bolts and gunite to seal its surface. This will be determined with the final construction.

5.4.2 Dewatering

During the excavation of test pits at the site, no ground water was encountered up to a depth of 16 feet bgs. Hence it is anticipated that seepage of ground water will not be a problem within foundation excavation at the site. Presence of groundwater will be determined during subsequent geotechnical investigations to be performed in support of final foundation design.

5.4.3 Rock Excavation

It should be anticipated that hard rock will be encountered during excavation work. Machinery capable of removing these this large intact rock, such as heavy duty backhoes with rock ripping teeth, hydraulic thumbs or pneumatic rock breaking equipment, should be anticipated for this work. There is also a possibility that the rock will have to be blasted, pre-split or utilize expansive materials prior to excavation, depending on the final depth of excavation. The actual methods will be developed with final design.

5.5 SHALLOW FOUNDATIONS (ANCILLIARY STRUCTURES)

We understand that new footings may be utilized to support ancillary structures such as the transformer pads. For footings that bear on shallow, undisturbed native soils, we recommend a net allowable bearing pressure of 2,500 pounds per square foot (psf). This bearing capacity is based on a settlement limit of 0.5 inches.

Allowable bearing pressures may be increased by one-third when considering load cases that include transient loads such as wind and seismic forces. We recommend that a unit weight of 115 pcf be used to calculate the reduction of overburden pressure due to excavation. Backfill
soils will be slightly heavier than excavated soils but not enough to significantly influence the bearing pressure.

Exterior footings could be turned down footings from the slab and should be founded at least 18 inches beneath the lowest exterior grade to provide frost protection. Continuous wall footings should have a minimum width of 18 inches and isolated column footing should have a minimum plan dimension of 24 inches.

For foundations designed and constructed as specified in this report, we estimate settlements on the order of 0.5-inches. We anticipate the majority of the settlement will occur during construction, essentially as the loads are applied. The remainder of the settlement will likely occur within three weeks following the application of the load.

### 5.5.1 Passive Loads and Friction Factor

Passive earth pressures acting on the sides of shallow foundations and friction on the base of the foundations may be considered to provide resistance to lateral forces tending to cause translational sliding. These structural members should be considered for counteracting lateral forces only if the member is placed in direct contact with tested and approved soils. If the foundation is constructed by using forms, lean concrete may be placed between the footing and the undisturbed soil of the adjacent excavation in order to provide the direct contact required to consider passive pressure for counteracting lateral movement. The lean concrete should have a minimum 28-day compressive strength of at least 1,500 psi. An allowable passive pressure having an equivalent fluid pressure of 250 pcf may be used for design. This is based on a factor of safety of two.

An ultimate friction factor of 0.3 for mass concrete on compacted tested and approved native subgrade can be used for design for those portions of the foundations with full positive pressure on the base of the foundation. Only long-term dead loads should be considered in calculating the available friction on the foundation base.

### 5.5.2 Slabs on Grade

The subgrade under all floor slab areas should be prepared in accordance with Section 5.5.1. We recommend that floor slabs be underlain by a granular base course at least 6-inch thick to provide uniformity of support and to act as a capillary break against moisture migration through the slab. The granular base course should consist of well-graded gravel or crushed rock with a maximum nominal size of ¾ inch and having less than 5 percent by weight passing the No. 200 sieve. The base course should be compacted to at least 95 percent of its maximum dry density as measured.
by the modified Proctor test (ASTM Standard D 1557). We recommend a modulus of subgrade reaction of 200 pounds per cubic inch (pci) for the base course.

Even with a capillary break as outlined above, there is the possibility of some floor moisture or dampness. If floor moisture is a critical consideration due to storage of materials directly on the floor slab, or because of the use of glued-down impervious floor coverings such as tile or linoleum, we recommend the use of an under-slab impermeable membrane placed directly below the slab. To maximize water tightness, the membrane must be installed in accordance with the manufacturer’s recommendations.

5.6 CONSTRUCTION CONSiderATIONS

5.6.1 Site Work Preparation

Prior to construction of any new foundations, all areas that will receive fill, base rock, or structures should be stripped of all surface vegetation, organic topsoil, and any deleterious materials that might be encountered. Any soft or unsuitable soils encountered during stripping or excavation should be removed and replaced with structural fill meeting the requirements described in Section 5.6.4 (Wet Weather Earthwork). All subgrades should be approved by the Engineer prior to the placement of any materials or foundation elements.

5.6.2 Shallow Foundation Excavation

We recommend that excavations for foundations in soil and weathered rock be accomplished with a straight-edged grading bucket to minimize disturbance of the bearing surfaces. Following excavation, the bearing surfaces should be thoroughly cleaned of loosened or disturbed soil, by hand if necessary. Any soft or unsuitable soils encountered at the base of foundation excavations should be removed and replaced with compacted structural fill meeting the requirements described in Section 5.6.4 (Wet Weather Earthwork).

5.6.3 Dry Weather Earthwork

After areas are stripped or excavated to design elevations, we recommend scarification of the resulting subgrade in all areas that will receive fill or structures to a depth of 8 inches. The scarified soil should be compacted to at least 95% of its maximum dry density as determined by the standard proctor test, ASTM D698.
5.6.4 Wet Weather Earthwork

We anticipate that the native soils found at the site will be sensitive to moisture and erosion. Therefore, during or after wet weather, it may be necessary to import granular materials for structural fill to protect open subgrade materials. It may also be necessary to install a granular working pad to support construction equipment. Delays in site earthwork activities should be anticipated during periods of heavy rainfall. Additionally, site clearing and stripping activities may expose subgrade material that may be damaged if subjected to disturbance from construction traffic. During wet weather, we recommend that site stripping and excavation be performed using an excavator with a straight-edged bucket that does not traverse the final subgrade.

When a granular working base is used to protect open subgrade material and construction equipment, the base should consist of a suitable thickness of crushed rock or ballast placed by end-dumping off an advancing pad of rock fill. Because construction practices can greatly affect the amount of rock required, we recommend that if conditions require the installation of a granular working blanket, the design, installation, and maintenance be made the responsibility of the contractor. After installation, the working blanket should be compacted with a minimum of 4 passes with a smooth-drum roller.

We recommend that the contractor minimize soil exposure during the rainy season by proper timing of grading and construction activities and be prepared to shut down all earthwork if heavy precipitation occurs. We recommend that water runoff be diverted from foundations and equipment pads, and that all runoff water be directed to proper drainage areas and not be allowed to pond.

5.6.5 Structural Fill Material

We recommend that all fills intended to support structures be placed in horizontal lifts not exceeding about 8 inches in loose thickness and be compacted to at least 95 percent of the maximum dry density as determined by the Modified Proctor method (ASTM D 1557), unless where specified above.

Imported structural fill should be clean, well-graded granular material, free of organics and debris and meeting the requirements of the 2006 WSDOT Standard Specifications for Road, Bridge and Municipal Construction, Section 9-03.14(1). The procedure to achieve proper density of a compacted fill depends on the size and type of compacting equipment, the number of passes, thickness of the layer being compacted, and certain soil properties. When the size of the
excavation restricts the use of heavy equipment, smaller equipment can be used, and the soil must be placed in lifts thin enough to achieve the required compaction. We recommend that methods of compaction be left to the discretion of the contractor, with compaction testing provided by URS.

We do not recommend the use of on-site soils for structural fill. This material may be used for miscellaneous fill and landscaping applications provided these areas are not intended to support structures. On-site soils should be compacted to at least 95% of the maximum dry density as determined by the standard proctor test, ASTM D698.

5.6.6 Embankment Design

Once the required roadway improvements on the SDS property are determined for the construction traffic equipment, URS could develop a formal embankment design that will have a static Factor of Safety (FOS) of 1.3. URS anticipates the majority of embankments will be relatively small and constructed over level ground. URS envisions that the general embankment section will consist of two zones and have finished slopes of 2H:1V. The final designs for the embankments will come with the final geotechnical engineering report.

5.6.7 Temporary Slopes

Depending on the Contractor’s proposed excavation and shoring plan, temporary cut slopes or shoring may be required during construction. If open cuts are utilized, maximum slope inclinations must be made in accordance with regulations established by OSHA. In accordance with OSHA, the sands and silty sand overburden soils encountered on site are classified as Type C. The maximum allowable temporary slope for Type C soils is 1½ horizontal to 1 vertical (1½H: 1V) if fully dewatered. Flatter slopes will be required if dewatering provisions are not considered for the site. The slopes should be inspected and maintained as required by OSHA. For the excavations into the underlying bedrock, URS will provide site specific designs from the borings to be advanced for the final report.
6 CONSTRUCTION QUALITY ASSURANCE

We recommend that URS be retained to provide construction monitoring and testing services during foundation construction. The purpose of our field monitoring services is to confirm that site conditions are as anticipated, to provide field recommendations as required based on conditions encountered, and to document the activities of the contractor to assess compliance with the project recommendations provided by URS. We also recommend that URS review and comment on the foundation plans. The purpose of this review would be to identify any potential problem areas and to provide cost saving or efficiency improving suggestions, if possible.
7 LIMITATIONS

This report presents recommendations pertaining to the proposed structures as represented to URS, as described herein. The findings and recommendations presented in this report are based upon soil conditions observed the available subsurface explorations, interpolation of the soil conditions between test pits, and extrapolation of these conditions throughout the proposed site area. They are further based on the assumption that the subsurface conditions do not deviate appreciably from those reported and those assumed. However, the possibility of different conditions cannot be discounted.

In the event that changes in design loads or structural characteristics described in this report are made, URS should be retained to review our design recommendations and their applicability to the revised design plans. In this way, any required supplemental recommendations can be made in a timely manner.

This report has been prepared for the specific project, purpose, and client stated in the report; the report may not be adequate for other uses. The use of the recommendations of this report for other projects or purposes or by other parties is not authorized.

Although URS has endeavored to characterize the surface and subsurface conditions at the site, URS is not as able to assess potential construction difficulties as is a contractor specializing in the work to be performed. Consequently, the Contractor is responsible, and URS is not, for final evaluation of potential construction difficulties.

This report has been prepared in accordance with the care and skill generally exercised at the present time by reputable professionals in the field of geotechnical engineering, under similar circumstances, for projects in the project locality. No other warranty, either expressed or implied, is made as to the professional advice presented herein.

- **BEDROCK**, yellow-brown to gray mottled, tuffaceous, decomposed to highly weathered, pumice, rock fragments in dark orange soil, very small vesicles

  - **Becomes gray or salt and peppered, black staining on fracture surfaces, highly weathered, very soft**

  - **Becomes gray with orange-white specks, highly to moderately weathered, soft, spheroidal weathering patterns observed, large rounded boulders observed (~2.5 feet diameter)**

APPENDIX B
FIELD SOIL RESISTIVITY AND LABORATORY TESTING
Resistivity tests for the proposed Wind Energy Project site were performed on September 24, 2007 to assess the resistivity of the near surface soil. Table B-1 presents the results of these measurements. The soil resistivity at locations R-1, R-2, R-3, and R-5 are shown graphically in Figure B-1. Soil resistivity at location R-4 is shown in Figure B-2.

Saddleback Wind Energy Project
White Salmon, Washington
33758687

PARTICLE SIZE DISTRIBUTION CURVES
APPENDIX C
PAVEMENT ENGINEERING
**Anticipated Haul Route**

URS observed the anticipated haul route from the SDS Lumber facility to the Saddleback site during a site visit in September, 2007. We anticipate the route to run along SR 14 to Cook-Underwood Road, up Cook-Underwood Road to Kollock-Knapp Road, up Kollock-Knapp Road to a sharp right hand turn onto Sciggins Road, and then a left onto the logging road on SDS property (CG-2930) to the Saddleback site.

**Anticipated Haul Routes**

Very little information is available about the existing pavement and base thicknesses along the haul route. From observations made while driving along the haul route, the pavements appear to be generally in good condition however, we understand that the pavements along Cook-Underwood Road had been recently improved with a chip seal and/or minor overlay. Some areas of the Kollock-Knapp Road showed signs of distress.

Construction for the proposed project is not anticipated to start for about three years. Therefore, three years of local traffic will traverse the pavement prior to the initiation of construction traffic. URS recommends that just prior to the initiation of construction for the project a comprehensive pavement assessment program be undertaken to establish the condition of the existing pavements. This would then be coupled with a mechanistic-empirical approach for establishment of remaining pavement life just prior to construction traffic. Once this is done, the potential effects of construction traffic on the pavements current state could be captured. For the proposed project URS recommends a comprehensive investigation of the existing pavements including: a visual pavement condition survey; Falling Weight Deflectometer testing; pavement coring; laboratory testing; and Dynamic Cone Penetrometer testing. This program will give a baseline metric for the pavement, base and subgrade conditions prior to the construction traffic.

No information was available at the time of this report regarding the existing average daily traffic (ADT) volumes along the proposed haul route. This information will be necessary during the analysis portion of the work, just prior to the construction traffic. If this information is not readily available, a traffic survey should be performed to determine the ADT and type of vehicle traffic along the proposed haul route. This information will be used to determine the remaining life of the existing pavement section and the pavement section that will be required post construction.
Truck Hauling Information

In order to mobilize the sections of wind tower equipment to the site, it is anticipated that they will arrive on rail to the SDS Lumber facility, be off loaded onto specialized trucks, and then transported up hill to the Saddleback site. URS understands that they could possibly arrive by barge also, but this is to be determined. The final vendor for the wind towers has not been selected at the time of this report. URS has made some general assumptions regarding typical tower configuration for the purpose of this report. URS understands that at the time of this report, the towers will be about 250 feet in height, with blades that are approximately 135 feet in length. We assume that each wind tower consist of the tower section, hub, blades and a nacelle. Heavy and oversized pieces, such as the tower sections and blades will be trucked to the site individually, while other components will be bundled together for transport from SDS Lumber.

Tubular towers are typically transported in 60 to 90-foot long sections that weight from 42 to 59 tons. Three rotor blades are required for each tower and are about 135 feet in length and about 7 tons each. The entire rotor assembly weighs approximately 35 tons. The nacelle is approximately 30 feet long, 12 feet wide by 12 feet high and weighs approximately 57 tons. Specialized trucking equipment is required to transport the tower pieces from SDS Lumber to the Saddleback site. Truck size and axle loading depends on the piece of equipment being transported and any anticipated restrictions that will be encountered along the haul route such as low overhead conditions, uneven traveling surfaces and load restrictions. URS anticipates that approximately 8-10 truck hauls will be required for each tower installed. Therefore, more than 500 heavy haul trips will be required over the county roads for the towers only, in addition to construction equipment. This quantity does not include delivery of construction materials such as concrete required for the foundation, grading equipment to construct roads and prepare the site or other construction traffic associated with neighborhood construction and deliveries.

URS is able to obtain information from Anderson Trucking Services, Inc. (ATS), who specialize in wind turbine transportation, on typical axle loading information for the 80-meter high, GE 1.5 Wind Turbine Generators. URS will include this information in our final report.

Strategy and Design Parameters for Haul Roads On SDS Property

URS drove and observed the haul roads on SDS property during our September, 2007 site visit. The existing logging road (CG-2930) to the Saddleback site has primarily been used for accessing stands of timber for harvesting and exporting timber from the site. The dirt road is currently surfaced with soil and rock and is in poor condition. In its current state the road is not suitable for the trucks that will be carrying the wind tower equipment.
URS will analyze the existing topography and work within the equipment limitations of the haul trucks that will be transporting the equipment to the site. Likely this will include rebuilding large sections of the existing road and surfacing with rock. For areas with steep slopes, we anticipate flattening and rebuilding the slopes and placing asphalt in select areas to allow access by the hauling equipment. The asphalt could remain in place or be removed at the end of the project. URS will develop design parameters for the pavement suitable to protect the section through construction.

**Strategy and Design Parameters for Haul Roads On SDS Property**

URS drove and observed the haul roads on SDS property during our September, 2007 site visit. The existing logging road (CG-2930) to the Saddleback site has primarily been used for accessing stands of timber for harvesting and exporting timber from the site. The dirt road is currently surfaced with soil and rock and is in poor condition. In its current state the road is not suitable for the trucks that will be carrying the wind tower equipment.

URS will analyze the existing topography and work within the equipment limitations of the haul trucks that will be transporting the equipment to the site. Likely this will include rebuilding large sections of the existing road and surfacing with rock. For areas with steep slopes, we anticipate flattening and rebuilding the slopes and placing asphalt in select areas to allow access by the hauling equipment. The asphalt could remain in place or be removed at the end of the project. URS will develop design parameters for the pavement suitable to protect the section through construction.

**Pre and Post Heavy Haul Strategy for Pavement Assessments**

URS will implement a thorough investigation program to capture the existing pavement, aggregate base and subgrade conditions along the alignment prior to heavy hauls. This program will consist of the following:

- A visual pavement condition survey and report of the surface of the existing pavements along the haul route to quantify weak or deteriorated areas that may need repair
- Pavement core holes to obtain the pavement thicknesses along the haul route
- Sampling of the near surface soils for classification
- Laboratory testing, as necessary, of the soils to further refine their classification and strength parameters
• Dynamic Cone Penetrometer (DCP) testing in selected locations where pavement widening may need to occur to determine the strength of the near surface subgrade soils

• Falling Weight Deflectometer (FWD) testing along the haul route to assess the *insitu* strength of the asphalt, aggregate base and subgrade soils

URS will use the results of this investigation to determine the capacity of the existing pavement section and what, if any, modification to the pavement section may be required to support the heavy haul trucks. URS concern is that the heavy loading may significantly deteriorate the existing pavement section, which was likely not designed for such heavy loads. URS will provide design recommendations for improving the pavement section, as necessary, prior to the beginning of the hauling program.

Design parameters critical to this analysis include determining the number of equivalent single axle loads (ESALs), which are based on trailer loading, number of axles and their configuration, and the thickness and resilient modulus of the subgrade, aggregate base and pavement materials. These factors combined with recommended values for initial serviceability, standard deviation, reliability, and a terminal serviceability as outlined by the American Association of State Highway and Transportation Officials (AASHTO) make up the main components of this analysis. Using these values, URS will determine minimum acceptable asphalt and aggregate base thicknesses to support the proposed loading.

At the completion of the hauling program and construction, URS proposes to perform a visual assessment of the surface conditions of the pavement, similar to what was performed before the construction began. The visual assessment will identify weak or deteriorated areas along the haul route which may require mitigation. Depending on the outcome of the preconstruction pavement analysis and the visual observation of post construction conditions, URS may prepare a mitigation design to repair the pavements to pre-construction conditions or better. 20 years is the typical pavement design life.

DCP TEST DATA

Project: Saddleback Windfarm
Location: White Salmon, WA

Date: 9/24/2007
Project No.: 33758687
Start: D feet bgs

Hammer:
- 10.1 lbs.
- 12.6 lbs.
- Both hammers used

Sol Type:
- CH
- CL
- All other soils

Bearing Capacity based on correlations of CBR and Bearing values (Design of Concrete Airport Pavement, Portland Cement Association, page 8, 1959)
APPENDIX D
LANDSLIDE HAZARDS
Pursuant to Skamania County Code, Title 21A, Chapter 21A.06 - Landslide Hazard Areas, URS has conducted a preliminary landslide hazard evaluation of the proposed Saddleback Wind Energy (SWE) project wind turbine site. The project location is shown on Figure C-1.

**Landslide Hazard Report Methodology**

A URS Licensed Engineering Geologist conducted a site specific landslide hazard investigation. The investigation consisted of:

- Review of Sections of the County Code that address Geologically Hazardous Areas;
- Review of existing available topographic, geologic and soils literature and maps;
- Analysis of project-specific stereo aerial photographs;
- Review of project test pit logs and soil samples;
- A one day site reconnaissance.

According to the County Code, the primary criteria for landslide hazard designations are: presence of pre-existing, known mappable landslides; slope angle; and/or composition of the near-surface soils or rock.

URS has created a color-coded map of the study area using an existing USGS 10 meter digital terrain model (DTM) to segregate slopes into three categories: slopes less than 20%; slopes between 20% and 30%; and slopes greater than 30%. We then superimposed the United States Department of Agriculture, National Resources Conservation Services (NRCS) soil survey map onto the slope map to provide soil type information. The resulting Landslide Hazard Map is presented herein as Figure C-1.

**Landslide Hazard Area Delineation**

Skamania County recognizes three classes of landslide hazard areas (LHAs). Class I (Severe) LHAs are considered to present a severe landslide hazard and are distinguished as areas of known mappable landslide deposits which have been designated landslide hazard areas by the local legislative body. Class II (High) LHAs are areas with slopes between twenty and thirty percent that are underlain by soils that consist largely of silt, clay or bedrock, and all areas with
slopes greater than thirty percent. Class III (Moderate) LHAs are areas with slopes between twenty percent and thirty percent not included in Class II.

URS reviewed available geologic and soils literature to develop a landslide hazard classification for the proposed SWE project. An existing published regional geologic map (partially recreated in Figure 3 of the main text of this report) indicates a large landslide in the northeast corner of the study area underlying Tower Line ‘C’. Review of stereo photographs of the area where the landslide deposits are mapped, coupled with a site reconnaissance, indicate that there is little geomorphic evidence for landslide activity such as obvious scarps, hummocky or bench terrain, lobate toe areas, or redirected watercourses. No deep subsurface investigations have been carried out at the site to date, but future explorations in support of design for the turbine tower foundations will provide subsurface information that will provide information regarding the presence, or lack of, landslide deposits in the area. Based on our preliminary investigation, there does not appear to be any area of the site that meets Skamania County’s criteria for a (Class I) LHA.

Class II LHAs are shown in red on Figure C-1. The Class II LHAs at the site are predominantly associated with the steep slopes to the west of proposed Tower Lines ‘A’ and ‘B’. There are also steep slopes to the east of the 7 southernmost ‘A’ Line towers, and on both sides of Tower Line ‘C’.

Although none of the proposed turbines are located within Class II LHAs, several of the towers along the western side of the project site (Tower Lines ‘A’ and ‘B’) are located along ridgelines with descending slopes that are locally greater than 35 degrees (70%). The heads of some of the drainages along these slopes are arcuate indicating possible mass-wasting activity such as landslides, debris flows, and/or earthflows.

Based on aerial photo and field observations, the primary mass wasting process below the ridgelines appears to be debris flows and soil creep. No evidence for deep-seated, block failure type landslides was observed. Local surficial creep of near-surface soils is indicated by the presence of pistol-buttressed trees on some of the slopes, primarily on the descending slope west of the northern portion of Tower Line ‘A’. Other slopes have mature conifer stands that indicated little or no soil creep. Further subsurface investigation in support of final tower foundation design will help determine if there are weak rock or soil layers that could contribute to more deep-seated failure of the ridges and provide information on the quality of the rock mass underlying the ridgelines.

It appears that the primary concern for towers located adjacent to the Class II LHAs is the
potential for headward erosion of the steep drainages by debris or earth flow processes. Erosion rates of these drainages are unknown, but no obvious recent mass wasting features were observed in the aerial photos or during the site reconnaissance.

Class III LHA's have been delineated adjacent to proposed wind turbines along the southern ‘A’ Line, and the ‘C’ Line. Class I LHA's are not anticipated to have any impact on the proposed facilities due to the robust nature of the proposed foundation designs.

Conclusions and Recommendations

URS has conducted a Landslide Hazard Evaluation for the proposed SWE wind farm project in Southeast Skamania County. The evaluation has identified several areas where the proposed wind turbine generators are located adjacent to slopes that meet Skamania County’s criteria for Class II and Class III Landslide Hazard Areas. The primary hazard to the proposed towers appears to be the potential for exposure to headward erosion of steep drainages on the slopes below some of the tower locations. Exposure of the towers to headward erosion of the steep slope drainages can be minimized by providing maximum possible setbacks from the tops of the steep slopes and / or by siting the turbines along portions of the ridgelines that are above intervening spur ridges. The most critical area of exposure to Class II LHA's is the narrow ridge at the southern portion of the ‘A’ Line.

It is URS's opinion that the proposed SWE facilities can be constructed and operated without danger to human life or the surrounding environment due to landslide hazards.

Criteria and Methodology

The vegetation study area includes the area of a proposed substation, turbine strings, and their associated access roads, and existing secondary roads proposed for improvement. Vegetation was surveyed in a 300-ft corridor centered on proposed turbine strings and their associated access roads, in 50-foot corridors adjacent to existing roads proposed for improvement in conjunctions with this project, and in 25 additional acres in three locations proposed for staging areas and location of a substation (Figure 1).

Numerous vegetation classification systems are available for characterizing the plant communities across a landscape. The classification system used for this analysis was USDA Forest Service classification system (Brown 1985). It was selected for: (1) ability to address the variety of vegetation conditions in the study area; and (2) ability to interpret their function as wildlife habitat.

The aerial photographs are DNR orthophotos taken in January 2002 and were scaled to 1:600, and a maximum 3-foot resolution.

The available color photo coverage was overlain with the project base map, and vegetation types within the study area were digitally mapped using scanned color aerial photographs and ER Mapper 6.3 software by Earth Resources. Photographic signatures were calibrated using field observations. Final maps of the approximate vegetation type boundaries were adjusted using field survey observations, field notes, field maps, and oblique photos. Areas

The USDI Fish and Wildlife Service (USFWS), and the Washington Natural Heritage Information System (WNHIS) were consulted for information on the existence of special status plant species and important habitats that would support special status species in the project vicinity.

Special status plant species are native species that have been accorded special legal or management protection because of concern for their continued existence. There are several categories of protection, depending on the magnitude of threat to continued existence, and existing knowledge of population levels. Any plant species that is in danger of extinction throughout all or a significant portion of its range is defined as "endangered." A "threatened" species is a species that is likely to become endangered in the foreseeable future. Species of concern are candidates for listing as endangered or threatened.
Insert Figure 1  Study Area
A search of the WNHIS database for records of listed or proposed threatened or endangered plant species was conducted. Records of special status species documented within two miles of the proposed project area were obtained. Also, species records for a large area surrounding the project vicinity were obtained to indicate potentially occurring species that may not been recorded because of a lack of detailed surveys for these species.

**Affected Environment**

**Vegetation Communities**

The project area is located in the Southern Washington Cascades Province (Franklin and Dyrness 1988). This area is characterized by generally accordant ridge crests separated by steep, deeply dissected valleys. The project falls within the *Abies grandis* and *Pseudotsuga menziesii* major vegetation zones (Franklin and Dyrness 1988). Climate is wet and cool, receiving a significant portion of its precipitation in the form of snow which accumulates in winter snowpacks as deep as 1 to 3 meters.

The project area is located specifically on Underwood Mountain northwest of White Salmon, Washington. Major drainages in the area include the White Salmon and the Little White Salmon River basins to the east and west of the site respectively. Both basins drain to the Columbia River south of the site, which drains to the Pacific Ocean.

Historically, the project area was dominated by coniferous species—grand fir (*Abies grandis*), and Douglas-fir (*Pseudotsuga menziesii*). Historical species dominance was dependent on elevation, aspect, underlying soil, and previous disturbance history (Franklin and Dyrness 1988). Mixed conifer and deciduous forest stands usually followed disturbances, but occasionally deciduous-dominated stands developed, depending on the disturbance type and physical environment. Typical deciduous species were alder (*Alnus rubra*, *A. sinuata*), Pacific dogwood (*Cornus nutallii*), and big-leaf maple (*Acer macrophyllum*).

The predominant land use in the surrounding area between Underwood Mountain and the Little White Salmon River is commercial forest production. Some land east of the Little White Salmon is zoned for 2-, 5-, and 10-acre residential use, but the land is currently in commercial timber production and is owned by SDS Lumber Company and Broughton Lumber Company, and the Washington Department of Natural Resources. The rural communities of Mill A and Willard are both located west of the Little White Salmon River. Mill A, the closer of the two communities, is approximately 1.5 miles from the nearest turbine site. Willard is approximately 2.25 miles north of the nearest turbine site in the A string.

Current vegetation conditions are heavily influenced by forest management activities over the last century. Land in the project area is privately owned, managed industrial forest. While forest management has not reduced tree species diversity, it has resulted in a shift in species dominance to the commercially valuable Douglas-fir and in changes to stand structure and complexity, patch size, and species distribution. Average stand age probably declined from relatively short stand rotation ages. Few large, old conifer trees occur in the project area and there are no known late-successional or “old-growth” stands within or adjacent to the project area, though small groups of big trees occur.
Common understory plants include sword fern (*Polystichum munitum*), vanilla leaf (*Achlys triphylla*), false Solomon’s seal (*Smilacena racemosa*), western starflower (*Trientalis latifolia*), Columbia windflower (*Anemone deltoidea*), snowberry (*Symphoricarpos albus*), vine maple (*Acer circinatum*), Oregongrape (*Berberis nervosa*), red-flowering currant (*Ribes sanguineum*), and red elderberry (*Sambucus racemosa*). A list of all plant species observed within the project area is found in Table 1.

The vegetation communities within the project area are common within the region and maintained through forest management, and to a lesser extent natural disturbance. Because of private ownership, rugged landscape, and the value of high-volume timber producing land, these vegetation communities are expected to persist within the region during the foreseeable future.

Five vegetation communities and wildlife habitats were identified within the project area:

- Grass-forb Stand (recent clearcuts)
- Brushfield/Shrub Stand
- Conifer-Hardwood Forest
- Conifer Forest
- Riparian - Deciduous

The approximate acreage of each habitat type within the study area by turbine string, road, and other proposed impact areas is shown in Table 2. The locations of the communities are shown in the vegetation community maps (Figure 2). These acreage figures and maps are based on June 2003 conditions. The locations and areas of plant communities will change over time through natural succession, forest development, and forest management.

**GRASS-FORB STAND**

Grass-forb Stands are found in the project vicinity in recently clearcut areas. Grass-forb is the stand condition in the USDA Forest Service classification system defined as areas where shrubs comprise less than 40 percent crown cover and are less than 5 feet tall (Brown, 1985). This stand type occurs when a disturbance such as timber harvest, fires, or wind has killed or removed most or all of the larger trees, or when brush fields are cleared for planting. These units may range from mainly devoid of vegetation to dominance by herbaceous species (grasses and forbs). Tree regeneration in these units is generally less than 5 feet tall and 40 percent crown cover.

In Grass-forb stands within the project vicinity vegetation is minimal and consists predominantly of weedy herbaceous species, including bull thistle (*Cirsium vulgare*), Canada thistle (*Cirsium arvense*), and dandelion (*Taraxacum officinale*). These areas generally consist of ubiquitous coarse woody material (CWM), occasional slash piles, and large areas of bare ground. Within the project’s proposed impact area there are approximately 22.3 acres of grass-forb vegetation community.

Insert Figure 2 Vegetation Community Map
BRUSHFIELD/SHRUB STAND

Brushfields are defined as the shrub stand condition in the USDA Forest Service classification system (Brown 1985). They develop on land following clearcut tree harvesting or other disturbances that remove vegetation. In keeping with Washington Forest Practices Rules, Chapter 222 WAC, all harvest units are planted within 3 years after harvest or a period of from 1 to 10 years as determined by the department in the case of a natural regeneration plan and must maintain minimum stocking levels of 150 vigorous, well-distributed undamaged seedlings per acre of commercial tree species.

Thus the majority of brushfields are actually young plantations (typically Douglas-fir, although many landowners are now planting mixed species) that have not yet reached the closed canopy stage or shaded out the shrub species. The type may have large amounts of bare soil, and often has slash and other logging debris on the ground. Vegetation (other than planted conifers) often consists of remnants from the forest understory and early successional annuals. There are vine maple, Sitka alder, beaked hazelnut (Corylus cornuta), serviceberry (Amelanchier alnifolia), Himalayan blackberry (Rubus discolor), bracken fern (Pteridium aquilinum), sword fern, oceanspray (Holodiscus discolor), fireweed (Epilobium angustifolium), wooly yarrow (Achillea millefollium), serviceberry (Amelanchier alnifolia), Himalayan blackberry (Rubus discolor), bracken fern (Pteridium aquilinum), sword fern, oceanspray (Holodiscus discolor), fireweed (Epilobium angustifolium), wooly yarrow (Achillea millefollium), pearly everlasting (Anaphalis margaritacea) and grasses as ground cover.

Vegetation control has occurred in conjunction with forest management and includes herbicide application, mechanical control, or both. These areas are visually and functionally different from areas where control has not occurred. Despite control efforts, or where they have not occurred, dense shrub thickets frequently occur, dominated by the native vine maple. Within the thickets are small alders and Douglas-fir that occasionally grow taller than the vine maple. These areas also may have patches of alder saplings, salmonberry (Rubus spectabilis), vine maple, red elderberry, oceanspray, lupine (Lupinus sp.), Oregon oxalis, and grass. Small diameter coarse woody material (CWM) is common. Within the project’s proposed impact area there are approximately 45.8 acres of brushfield/shrub vegetation community.

CONIFER-HARDWOOD FOREST

Conifer-Hardwood Forest is found in the project vicinity in the closed sapling-pole stand condition, under the USDA Forest Service vegetation classification system (Brown 1985). The forest canopy in these stands is dominated by a mix of bigleaf maple and Douglas-fir, with some red alder. Canopy height typically ranges from 40 to 60 feet. Canopy closure is between 60 and 80 percent. Maple forms about 30 percent of the canopy cover with Douglas-fir forming most of the rest of the canopy. Stands may have distinct tree canopy layers with deciduous overtopping emerging conifer or remnant conifer over the deciduous component. Stands with shrub layers that merge with the canopy layers are found in the project vicinity. The shrub layer varies from open to dense and contains vine maple, salmonberry, thimbleberry (Rubus parviflora), red elderberry, beaked hazelnut, and Pacific dogwood (Cornus nutallii). The herbaceous layer contains sword fern, trailing blackberry, oxalis, grasses, and moss. Within the project’s proposed impact area there are approximately 147.9 acres of conifer-hardwood vegetation community.
CWM is dependent on stand age, but is typically low to moderate. Deciduous snags outnumber conifer snags, although depending on stand origin, short well decayed conifer snags may be present.

**Conifer Forest**

Coniferous Forest is found in the project area in closed sapling-pole-sawtimber stands and large sawtimber stands. Within the project area and most of the region, Coniferous Forests are dominated by Grand fir and Douglas-fir. The closed sapling-pole-sawtimber is a continuum of tree diameter sizes with saplings being relatively small, poles being in the 8-12 inch range, and sawtimber ranging from 12 to 23 inches. Important to these stand types is the closed canopy and relative short live crowns found in the pole and sawtimber stages. The closed canopy results in the exclusion of most shrub species and many herbs.

CWM in this stage is typically low and consists of remnants from previous stands. Snags are typically rare, although small diameter snags become more frequent in the pole and sawtimber stages as shading and resource competition kills subdominants.

Large sawtimber is considered to be at least 21 inches in DBH. Within-stand differentiation has begun and dominants are beginning to overtop and out-compete other tree species. Competition for space results in more light reaching the forest floor and shrub and herbaceous communities typically become more diverse. CWM and snags are generally rare, although the number of snags and amount of CWM may be variable amount stands, dependent on past harvest practices, stand management, and actual stand age.

These forests are used for commercial forestry, and are generally regenerated after harvest, although some may be the result of natural disturbance combined with commercial planting. They are subject to timber management activities including harvest, replanting, and stand improvement activities. These forests are widespread in the project vicinity. Within the project’s proposed impact area there are approximately 85.8 acres of conifer vegetation community.

**Riparian Deciduous Forest**

Natural and anthropogenic disturbances frequently result in domination by deciduous species in near-stream areas. Within the project area this type occurs in the area identified on the USGS topographic map as “Cedar Swamp.” Historically this area was dominated by very large, old cedar, which have been logged. The area is now dominated by willow and cottonwood (*Populus balsamifera*) with scattered occurrences of young cedar.

The Cedar Swamp area consists of approximately 24 acres is located adjacent to the proposed impact area for Turbine String F.

**Special Status Plants**

**Field Reconnaissance Surveys**

Reconnaissance and inventory surveys were conducted for sensitive species on two occasions. The survey chronology is presented in Table 3.
TABLE 3
Field Survey Chronology for Sensitive Species
Saddleback Wind Project

<table>
<thead>
<tr>
<th>Date</th>
<th>Primary Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>May 28-30, 2003</td>
<td>General habitat survey and survey for spring-blooming rare plant species</td>
</tr>
<tr>
<td>July 28-29</td>
<td>Survey for summer blooming rare plant species</td>
</tr>
</tbody>
</table>

The project study area for potential habitats included the following areas:

- 300-foot corridors centered on all proposed turbine strings and their associated access roads,
- 50-foot corridors on either side of existing all roads proposed for improvement in conjunction with the project,
- an approximately 5-acre plot for proposed substation construction, and
- one 15-acre and two five-acre areas identified as proposed construction staging areas.

Study area boundaries are shown in Figure 1. Field surveys were performed by CH2M HILL botanists and ecologists familiar with rare plant species of the region. Surveys were conducted on May 28-30 and July 28-29, 2003 during optimum time for identification of target species. Total survey area was approximately 302 acres. Potential habitats supporting rare species within the project study area were surveyed on foot at an intensity level sufficient to confirm the presence or absence of targeted rare plant species identifiable at the time of the surveys. The surveyors kept a list of all vascular plants encountered. Observations of plant associations, land use patterns, and unusual habitats were recorded.

Investigation Results

Sensitive Plant Species.

Pre-field Review. The search of the WNHIS database disclosed four rare plant populations documented as currently occurring within 2 miles of the project vicinity (Figure 3):

- branching montia (*Montia diffusa*),
- Suksdorf’s desert parsley (*Lomatium suksdorfii*),
- Siskyou false hellebore (*Veratrum insolitum*), and
- golden chinquapin (*Chrysolepis chrysophylla*).

Three rare plant populations are documented as historically occurring in the project vicinity:

- bolandra (*Bolandra oregana*),
- white-top aster (*Aster curtis*), and
- branching montia.
Insert Figure 3
One plant community identified as a *Known High-Quality or Rare Plant Community and Wetland Ecosystem of Washington* (WNHIS 2003) is documented as occurring within 2 miles of the project site. It is an Oregon white oak/Idaho fescue (*Quercus garryana/Festuca idahoensis*) vegetation community and is located along the drainage of the White Salmon River, approximately ½ mile north of its confluence with the Columbia River.

In addition to the six plants species discussed above, twenty-three additional plant species were added to the survey list, based on the WNHIS list of rare plant species known to occur in Skamania County. Twenty-two of these species were documented by WNHP as occurring within 2 miles of the project site prior to 1977. Rare plant data collected prior to 1977 were vaguely mapped (a five-mile-diameter circle was used to map general location). Rare plant records collected since 1977 are more accurately mapped and have been included in this report. No rare plant species have been documented on the project site since 1977.

The list of potential rare plant species for the project area, identified through prefield review, is presented in Table 4.

**Field Reconnaissance Surveys.** Field reconnaissance surveys failed to locate any rare plant species or plant communities within the proposed project area.

**Environmental Consequences**

**No Build Alternative**

The types and distribution of vegetation would be similar to the existing conditions because land use patterns would be about the same. The age and structure of vegetation in commercial timberland would change over time in a shifting mosaic. It is reasonable to assume that relatively small percentages of existing vegetation types would be affected by roadway maintenance and operations activities, and required modifications to maintain functionality of the roadway.

**Build Alternative**

See discussion of environmental consequences for the Build Alternative under the Wildlife section of this technical memorandum.

**Mitigation Concepts**

See discussion of mitigation concepts for the Build Alternative in the Wildlife section below.

Wetland Delineation Report
Saddleback Wind Energy Project
Skamania County, Washington

PREPARED FOR: Dana Peck/Horizon Wind Energy LLC
PREPARED BY: Joel Shaich /CH2M HILL/PDX
REVIEWED BY: Peggy O'Neill/CH2M HILL/PDX
COPIES: Mike Pappalardo/CH2M HILL/CVO
DATE: January 9, 2007

Summary

CH2M HILL conducted a delineation of potentially jurisdictional wetlands and waters of the State/U.S. and a determination of potential county-required buffer widths adjacent to wetlands and waters within the proposed project areas for the Saddleback Wind Energy Project. The investigation was conducted in the vicinity of Underwood Mountain, approximately 7 miles northwest of the City of White Salmon, in an unincorporated area of Skamania County, Washington (Figure 1). The project area is situated adjacent to, but entirely outside of, the Columbia Gorge National Scenic Area.

Study area boundaries are shown in Figure 2. The project study area for potential wetlands and waters included:

- 300-foot corridors centered on all proposed turbine strings and their associated access roads;
- 50-foot corridors on either side of all existing roads proposed for improvement in conjunction with the project; and
- an approximately 15-acre plot for proposed substation construction, and two 5-acre and five 2-acre areas identified as proposed construction staging areas.

No jurisdictional wetlands or waters of the State/U.S. were observed in the study area. Five sites were identified as potential “drainageways having short periods of spring or storm runoff” that would be subject to county buffer requirements. The five drainageways appear to meet criteria as Type V streams subject to a 25 foot buffer requirement.

This delineation represents the best professional judgment and conclusions of CH2M HILL. It is considered a preliminary jurisdictional determination; final authority for jurisdictional determinations for regulatory permitting rests with the U.S. Army Corps of Engineers and Skamania County Department of Planning and Community Development.
Results

Office Review

USGS Topographic Map

The USGS topographic map shows an intermittent pond identified as "Cedar Swamp" mapped within the general project area but outside of the study areas/proposed project facilities. Three unnamed perennial streams (Cedar Swamp tributaries) are mapped as crossing an existing road that is proposed to be widened to 20 feet. A proposed underground collector line will also follow the road. An unnamed perennial stream is mapped beginning at the western edge of the proposed 15 acre staging area (Figure 2).

National Wetland Inventory (NWI) Map

The National Wetland Inventory map shows one wetland in the general project area (Figure 3). The wetland is classified as a palustrine unconsolidated bottom, semipermanently flooded, dike/impounded (PUBH) wetland and corresponds with the "Cedar Swamp" mapped on the USGS topographic map. It is outside the study areas.

Washington Department of Natural Resources (DNR) Forest Practices Stream Mapping

The Washington Department of Natural Resources Forest Practices Stream Mapping shows ten stream segments that are located within project study areas (Figure 3). These included the streams on the USGS map as well as additional streams. The streams at sites B-1, B-2 and B-3 are unnamed drainages that flow toward the Little White Salmon River. The other streams are unnamed tributaries of Little Buck Creek.

Skamania County Area Soil Survey

A review of the Soil Survey of Skamania County Area, Washington (Haagen, 1990) shows six soil series and 13 types or phases mapped within the project area (Figure 4). None are listed as hydric according the Hydric Soils List for the Skamania County Area, Washington (NRCS, 2001) and none are listed as containing inclusions of hydric soils.

Field Investigation

Wetlands

No wetlands were observed within the study areas. All of the potential stream crossing sites examined for the delineation were dominated by upland species. No wetland hydrology indicators were observed on the surface. Due to the lack of wetland vegetation or hydrology indicators on the surface no sample pits were dug.

Waters of the State/U.S.

Ten sites with potential stream crossings of proposed project facilities were documented in the field delineation and determination of potential buffer widths (Table 1; Figure 3). Site photos are in the Appendix. None of the crossings appear to have waters of the U.S./State present. They did not contain channels or other characteristics of waters.

1.0 Introduction

CH2M HILL biologists conducted surveys for endangered, threatened, and sensitive plant species for the purpose of complying with state and federal permit requirements for the proposed Saddleback Wind project. BPA and Skamania County are the lead federal and state agencies that are responsible for identifying and evaluating the potential adverse environmental impacts of the proposed Project. The investigation was conducted in the vicinity of Underwood Mountain, approximately 7 miles northwest of the City of White Salmon, in an unincorporated area of Skamania County, Washington (Figure 1). The project area is situated adjacent to, but entirely outside of, the Columbia Gorge National Scenic Area.

1.1 Proposed Project Activities

PPM Energy, Inc. (PPM), proposes to build and operate a wind power facility at a site on private commercial forest land and a parcel owned by the Washington Department of Natural Resources (DNR). The planned facility will generate up to 86 megawatts (MW) of electricity and will consist of up to 48, 1.5 to 1.8-MW, wind turbines and associated support infrastructure, consisting of newly constructed and improved roads, transformers, underground 34.5-kilovolt (kV) collector lines, as well as a substation and operations and maintenance (O&M) facility. Collectively, the facility is known as the “proposed Project” or “Project.”

The total project will consist of up to 48 wind turbines. Each turbine will be up to approximately 390 feet tall (measured from the ground to the turbine blade tip), and will be mounted on a concrete pad. Spaced about 347 to 462 feet apart, the turbines will be grouped in strings of 3 to 16 turbines and connected by an underground electrical collector system. The applicant has determined the location and the end points of each turbine string; however, the number of turbines within each string, and the spacing between each turbine, may vary depending on which turbine supplier is selected by PPM Energy. All ultimate turbine siting, spacing, and clear areas will be in accordance with industry standards and safety measures discussed later in this document.

The turbines will operate at wind speeds ranging from 9 to 56 miles per hour (mph). The electrical output of each string of turbines will be connected to the Project substation by underground collector cables. The Project substation will be built directly adjacent to BPA’s transmission lines, facilitating interconnection with the BPA grid. Access to the Project area will likely require use of about 5 miles of private logging roads and constructing about 3 miles of new gravel roads on private land.

1.2 Study Area

The project area is located in the Southern Washington Cascades Province (Franklin and Dyrness 1988). This area is characterized by generally accordant ridge crests separated by
steep, deeply dissected valleys. The project falls within the *Abies grandis* and *Pseudotsuga menziesii* major vegetation zones (Franklin and Dyrness 1988). Climate is wet and cool, receiving a significant portion of its precipitation in the form of snow which accumulates in winter snowpacks as deep as 1 to 3 meters.

The project area is located on the north and west flanks of Underwood Mountain, northwest of White Salmon, Washington. Major drainages in the area include the White Salmon and the Little White Salmon River basins to the east and west of the site respectively. Both basins drain to the Columbia River south of the site, which drains to the Pacific Ocean.

Historically, the project area was dominated by coniferous species—grand fir (*Abies grandis*), and Douglas-fir (*Pseudotsuga menziesii*). Historical species dominance was dependent on elevation, aspect, underlying soil, and previous disturbance history (Franklin and Dyrness 1988). Mixed conifer and deciduous forest stands usually followed disturbances, but occasionally deciduous-dominated stands developed, depending on the disturbance type and physical environment. Typical deciduous species were alder (*Alnus rubra, A. sinuata*), Pacific dogwood (*Cornus nutallii*), and big-leaf maple (*Acer macrophyllum*).

The predominant land use in the surrounding area between Underwood Mountain and the Little White Salmon River is commercial forest production. Land within the proposed project area is currently in commercial timber production and is owned by SDS Lumber Company, Broughton Lumber Company, and the Washington Department of Natural Resources.

Current vegetation conditions are heavily influenced by forest management activities over the last century. Land in the project area is privately owned, managed industrial forest. While forest management has not reduced tree species diversity, it has resulted in a shift in species dominance to the commercially valuable Douglas-fir and in changes to stand structure and complexity, patch size, and species distribution. Average stand age probably declined from relatively short stand rotation ages. Few large, old conifer trees occur in the project area and there are no known late-successional or “old-growth” stands within or adjacent to the project area, though small groups of big trees occur.

Common understory plants include sword fern (*Polystichum munitum*), vanilla leaf (*Achlys triphylla*), false Solomon’s seal (*Smilacena racemosa*), western starflower (*Trientalis latifolia*), Columbia windflower (*Anemone deltoidea*), snowberry (*Symphoricarpos albus*), vine maple (*Acer circinatum*), Oregongrape (*Berberis nervosa*), red-flowering currant (*Ribes sanguineum*), and red elderberry (*Sambucus racemosa*). A list of all plant species observed within the project area is found in Table 1, Appendix A.

The vegetation communities within the project area are common within the region and maintained through forest management, and to a lesser extent natural disturbance. Because of private ownership, rugged landscape, and the value of high-volume timber producing land, these vegetation communities are expected to persist within the region during the foreseeable future.

VICINITY MAP
2.0 Methods

2.1 Pre-field Review

Prior to the field survey, a list of rare plant species potentially occurring within the project area was compiled. In identifying these species a plant was considered a special status species if it met one of the following criteria: federally or state listed or proposed as a rare, threatened, or endangered species (USFWS 1996 a&b); a federal candidate for listing (USFWS 1996 a&b); a Washington Natural Heritage Information System special plant (WNHIS 2003); or listed by the Washington Natural Heritage Program (WNHP) as a rare plant species known to occur in Skamania County (WNHP, March 2003). A species was determined to have some potential for occurring in the study area if it is known to occur in the vicinity or its known geographic range includes the study area, and if it is known to occur in habitats and elevations likely to occur in the study area. Twenty-nine special status species identified from these searches are shown in Table 2, Appendix B.

Further data was collected regarding the habitat requirements, phenology, associated species, and taxonomy of these species. Taxonomic keys, monographs, species guides, and plant lists were collected to provide additional information. Several references were used to gather habitat descriptions for particular species and are noted in the reference section of this report. This information was used to focus the level of survey intensity in areas where site conditions indicated species habitat requirements were present.

2.2 Field Investigation

The purpose of the rare plant surveys was to locate all populations of special status plants within the project area, to precisely record and map their locations using GPS technology, and to determine the size and phenology of each rare plant population, and its microhabitat characteristics. Surveys were floristic in nature and were conducted according to the rare plant survey guidelines provided by the U.S. Bureau of Land Management Survey Protocols for Survey and Manage Strategy 2 Vascular Plants (Whiteaker et al. 1998).

Surveys for potential rare plant species within project area were conducted on May 28, 29, 30 and July 28 and 29, 2003. This range of survey dates was selected to encompass all or a portion of the blooming times of all of the special status plants potentially occurring within the project area. The field surveys were performed by CH2M HILL botanists and ecologists familiar with rare plant species of the region. Potential habitats supporting rare species within the project study area were surveyed on foot at an intensity level sufficient to confirm the presence or absence of targeted rare plant species identifiable at the time of the surveys. The surveyors kept a list of all vascular plants encountered. Observations of plant associations, land use patterns, and unusual habitats were recorded.
Study area boundaries are shown in Figure 2. The project study area for potential habitats included:

- 300-foot corridors centered on all proposed turbine strings and their associated access roads,
- 50-foot corridors on either side of all existing roads proposed for improvement in conjunction with the project,
- an approximately 15-acre plot for proposed substation construction, and
- two 5-acre and five 2-acre areas identified as proposed construction staging areas.

Two survey methods were used. An Intuitive Controlled Survey was conducted throughout the project site with a Complete Survey conducted in areas of high potential habitat. Protocol for these methods is as follows:

**Intuitive Controlled Survey**
For the entire project area an intuitive controlled survey was used. This method can also include a complete survey in habitats with the highest potential for rare plant species of concern.

The surveyor traversed through the project area to see a representative cross section of all the major habitats and topographic features, looking for the target species while en route between different areas. When the surveyor arrives at an area of high potential (that is defined in the pre-field review or encountered during the field visit), a complete survey for the target species is conducted.

**Complete Survey**

For areas where the most suitable habitat was located a complete survey was conducted. These surveys are defined as a 100 percent visual exam of the project area.

All plant species encountered in the survey areas were identified to at least genus and to the level necessary to ensure that they were not special status plant species. Plant identification was aided using current taxonomic guides, including *Flora of the Pacific Northwest* (Hitchcock and Cronquist, 1996) and *Wetland Plants of Oregon and Washington* (Guard, 1995). A list of all plant taxa encountered was recorded in the field by turbine string, road, or staging/substation area. Collections were made for later determination of species that were not readily identifiable in the field. Final species determinations were made by keying specimens using standard references such as *Flora of the Pacific Northwest* (Hitchcock and Cronquist, 1996). A list of plants encountered within the project area during the rare plant survey is provided in Table 1, Appendix A.
FIGURE 2: STUDY AREA
3.0 Results

3.1 Plant Communities

A total of five vegetation types occur within the areas included in project surveys: one wetland and four upland vegetation types. A description of these vegetation types follows.

3.1.1 Wetland Vegetation

Riparian Deciduous. Natural and anthropogenic disturbances frequently result in domination by deciduous species in near-stream areas. Within the project area this type occurs in the area identified on the USGS topographic map as “Cedar Swamp.” Historically this area was dominated by very large, old cedar, which have been logged. The area is now dominated by willow and cottonwood (*Populus balsamifera*) with scattered occurrences of young cedar.

The Cedar Swamp area consists of approximately 24 acres is located adjacent to the proposed impact area for Turbine String F.

3.1.2 Upland Vegetation.

**Grass-forb Stand.** Grass-forb Stands are found in the project vicinity in recently clearcut areas. Grass-forb is the stand condition in the USDA Forest Service classification system defined as areas where shrubs comprise less than 40 percent crown cover and are less than 5 feet tall (Brown, 1985). This stand type occurs when a disturbance such as timber harvest, fires, or wind has killed or removed most or all of the larger trees, or when brush fields are cleared for planting. These units may range from mainly devoid of vegetation to dominance by herbaceous species (grasses and forbs). Tree regeneration in these units is generally less than 5 feet tall and 40 percent crown cover.

In Grass-forb stands within the project vicinity vegetation is minimal and consists predominantly of weedy herbaceous species, including bull thistle (*Cirsium vulgare*), Canada thistle (*Cirsium arvense*), and dandelion (*Taraxacum officinale*). These areas generally consist of ubiquitous coarse woody material (CWM), occasional slash piles, and large areas of bare ground. Within the project’s proposed impact area there are approximately 22.3 acres of grass-forb vegetation community.

**Brushfield/Shrub Stand.** Brushfields are defined as the shrub stand condition in the USDA Forest Service classification system (Brown 1985). They develop on land following clearcut tree harvesting or other disturbances that remove vegetation. In keeping with Washington Forest Practices Rules, Chapter 222 WAC, all harvest units are planted within 3 years after harvest or a period of from 1 to 10 years as determined by the department in the case of a natural regeneration plan and must maintain minimum stocking levels of 150 vigorous, well-distributed undamaged seedlings per acre of commercial tree species.
Thus the majority of brushfields are actually young plantations (typically Douglas-fir, although many landowners are now planting mixed species) that have not yet reached the closed canopy stage or shaded out the shrub species. The type may have large amounts of bare soil, and often has slash and other logging debris on the ground. Vegetation (other than planted conifers) often consists of remnants from the forest understory and early successional annuals. There are vine maple, Sitka alder, beaked hazelnut (*Corylus cornuta*), serviceberry (*Amelanchier alnifolia*), Himalayan blackberry (*Rubus discolor*), bracken fern (*Pteridium aquilinum*), sword fern, oceanspray (*Holodiscus discolor*), fireweed (*Epilobium angustifolium*), wooly yarrow (*Achillea millefollium*), pearly everlasting (*Anaphalis margaritacea*) and grasses as ground cover.

Vegetation control has occurred in conjunction with forest management and includes herbicide application, mechanical control, or both. These areas are visually and functionally different from areas where control has not occurred. Despite control efforts, or where they have not occurred, dense shrub thickets frequently occur, dominated by the native vine maple. Within the thickets are small alders and Douglas-fir that occasionally grow taller than the vine maple. These areas also may have patches of alder saplings, salmonberry (*Rubus spectabilis*), vine maple, red elderberry, oceanspray, lupine (*Lupinus* sp.), Oregon oxalis, and grass. Small diameter coarse woody material (CWM) is common. Within the project’s proposed impact area there are approximately 45.8 acres of brushfield/shrub vegetation community.

**Conifer-Hardwood Forest.** Conifer-Hardwood Forest is found in the project vicinity in the closed sapling-pole stand condition, under the USDA Forest Service vegetation classification system (Brown 1985). The forest canopy in these stands is dominated by a mix of bigleaf maple and Douglas-fir, with some red alder. Canopy height typically ranges from 40 to 60 feet. Canopy closure is between 60 and 80 percent. Maple forms about 30 percent of the canopy cover with Douglas-fir forming most of the rest of the canopy. Stands may have distinct tree canopy layers with deciduous overtopping emerging conifer or remnant conifer over the deciduous component. Stands with shrub layers that merge with the canopy layers are found in the project vicinity. The shrub layer varies from open to dense and contains vine maple, salmonberry, thimbleberry (*Rubus parviflora*), red elderberry, beaked hazelnut, and Pacific dogwood. The herbaceous layer contains sword fern, trailing blackberry, oxalis, grasses, and moss. Within the project’s proposed impact area there are approximately 147.9 acres of conifer-hardwood vegetation community.

CWM is dependent on stand age, but is typically low to moderate. Deciduous snags outnumber conifer snags, although depending on stand origin, short well decayed conifer snags may be present.

**Conifer Forest.** Coniferous Forest is found in the project area in closed sapling-pole-sawtimber stands and large sawtimber stands. Within the project area and most of the region, Coniferous Forests are dominated by Grand fir and Douglas-fir. The closed sapling-pole-sawtimber is a continuum of tree diameter sizes with saplings being relatively small, poles being in the 8-12 inch range, and sawtimber ranging from 12 to 23 inches. Important to these stand types is the closed canopy and relative short live crowns found in the pole and sawtimber stages. The closed canopy results in the exclusion of most shrub species and many herbs.
CWM in this stage is typically low and consists of remnants from previous stands. Snags are typically rare, although small diameter snags become more frequent in the pole and sawtimber stages as shading and resource competition kills subdominants.

Large sawtimber is considered to be at least 21 inches in DBH. Within-stand differentiation has begun and dominants are beginning to overtop and out-compete other tree species. Competition for space results in more light reaching the forest floor and shrub and herbaceous communities typically become more diverse. CWM and snags are generally rare, although the number of snags and amount of CWM may be variable amount stands, dependent on past harvest practices, stand management, and actual stand age.

These forests are used for commercial forestry, and are generally regenerated after harvest, although some may be the result of natural disturbance combined with commercial planting. They are subject to timber management activities including harvest, replanting, and stand improvement activities. These forests are widespread in the project vicinity. Within the project’s proposed impact area there are approximately 85.8 acres of conifer vegetation community.

### 3.2 Rare Plants

No special status plant species were observed within the proposed project area in the course of the rare plant surveys.

<tr>
<td>Brassicaceae</td>
<td>Rorippa</td>
<td>persistentsepal yellowcress</td>
<td>April to October (depending on water regime)</td>
<td>Has been observed near all types of bodies of water, including the Columbia River, intermittent snow-fed streams, permanent lakes, snow-fed lakes, internally-drained lakes, which may be dry for extended periods of time, wet meadows, irrigation ditches, and roadside ditches. The species apparently requires wet soil throughout the growing season. It is known from a wide variety of soil types, including clay, sand, gravel, sandy silt, cobbles, and rocks. Individuals are usually found in open habitats that have low vegetative cover. A common feature of all of the known sites is inundation for at least part of the year. R. columbiae typically occurs in the lowest vegetated riparian zone in a band spanning approximately 1-1.5 meters in elevation.</td>

<tr>
<td>Fumariaceae</td>
<td>Corydalis</td>
<td>Clackamas corydalis</td>
<td>June to September</td>
<td>Occurs primarily in the western hemlock (Tusga heterophylla) and Pacific silver fir (Abies amabilis) zone. (Franklin and Dyrness, 1973), at elevations ranging from 2500 to 3800 feet. It is found growing in or near cold flowing water, including seeps and small streams, often occurring within the stream channel itself. Current information suggests that C, aquae-gelidae prefers intermediate levels of overstory canopy closure which provide enough light for flowering and reproduction, yet not so much light that a dense cover of shrubs develops.</td>

<tr>
<td>Iridaceae</td>
<td>Sisyrinchium</td>
<td>pale blue-eyed grass</td>
<td>mid-June to early August</td>
<td>Occurs in meadows and small openings from 1600 to 4200 feet. The meadows, which fill with snow and/or water I winter and spring, area variously dominated by grasses and sedges. Conifers such as lodgepole pine (Pinus contorta), and Engelmann spruce (Picea engelmannii), and shrubs such as hardhack (Spiraea douglasii), border the meadows and are occasional invaders. The sites are relatively flat, often being slightly concave. Most sites are within either the Little White Salmon River or the White Salmon River drainages. The underlying bedrock is basalt from various flows.</td>

<tr>
<td></td>
<td><em>Botrychium minganense</em></td>
<td>Mingan grape-fern</td>
<td>May through July</td>
<td>Exhibits wide ecological amplitude, occurring in a wide range of habitats, particularly east of the Cascades, where it occurs in open shrubland and barren slopes. However, it typically occurs in older forest stands. The colonies are associated with riparian zones and old growth western redcedar (<em>Thuja plicata</em>) in dense shade, sparse understory, on alluvium substrate and often a duff layer of <em>Thuja</em> branchlets. Generally occur on soils saturated in the Spring, but tend to dry out later in the growing season. Plants do not occur in soils wet enough to support skunk cabbage, but grow adjacent to these areas.</td>

Scrophulariaceae

| Collinsia sparsiflora var. bruceae | few-flowered collinsia | mid-March through April | In Washington, the taxon occurs in thin soils over basalt on a variety of slopes, from almost flat to rather steep, generally south-facing. The microsites are generally quite open, but may be adjacent to or found within open stands of ponderosa pine and Oregon white oak. These habitats are moist in spring, but become dry by summer. | Dodecatheum dentatum, Tolmiea menziesii, Oxalis trillifolia. | Threatened | SC | WNHP (2002) |

| Penstemon barrettiæ | Barrett's beardtongue | late April to early June | In Washington, P. Barrettiæ generally grows in crevices along basalt cliff faces, on ledges of rock outcrops, on open talus and occasionally along well drained roadsides. It occurs mostly at lower elevations, but its range is up to 3200 feet. It generally occurs on rocky substrates of basaltic origin, with little soil development. Soils area composed of wind blown material and organic matter and provide good drainage. | Psuedotsuga menziesii, Pinus ponderosa | Threatened | SC | WNHP (2001) |

</thead>
<tbody>
<tr>
<td><strong>Asteraceae</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>Balsamorhiza</em></td>
<td>Puget balsamroot</td>
<td>Perennial with a deep-seated, woody taproot and multicipital caudex; basal leaves long-petiolate, the blade mostly triangular-hastate, or with more cordate base, up to 30 cm. Long and 20 mm wide, green, inconspicuously hirsute and often glandular, thinner and less veiny than in <em>B. careyana</em>, often crenate; stem 2-10 dm tall, scapiform, but usually with several strongly reduced narrow leaves; central head large, the disk rarely less than 2.5 cm wide; lateral heads, when present, obviously smaller; involure only slightly or scarcely wooly, the outer bracts tending to be enlarged and foliaceous, surpassing the disk' rays commonly about 13 or about 21 (fewer on the reduced lateral heads), 2-5 cm long, soon deciduous, not becoming papery; achenes glabrous.</td>
</tr>
<tr>
<td></td>
<td><em>Erigeron howellii</em></td>
<td>Howell's daisy</td>
<td>Perennial from a rhizome, 8 to 20 inches tall, scantily short-villous under the heads. Leaves thin, glabrous, the lowermost ones with elliptical or suborbicular blade 1 to 3 inches long and 1/2 to 2 inches wide, abruptly contracted to the 3/4 to 5 inch petiole. Middle cauline leaves ample, ovate to cordate, strongly clasping at the base; upper leaves similar but smaller. Heads solitary, the disk 1/2 to 3/4 inch wide. Involucral bracts loose, equal, glandular, somewhat herbaceous. Rays 30-50/2 to 1 inch long, 1/16 to 1/8 inch wide, white. Disk corollas 1/8 to 1/4 inch long, more flaring than in <em>E. peregrinus</em>. Achenes mostly asymmetrically 5-nerved. Pappus of 20-30 capillary bristles.</td>
</tr>
<tr>
<td></td>
<td><em>Erigeron oreganus</em></td>
<td>Gorge daisy</td>
<td>Perennial with a stout mostly simple caudex and stout root; herbage glandular and loosely viscid-villous; stem lax, 5-15 cm long; basal leaves tufted, spatulate to obovate, coarsely toothed or incised, up to 9 cm long and 2.5 cm wide; cauline leaves well developed, broadly lanceolate to elliptic or ovate, up to 4 cm long and 1 cm wide; heads 1-severa in a leafy inflorescence, the disk 9-13 mm wide; involucre 5-7 mm high, glandular and viscid-villous, the bracts loose, equal, thin, green; rays mostly 30-60, bluish to more often pink or white; 5-8 mm long; disk corollas usually 3.4-4.7 mm long; pappus simple, of about 15-20 bristles which are characteristically curled and twisted for at least the upper half.</td>
</tr>
<tr>
<td></td>
<td><em>Microseris borealis</em></td>
<td>northern microseris</td>
<td>Perennial (with stout taproot). Stems leafless with solitary flower head. Leaves with minute teeth on margins.</td>
</tr>
<tr>
<td><strong>Boraginaceae</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><em>Hackelia diffusa var.</em></td>
<td>diffuse stickseed</td>
<td>Perennial 1 2/3 to 2/12 inches tall. Stems few, erect or ascending, internodes long near the base, short near midstem, the plant therefore appearing leafy near the middle. Pubescence strongly spreading, hirsute, becoming antrorsely appressed in the inflorescence. Radial leaves few to many, 5 to 9 inches long, 1/2 to 1 inch wide, elliptic, petiolate for 1/3 their length, hirsute, all but the lowermost cauline leaves sessile, the lower ones 3 2/3 to 6 inches long, 1/2 to 2/3 inch wide, elliptic, becoming lanceolate or linear-lanceolate above, at mid-stem 2 1/2 to 4 inches long and 1/4 to 1/3 inch wide. Pedicel 1/4 to 1/3 inch long in fruit. Calyx 1/8 inch long, lanceolate or linear-lanceolate. Corolla limb blue or cream, with a yellowish throat, 1/4 to 1/2 inch wide. Fornices with appendages papillate-puberulent to short pilose, not always evidently emarginate. Anthers 1/16 inch long. Nutlets 1/8 inch long, ovate, dorsal surface rough, verrucose-hispidulous, the intramarginal prickles distinct, 10. Prominent marginal prickles distinct to their bases, 1/16 to 1/8 inch long, these alternating with 1-3 short barbs.</td>

<th>Family</th>
<th>Scientific Name</th>
<th>Common Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Brassicaceae</td>
<td><em>Rorippa columbiae</em></td>
<td>persistentsepal yelloweress</td>
<td>Low-growing perennial with stems that usually are 4-12 inches long. The stems generally grow flat on the ground but are sometimes erect and much-branched. The stems arise from underground stems and rhizomes and can at times form large clusters of stems. The leaves are divided almost to their center into several pairs of opposite leaflets, and sometimes have small teeth on the edge. Flowers are borne both on the ends of the stems and in the axis of leaves. The flowers are approximately 1/3 inch wide and have four bright yellow petals, which are about 1/10 inch long. The sepals are flat and ovate to oblong and tend to persist through fruiting. The fruits are almost oblong and are 1/4 inch long and are usually larger than the flowers.</td>
</tr>
<tr>
<td>Campanulaceae</td>
<td><em>Githopsis specularioides</em></td>
<td>common blue-cup</td>
<td>Annual herb with branched or unbranched stems up to 12 inches tall. In Washington it has usually been observed to be less than 6 inches tall. The plants are leafy stemmed, and the narrow, toothed, alternate leaves are sessile, up to 2/3 inch long and 1/16 inch wide. Flowers occur single, and are irregularly scattered on the upper stems, or are strictly terminal on small, unbranched plants. Flowers are deep blue, with a whitish throat, 3/8 inch long or less. Flowers have five lobes, and the lobes are about as long as the flower tube. The sepals, 1/4 to 1/2 inch long, tend to obscure the flowers from view.</td>
</tr>
<tr>
<td>Caryophyllac</td>
<td><em>Silene douglasii. var. monantha</em></td>
<td>Douglas' silene</td>
<td>Caespitose perennial with a stout taproot, branched caudex, and numerous decumbent simple stems 1-4 (7) dm tall, finely and densely pubescent throughout with crisped and usually retrorse hairs, very rarely slightly glandular above; leaves mostly matted at the base of the stems and on the new shoots, narrowly to broadly oblanceolate to linear-lanceolate, mostly 2-5 (8) cm long, 2-7 (12) mm broad, acute, long-petiolate; cauleine leaves 1-8 pairs, becoming smaller and sessile above; flowers usually 1-7, linear-bracteate, cymose, the lower ones sometimes remote from the terminal; calyx tubular, (10) 12-15 mm long, becoming inflated, papery, and tubular-campanulate in fruit, 10-nerved, usually thickly puberulent, less commonly nearly glabrous, very rarely somewhat glandular; corolla creamy-white or greenish, pink, or purplish-tinged; claw of the petals 8-12 mm long, sometimes auriculate, the blade oblong, 4-6 (8) mm long, bilobed 1/5 to 1/3 of the length but otherwise usually entire (very rarely with a small lateral tooth on each margin below the sinus); appendages 2, linear or oblong, 1 (3) mm long; carpophore 3-4 mm long, finely puberulent; styles 3 (4 or 5); capsule 1-celled; seeds about 1.3 mm long, rugose-tessellate, the margins more prominently rounded-papillate.</td>
</tr>
<tr>
<td>Cyperaceae</td>
<td><em>Carex macrochaeta</em></td>
<td>large-awn sedge</td>
<td>Stems loosely clustered on a system of short, branching rhizomes, 1-7 dm tall, aphyllopodic; roots pubescent, covered with a yellowish-brown felt; leaves rather few, flat, mostly 2-5 mm wide, glabrous, evidently to obscurely white-papillate on the lower surface; staminate spike solitary (seldom 2 or 3), terminal, 1-3 cm long, with black or dark brown, awn-tipped scales; pistillate spikes (1) 2-4, not crowded, the lowest one loose or nodding on a slender, flexuous, often elongate peduncle and subtended by a leafy bract which may or may not surpass the inflorescence and which is sheathless or has a short sheath up to about 5 mm long; upper pistillate spikes shorter-pedunculate or even sub-sessile, with shorter and less-foliaceous subtending bracts; pistillate scales black or sometimes merely dark purple or brown, often with a paler mid-vein, the body shorter or sometimes long than the perigynium, usually narrower distally than the perigynium, distinctly awn-tipped, the awn sometimes as much as 1 cm long, always at least some of the awns in the spike 2 mm long or more; perigynium glabrous, narrow, commonly lance-elliptic, light green or sometimes partly or wholly dark purplish, 10- to 15-nerved, 3.3-4.8 mm long, beakless or with a very short beak seldom over 0.2 mm long; stigmas 3; achene trigonous, 1.7-2.3 mm long, loosely enclosed in the lower half or three-fifths of the perigynium.</td>

<td><strong>Chrysolepis</strong></td>
<td>golden chinquapin</td>
<td>Large shrub or small tree (3) 5-30 m tall, the bark thick and heavily furrowed; leaves with petioles scarcely 1 cm long, the blades lanceolate to oblong-lanceolate or -elliptic, (3) 5-10 cm long, entire, thick and coriaceous, dark green and glabrous or sparsely scurfy-tomentose above, yellow-green to golden and densely scurfy-tomentose beneath, the vase acute, gradually to abruptly acuminate; involucre a 4-valved, spiny bur 1.5-2 cm broad, containing 1 (2) hard-shelled nuts about</td>
</tr>
<tr>
<td>Fumariiaceae</td>
<td><strong>Corydalis</strong></td>
<td>Clackamas corydalis</td>
<td>Perennial from deep-seated, fleshy roots, the stems succulent and strongly fistulose, 12 to 44 inches tall, simple to branched; leaves several, yellowish-green, glaucous on the lower surface, the lower cauleine ones up to 24 inches long often equaling the racemes, from 4 to 6 times pinnate, the ultimate segments very numerous, more or less elliptic, 3/16 to 1/2 inch long and 1/16 to 3/16 inches broad; racemes simple to compounded, conspicuously bracteate, rather compactly 30 to 60 flowered, ultimately elongate and up to 9 inches long; corolla 1/2 to 3/4 inch long, pale to deep pinkish with a slight trace of purple, the inner petals more deeply colored at the tip; spurred petal conspicuously crested, usually without free margins or the margins very slightly upturned; spur 3/8 inch long; capsule ellipsoid, 3/8 to 1/2 inch long, about 1/3 as thick, the style 1/4 to 1/2 as long; seeds about 1/16 inch long.</td>
</tr>
<tr>
<td>Iridaceae</td>
<td><strong>Sisyrinchium</strong></td>
<td>pale blue-eyed grass</td>
<td>Perennial herb up to 12 inches tall, although generally it is only 6 to 8 inches in height. The leaves are narrow and area generally, but not always, shorter than the stem. Both the stems and leaves are a pale green or blue-green color. Each stem has 2-7 flowers on slender pedicels. The perianth is pale blue with a yellow spot in the center. The tepals are about 1/2 inch in length and pale blue in color. The anthers are yellow. A technical description needs to be consulted for positive</td>
</tr>
<tr>
<td>Juncaceae</td>
<td><strong>Juncus howellii</strong></td>
<td>Howell's rush</td>
<td>Rhizomatous perennial 2-6 dm tall, the stems slightly compressed, exceeding the leaves; sheaths with membranous margins freed above and forming erect auricles 1-3 mm long; blades 2-4 mm broad dorsiventrally flattened, grasslike, nonseptate; heads (2) 3-9, in a terminal inflorescence 2-9 cm long, each head 3- to 8 (15)-flowered, 7-17 mm broad (pressed); involucral bract rarely as much as 15 mm long; perianth segments lanceolate-acuminate, 5-6.5 mm long, subequal, medium- to chestnut-brown with a broad greenish midstripe, usually minutely papillose toward the tip (under 20X magnification); stamens 6, the anthers 1.8-2.6 mm long, much longer than the filaments; capsule ovoid, 0.5-0.7 mm long, covered with a strongly reticulate membrane that forms a conspicuous appendage at each end.</td>
</tr>
<tr>
<td>Lentibulariac</td>
<td><strong>Utricularia intermedia</strong></td>
<td>flat-leaved bladderwort</td>
<td>Submersed plants with very slender stems, commonly creeping along the bottom; leaves numerous, alternate, mostly 1/4 to 3/4 inch long, commonly 3-parted at the base and then 1-3 time dichotomous, the segments often unequal, slender, flat, not much narrower in successive dichotomies, the ultimate ones rather blunt; blades borne on specialized branches distinct from the leaves, 1/16 to 3/16 inch wide; winter buds ovoid or ellipsoid, 3/16 to 18 inch long, flowers mostly 2-4 in lax racemes at the end of an emergent peduncle 2 1/2 to 8 inches long; corolla yellow, the proper tube very short, the lower lip commonly 1/3 to 1/2 inch long, with a well-developed palate; upper lip not much more than half as long as the lower; spur nearly as long as the broad, slightly lobed lower lip; fruiting pedicels sub erect.</td>
</tr>

</table>
## TABLE 3  Special Status Plant Descriptions
### Saddleback Wind Project

<table>
<thead>
<tr>
<th>Family</th>
<th>Scientific Name</th>
<th>Common</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lycopodiaceae</td>
<td>Lycopodiella inundata</td>
<td>bog clubmoss</td>
<td>Main stem annual, more or less elongate, prostrate or arching, irregularly rooting, leafy, giving rise to scattered, erect, leafy branches, each of which is up to about 1 dm tall and terminates in a cone 1.5-4 cm long; plant perennating by a winter bud; leaves crowded, in 8-10 ranks, think, narrow, mostly entire, 4-8 mm long and less than 1 mm wide, broadest near the base, tapering gradually to the softly acicular tip, the ones on the lower side of the main stem twisted into a more or less erect position, those of the erect stems loosely ascending; sporophylls numerous, crowded, expanded at the base, otherwise resembling the vegetative leaves, the long, slender, green tips loosely ascending; sporangia ellipsoid-globose, about 1 mm wide; spores 43 microns or more in diameter, rounded-triangular or nearly circular in outline, the outer face irregularly ridged-reticulate, the commissurals faces papillate, the commissurals in furrows; gametophyte cylindrical, erect, with distal filamentous lobes, distally emergent and photosynthetic.</td>
</tr>
<tr>
<td>Ophioglossac</td>
<td>Botrychium lunaria</td>
<td>moonwort</td>
<td>Plants (3) 6-18 (22) cm tall, glabrous throughout; sterile blade sessile or on a short stalk up to about 5 mm long, about equaling or more often somewhat shorter than the common stalk, which is (1.5) 4-10 cm long, the blade itself mostly 1.5 to 7 cm long and 0.7 to 3 (3.5) cm wide, distinctly pinnate, with (2) 3-6 (7) pairs of pinnae, these sessile, dichotomously veined, without a midrib, broadly flabellate, broader than long, crowded and often somewhat overlapping, the lowest pair not notable different from the next pair; fertile stalk and fruiting spike each 0.5 to 7 cm long, subequal or either one longer than the other; both the sterile blade and the fertile spike erect or nearly so in bud; bud glabrous, completely hidden by the sheathing base of the common stalk.</td>
</tr>
<tr>
<td></td>
<td>Botrychium minganense</td>
<td>Mingan grape-fern</td>
<td>A small, herbaceous perennial fern. The sterile blade (trophophore) is dull green in color, narrowly oblong to linear in overall outline, about 10 cm long by 2.5 cm wide. The sterile blade is once-pinnate, with up to 10 pairs of pinnae. In general the segments are well-developed, cuneate to flabellate in shape, and spaced separately from each other along the rachis. The margins of the pinnae are entire to shallowly crenate. The lowest pinnae are narrowly fan-shaped. The above-ground or visible parts of this species consist of a single upright stem arising from the ground and terminating in a cluster of tiny ball-like structures that resemble a bunch of grapes. Branching off from the main stem is the sterile, fern like leaf blade (the trophophore). At the base of the common stalk, but just below the ground, are several layers of leaf primordia that are the preformed buds of plants that will emerge in future years.</td>
</tr>
<tr>
<td></td>
<td>Botrychium pinnatum</td>
<td>St. John's moonwort</td>
<td>Plants mostly 1-2 dm tall, glabrous from the first, commonly yellow-green; sterile blade attached near or more commonly above the middle of the plant (the common stalk mostly 4-13 cm long) sessile or nearly so, mostly ovate or ovate-oblong in outline, mostly 2-5 cm long and 1.5-4 cm wide, somewhat fleshy, evidently veiny, bipinnate or subbipinnate (at least toward the bade), the pinnae mostly 3-6 pairs, the ultimate segments rounded, not much if at all longer than wide, somewhat crowded; fertile stalk mostly 1-4 cm long, the fertile spike 1.5-6 cm long, erect even in bud; sterile blade erect in bud except for the inclined but not clasping tip; bud glabrous, wholly concealed by the base of the common stalk.</td>

<tr>
<td>Orchidaceae</td>
<td><em>Cypripedium fasciculatum</em></td>
<td>clustered lady's slipper</td>
<td>Perennial herbaceous plant with a single erect stem 2-8 inches tall and a single pair of broad, parallel-veined, pleated leaves at or above the middle of the stem, which is covered with wooly hairs. Flowers droop in a tight cluster of 2-4 at the tip of the stem and consist of greenish-brown or greenish-purple petals and sepals, usually purple-lined or mottled, and a greenish-yellow pouch with brownish-purple margins, often with a purplish tinge. The stem above the leaves becomes erect and elongates as the capsules develop.</td>
</tr>
<tr>
<td></td>
<td><em>Plantathera sparsifolia</em></td>
<td>canyon bog-orchid</td>
<td>Plant glabrous, 12 to 32 inches tall, the stems leafy mostly on the lower half. Leaves narrowly oblong-lanceolate, up to 10 inches long and mostly 1/2 to 1 1/4 inches broad. Raceme much elongate and usually very lax flowered, 6 to 16 inches long, the first several flowers rarely overlapping. Bracts usually shorter than the flowers but the lowermost sometimes considerably longer. Flowers greenish. Upper sepal broadly ovate to suborbicular, blunt, concave and converging with the upper petals to form a distinct hood, 1/4 to 1/3 inch long, 3-nerved. Lateral sepals spreading, falcately oblong-lanceolate, 1/4 to 1/2 inch long, 3-nerved. Lip pendent, thickish, linear to linear-lanceolate, 1/4 to 1/2 inch long. Spur cylinic to slightly clavate and mostly abruptly narrowed at the tip, from slightly shorter to somewhat longer than the lip, mostly somewhat curved. Column rather large, well over half as long as the upper sepal, the pollen sacs 1/16 inch long, well-separated by the connective.</td>
</tr>
<tr>
<td></td>
<td><em>Spiranthes porrifolia</em></td>
<td>western ladies-tresses</td>
<td>Terrestrial, glabrous 8-20 inches tall; leaves 3 to 5, elliptic-lanceolate, basal or on lower portion of stem, sometimes absent at flowering time; stems with a few bracts above the leaves; inflorescence a dense spiral of up to forty small yellowish flowers in several vertical ranks; floral bracts lanceolate, 1/2 inch long; dorsal sepal lanceolate, 1/2 inch long; dorsal sepals lanceolate, lateral sepals similar but oblique; petals linear-lanceolate; lip ovate, not expanded at apex, base with prominent protuberances; column 1/16 inch long with dorsal anther; ovary sessile, stout, 1/16 inch long.</td>
</tr>
<tr>
<td>Polemoniace</td>
<td><em>Polemonium carneum</em></td>
<td>great polemonium</td>
<td>Perennial with loosely clustered (sometime solitary) stems from a woody rhizome or caudex, loosely erect, 3-10 dm tall, viscid-villous in the inflorescence, otherwise glabrous or nearly so except for the villous-ciliate margins of the petioles or the lower portion thereof, or sometimes the stem viscid-villous throughout; leaflets mostly 11-19, lanceolate to ovate or elliptic, generally acute, thin, mostly 1.5-4.5 cm long and 6-23 mm wide, the 3 terminal ones sometimes partly confluent; basal leaves long-petiolate, cauleine progressively less so, long-pedicellate, in an open terminal, generally leafy inflorescence; calyx 7.5-14 mm long at anthesis, the lobes shorter or longer than the tube; corolla campanulate, (15) 18-28 mm long, the lobes longer than the tube, variable in color, often flesh-colored, salmon, or yellow, sometimes lavender to</td>
</tr>
<tr>
<td>Portulacaceae</td>
<td><em>Montia diffusa</em></td>
<td>branching montia</td>
<td>Low, spreading, diffusely (more or less dichotomously) branched annual, up to 3-4 dm broad and as much as 1.5-2 dm tall; basal leaves few, the blade lanceolate or rhombic-lanceolate to suborbicular, mostly 1-2.5 cm long, often nearly as broad, abruptly narrowed to a petiole 2-4 time as long; cauline leaves alternate, not greatly reduced even in the inflorescence, usually more or less lanceolate-rhombic, the lower ones with blades sometimes as much as 5 cm long; racemes often ancillary to ordinarily foliage leaves, clustered and paniculate toward the branch ends, the lower 1 or 2 of the several flowers often from the axil of a leafy bract; sepals 2-3 mm long, unequal; petals white or pale pink, 3-4 mm long; stamens 5; capsule equaling or slightly exceeding the sepals, obovoid-pointed, 3-valved; seeds usually (1) 2-3, black, finely and regularly papillate with low, oval protuberances, 1.2-1.5 mm long, with a short conical strophiole nearly 0.5 mm long.</td>

<tbody>
<tr>
<td>Ranunculace</td>
<td><em>Cimicifuga elata</em></td>
<td>Tall bugbane</td>
<td>Tall woodland perennial with large expansive, bi- and triternate-toothed leaves. The leaves are downy-hairy above, smooth below and usually arranged in clusters of three, with 9-17 leaflets. The leaflets have 5-7 lobes, coarsely toothed margins and are similar in shape to maple leaves. Stem leaves gradually become smaller as the height of their attachment increases. Plants usually have a single, sometimes branched flowering stem, 3-6 feet tall, from a horizontal rhizome that is up to 4 inches long and 1 inch in diameter. The long, open racemes consist of many 1/4 inch white flowers whose sepals drop at once, giving the appearance of a &quot;bottle brush&quot; of long white stamens and pistils. As its fruits mature, the terminal raceme often becomes declined at a 45-90 degree angle from the axis of the main stem. The fruit is a dry flat capsule containing approximately 10 red to purple-brown seeds. Each flower usually produces 1 capsule; occasionally 2 or 3 capsules are produced. Somewhat similar to false bugbane (<em>Trautvetteria caroliniensis</em>) with tall (1-2 m), branched stems, large compound leaves (somewhat like those of <em>Actea rubra</em>), numerous small, white-stamened flowers in a narrow, terminal, branched inflorescence, and several-seeded follicles.</td>
</tr>
<tr>
<td>Saxifragacea</td>
<td><em>Bolandra oregana</em></td>
<td>Bolandra</td>
<td>Weakly glandular-pubescent, herbaceous perennial with numerous bulblets along the very short, horizontal rootstocks, the stems mostly single, (1.5) 2-4 (6) dm tall; basal and lower cauline leaves with slender petioles up to 15 cm long, the blades reniform (2) 3-7 cm broad, shallowly lobed and with 9013 acutely dentate or usually somewhat serrate-dentate segments; petioles much shortened on the upper leaves and the stipules much more conspicuous and leaflike; bracts of the inflorescence somewhat clasping, 1-3 cm long, deeply crenate-dentate' panicle branches (1) 2-7, remote, spreading, 1-7 flowered; calyx accrescent and eventually 14-18 mm long, the linear-lanceolate, usually purplish lobes equaling or slightly exceeding the campanulate-tubular portion; petals purplish, linear, about equal to the calyx lobes, the stamens about 1/3 as long, the filament reddish-purple; capsule about 1 cm long, the carpels fused only 1/5 to 1/4 their length.</td>
</tr>
<tr>
<td></td>
<td><em>Parnassia fimbriata</em></td>
<td>Fringed grass-of-parnassus</td>
<td>Rootstock short, rather stout, from slightly ascending to nearly erect; flowering stems 1-several, mostly 1.5-3 (5) dm tall. The bract cordate and more or less clasping, mostly 5-15 (20) mm long, borne from slightly below to considerably above midlength of the scape; petioles (1) 3-10 (15) cm long; leaf blades (1.5) 2-4 (5) cm broad, mostly reniform or somewhat reniform-auriculate and broader than long, but not uncommonly more nearly cordate or truncate at base, and sometimes slightly cuneate and somewhat longer than broad; calyx fused with the ovary for only about 1 mm, the segments obovate-ovate, 4-7 mm long, usually 5 (7) -veined, entire or more commonly crenulate-fimbriate, at least toward the rounded tip; petals white, 5- to 7-veined, 8-12 mm long (about twice as long as the calyx lobes, more or less cuneate-obovate in general appearance but claw-like at the base and with numerous long, filiform-linear, plainly cellular-verrucose fimbriae, becoming more or less erose to entire on the upper half; staminodia thickened and scalelike, flared above the middle and usually with a central, subterminal, larger lobe and 7-9 marginal, short, thick, rounded lobes, but sometimes with 5-many elongate, slender, capitulate-tipped segments; filaments stout, about equaling the calyx segments, anthers 2-2.5 mm long; capsule ovoid, about 1 cm long. Variety hoodiana: Staminodia ending in longer, more slender, filamentlike, usually capitulate segments. Segments of the staminodia mostly less than 10, slender, strongly capitate, all marginal, equaling (or longer than) the rather narrow basal scale.</td>
</tr>
<tr>
<td></td>
<td><em>Sullivantia oregana</em></td>
<td>Oregon sullivantia</td>
<td>Delicate, yellowish-green perennial spreading by long slender stolons, nearly or quite glabrous except for some glandular pubescence on the upper portion of the flowering stems and on the inflorescence, the hairs mostly purplish-tipped. The basal leaves are long-petiolate, the blade reniform, 1/2 to 4 inches broad, incisely lobed to 1/2 their length into 7 to 9 cuneate segments and again once or twice sharply toothed. Flowering stems 2 to 8 inches tall with 1 to 3 leaves that are greatly reduced upward. Flowers erect, but becoming sharply reflexed in fruit. Calyx glabrous, pale green, 1/10 to 1/8 inch long, more or less campanulate. Petals slightly long than the calyx lobes, the blade oval to obovate-oblancoate, narrowed to a very short, broad claw. Stamens shorter than the sepals, the corolline anthers about equaling the slender filaments. Capsule about 1/8 inch long, seeds brown 1/16 inch long.</td>

</tr>
<tr>
<td>Scrophularia</td>
<td><em>Collinsia sparsiflora</em> var. <em>bruceae</em></td>
<td>few-flowered collinsia</td>
<td>Plants annual, 2 to 8 inches tall, simple or often branched, erect, glabrous or minutely spreading-hirtellous. Leaves opposite throughout, the lower petiolate, with broadly elliptic or ovate to subround, often few-toothed blade about 1/2 inch long or less, often deciduous, the others narrow and becoming sessile, commonly linear to linear-oblong or linear-lanceolate, mostly entire, up to about 1 1/4 inches long and 1/4 inch wide. Flowers long-pedicellate, 1-3 at each of the upper nodes, their subtending leaves more or less reduced. Calyx 1/4 to 1/2 inch long, the lanceolate to narrowly lance-triangular, acute to acutish lobes prominent, firm-foliaceous, much longer than the tube, commonly concealing much of the corolla tube. Corolla blue-lavender or often white, 1/3 to 1/2 inch long, the tube abruptly bent near the base, forming and oblique angle with the calyx and strongly enlarged on the upper side at the bend. Keel generally somewhat hairy externally near the tip. Upper pair of filaments shortly spreading-hairy over most of their length. Capsule subglobose, 1/8 to 1/4 inch wide. Sees flattened, irregularly wing-margined, evidently cellular-reticulate, 1/8 inch long. Can be distinguished from other species of Collinsia by the following characters: upper filaments pubescent rather than glabrous; calyx nearly as long or as long as corolla; capsule subglobose rather than ellipsoid; seed flattened with a narrow wing margin, rather than turgid with a thickened margin, or flattened with a wide margin.</td>
</tr>
<tr>
<td></td>
<td><em>Penstemon barrettiae</em></td>
<td>Barrett's beardtongue</td>
<td>Medium-sized perennial herb with stems 8-16 inches tall, much branched and somewhat shrubby at the base. The leaves area evergreen, thick, leathery or succulent, bluish- to grayish-green, and toothed along the margins. The rose-purple flowers are 1 to 1 1/2 inches long, tubular, and strongly two-lipped at the end. The flowers are approximately 1/2 inch wide at the mouth, and hairy on the inside of the lower lip.</td>

EXECUTIVE SUMMARY

SDS Lumber has proposed a wind-energy facility in Skamania County, Washington, near the town of White Salmon. SDS Lumber contracted Western EcoSystems Technology, Inc. to conduct surveys and monitor wildlife resources in the Whistling Ridge Wind Resource Area to estimate the impacts of project construction and operations on wildlife. The following document contains results for fixed-point bird use surveys and incidental wildlife observations.

The proposed wind-energy facility contains minimal habitat diversity. Approximately 82.0% of the 1,151-acre (1.8 square mile; 4.7 square kilometer) area is composed of evergreen forest. The next most common habitat is developed open space, which comprises 8.5% of the Whistling Ridge Wind Resource Area. Shrub-scrub habitat comprises 7.1% and grassland areas comprise 1.8% of the study area. All other habitats collectively comprise less than 1% of the Whistling Ridge Wind Resource Area.

The principal objectives of the study were to: 1) provide site specific bird resource and use data that would be useful in evaluating potential impacts from the proposed wind-energy facility; 2) provide information that could be used in project planning and design of the facility to minimize impacts to birds; and 3) recommend further studies or potential mitigation measures, if warranted.

The objective of the fixed-point bird use surveys was to estimate the seasonal, spatial, and temporal use of the study area by birds, particularly raptors. Fixed-point surveys were conducted from September 11, 2004 through November 4, 2004, May 21, 2006 through July 14, 2006, and again in December 4, 2008 through May 29, 2009. A total of 261 20-minute fixed-point surveys were completed and 86 bird species were identified.

Waterfowl use only occurred during spring (0.07 birds/plot/20-min survey), and consisted of a single group of Canada geese. Raptor use was highest during the fall (0.63 birds/plot/20-min survey) and lowest during the spring (0.16). The most common raptors observed in the study area were red-tailed hawk, Cooper’s hawk, and sharp-shinned hawk. Vultures had the highest use in summer (0.31 birds/plot/20-min survey) and much lower use during all other seasons. Upland gamebirds had much lower use than other bird types recorded, with highest use recorded during spring (0.11 birds/plot/20-min survey). Passerines had the highest use among all bird types across all seasons, with use ranging from 14.13 birds/plot/20-minute survey in the summer to 1.65 in winter.

Levels of bird use varied within the study area by point. For all bird species combined, use was highest at points D, C, and B (13.7, 12.8, and 11.8 birds/20-minute survey, respectively). Bird use at other points ranged from 5.31 to 11.0 birds/20-minute survey. The higher mean use at points D, C, and B was due mostly to relatively high use by passerines at these points (11.1, 11.5, and 11.0 birds/20-minute survey, respectively). Passerine use at other points ranged from 4.15 to 8.94 birds/20-minute survey. Waterfowl use only occurred at point J, with 0.62 birds/20-minute survey. Raptor use was highest at point A (0.56 birds/20-minute survey), and ranged from zero to 0.35 birds/20-minute survey at other points. Vultures were observed at approximately half of the
points (A, B, C, D, E, and H); use ranged from 0.04 birds/20-minute survey at point A to 0.36 at point D.

Survey points were located within evergreen forest habitat in the Whistling Ridge Wind Resource Area. No obvious flyways or concentration areas were observed. No strong association with topographic features within the study area was noted for raptors or other large birds. Although some differences in bird use were detected among survey points, the differences are not large enough to suggest that any portions of the Whistling Ridge Wind Resource Area should be avoided when siting turbines due to very high bird use.

During the study, 523 single or groups of birds totaling 1,449 individuals were observed flying during fixed-point bird use surveys. For all bird species combined, 65.7% of birds were observed flying below the likely zone of risk, 31.3% were within the zone of risk, and 3.0% were observed flying above the zone of risk for typical turbines that could be used in the Whistling Ridge Wind Resource Area. Bird types most often observed flying within the turbine zone of risk were doves/pigeons (58.8%), raptors (58.6%) and vultures (53.6%). Waterfowl were always observed flying above the zone of risk. Upland gamebirds, passerines, and other birds were typically observed flying below the zone of risk.

For all bird species with at least 10 separate groups of flying birds, only six species were observed flying within the zone of risk during more than 50% of observations: red crossbill (90.2%), common raven (55.1%), western bluebird (62.3%), band-tailed pigeon (59.4%), red-tailed hawk (70.0%), and turkey vulture (53.6%). Based on the use (measure of abundance) of the study area by each species and the flight characteristics observed for those species, the red crossbill and common raven had the highest probability of turbine exposure, with exposure indices of 0.29 and 0.23, respectively. The raptor species with the highest exposure index was the red-tailed hawk, which was ranked eleventh of all species, although its exposure index was only 0.05.

The objective of incidental wildlife observations was to provide a record of wildlife seen outside of the standardized surveys. Incidental observations included six bird species and five mammal species. The most abundant bird species recorded incidentally was pine siskin.

Based on fixed-point bird use data collected for the Whistling Ridge Wind Resource Area, mean annual raptor use was 0.28 raptors/plot/20-minute survey. The annual rate was low relative to raptor use at 36 other wind-energy facilities that implemented similar protocols to the present study and had data for three or four different seasons. Mean raptor use in the study area was low compared to these other wind resource areas, ranking twenty-ninth.

A regression analysis of raptor use and raptor collision mortality for 13 new-generation wind-energy facilities where similar methods were used to obtain raptor use estimates showed a significant ($R^2 = 69.9\%$) correlation between raptor use and raptor collision mortality. Due to the low raptor use in comparison to most wind resource areas, using this regression to predict raptor collision mortality the Whistling Ridge Wind Resource Area yielded an estimated fatality rate of zero. However, A 90% prediction interval around this estimate is zero to 0.25 fatalities per megawatt per year.
Based on species composition of the most common raptor fatalities at other western wind-energy facilities and species composition of raptors observed at the Whistling Ridge Wind Resource Area during the surveys, the majority of the fatalities of diurnal raptors will likely consist of red-tailed hawk. Based on the seasonal use estimates, it is expected that risk to raptors would be unequal across seasons, with the lowest risk in spring and winter, and highest risk during the fall.

The data collected during this study suggests that the Whistling Ridge Wind Resource Area does not receive substantial use by waterfowl, and does not appear to be within a major migratory pathway for raptors. In addition, the study area does not appear to provide important stopover habitat for migrant songbirds based on fixed-point bird use surveys. Construction and operation of the wind-energy facility may displace some types of birds.

Some species considered to be sensitive or of conservation concern were observed within the Whistling Ridge Wind Resource Area. During all surveys and incidental observations, five sensitive bird species were observed including 30 Vaux’s swifts, 15 pileated woodpeckers, five northern goshawks, three bald eagles, and two golden eagles. This is a tally that in some cases may represent repeated observations of the same individual.

INTRODUCTION

SDS Lumber has proposed a wind-energy facility in Skamania County, Washington, near the town of White Salmon (Figures 1 and 2). SDS Lumber contracted Western EcoSystems Technology, Inc. (WEST) to conduct surveys and monitor wildlife resources in the Whistling Ridge Wind Resource Area (WRWRA) to estimate the impacts of wind-energy facility construction and operations on wildlife.

The principal objectives of the study were to: 1) provide site specific bird resource and use data that would be useful in evaluating potential impacts from the proposed wind-energy facility; 2) provide information that could be used in project planning and design of the facility to minimize impacts to birds; and 3) recommend further studies or potential mitigation measures, if warranted. The protocols for the baseline studies are similar to those used at other wind-energy facilities across the nation, and follow the guidance of the National Wind Coordinating Collaborative (Anderson et al. 1999). The protocols have been developed based on WEST’s experience studying wildlife at proposed wind-energy facilities throughout the US, and were designed to help predict potential impacts to birds (particularly raptors).

Baseline surveys were conducted from September 11 through November 4, 2004, May 15 through July 14, 2006, and December 4, 2008 through May 29, 2009 at the WRWRA. Surveys were conducted across all four seasons and included fixed-point bird use surveys and incidental wildlife observations. Other baseline data have previously been collected at this site, including bat acoustical surveys, habitat mapping, rare plant surveys, and targeted surveys for species of concern including spotted owl (Strix occidentalis), northern goshawk (Accipiter gentilis), and western gray squirrel (Sciurus griseus). The results of those studies are included in other reports.

In addition to site-specific data, this report presents existing information and results of studies conducted at other wind-energy facilities. The ability to estimate potential bird mortality at the proposed WRWRA is greatly enhanced by operational monitoring data collected at existing wind-energy facilities. For several wind-energy facilities, standardized data on fixed-point surveys were collected in association with standardized post-construction (operational) monitoring, allowing comparisons of bird use with bird mortality. Where possible, comparisons with regional and local studies were made.

STUDY AREA

The proposed wind resource area is in southeast Skamania County, approximately four miles (6.4 kilometers [km]) northwest of White Salmon, Washington (Figure 1). The specific study area is just north of Underwood Mountain and includes Sections 5, 6, 7, & 8, Township 3N, Range 10E. The WRWRA consists of hilltops dominated by coniferous forests with some clearcuts and linear clearings associated with powerline rights-of-way (Figure 2). Elevation of the study area ranges from approximately 1,700 – 2,400 feet (ft; 518 – 732 meters [m]).

Approximately 82.0% of the 1,151-acre (1.8 square mile [mi²]; 4.7 km²) area is composed of evergreen forest (Table 1; Figure 3). Forests in the project area are managed by SDS Lumber for
commercial timber production. The next most common habitat is developed, open space, which comprises 8.5% of the WRWRA. Shrub-scrub habitat comprises 7.1% and grassland areas comprise 1.8% of the WRWRA. All other habitats collectively comprise less than one percent of the WRWRA (Table 1).

**METHODS**

**Fixed-Point Bird Use Surveys**

The objective of the fixed-point bird use surveys was to estimate the seasonal, spatial, and temporal use of the study area by birds, particularly raptors, defined here as kites, accipiters, buteos, harriers, eagles, falcons, and owls. Fixed-point surveys (variable circular plots) were conducted using methods described by Reynolds et al. (1980). The points were selected to survey representative habitats and topography of the study area, while also providing relatively even coverage. All birds seen during each 20-minute (min) fixed-point survey were recorded.

**Bird Use Survey Plots**

Ten points were selected to achieve relatively even coverage of the study area and survey representative habitats and topography within the study area. Six of the points were used for the 2004 and 2006 surveys seasons, with four additional points being added for the 2008/2009 study season (Figure 4). Each survey plot was an 800-m (2,625-ft) radius circle centered on the point.

**Bird Survey Methods**

All species of birds observed during fixed-point surveys were recorded. Observations of large birds beyond the 800 m radius were recorded, but were not included in the statistical analyses; for small birds observations beyond the 100 m (328 ft) radius were excluded. A unique observation number was assigned to each observation.

The date, start and end time of the survey period, and weather information such as temperature, wind speed, wind direction, and cloud cover were recorded for each survey. Species or best possible identification, number of individuals, sex and age class (if possible), distance from plot center when first observed, closest distance, altitude above ground, activity (behavior), and habitat(s) were recorded for each observation. The behavior of each bird observed, and the vegetation type in which or over which the bird occurred, were recorded based on the point of first observation. Approximate flight height and flight direction at first observation were recorded to the nearest 5-m (16-ft) interval.

Locations of raptors, other large birds, and species of concern seen during fixed-point bird use surveys were recorded on field maps by observation number. Flight paths and perched locations were digitized using ArcGIS 9.3. Any comments were recorded in the comments section of the data sheet. Any unusual wildlife observations were recorded on the incidental datasheets.

**Observation Schedule**

Sampling intensity was designed to document bird use and behavior by habitat and season within the study area. Fixed-point surveys were conducted from September 11 through November 4,
2004 (fall migration period), from May 21 through July 14, 2006 (summer breeding season),
from December 4, 2008 through March 15, 2009 (winter), and from March 16 through May 29,
2009 (spring migration period). Surveys were conducted approximately weekly during the
spring, summer and fall, and every other week during the winter. Surveys were conducted during
daylight hours and survey periods were varied to approximately cover all daylight hours during a
season. To the extent practical, each point was surveyed about the same number of times. A total
of 261 20-min fixed-point surveys were conducted at the WRWRA.

Incidental Wildlife Observations

The objective of incidental wildlife observations was to provide a record of wildlife seen outside
of the standardized surveys. All raptors, unusual or unique birds, sensitive species, mammals,
reptiles, and amphibians were recorded in a similar fashion to standardized surveys. The
observation number, date, time, species, number of individuals, sex/age class, distance from
observer, activity, height above ground (for bird species), habitat, and, in the case of sensitive
species, the location was recorded by Universal Transverse Mercator (UTM) or Global
Positioning System (GPS) coordinates.

Statistical Analysis

Quality Assurance and Quality Control
Quality assurance and quality control (QA/QC) measures were implemented at all stages of the
study, including in the field, during data entry and analysis, and report writing. Following field
surveys, observers were responsible for inspecting data forms for completeness, accuracy, and
legibility. A sample of records from an electronic database was compared to the raw data forms
and any errors detected were corrected. Irregular codes or data suspected as questionable were
discussed with the observer and/or project manager. Errors, omissions, or problems identified in
later stages of analysis were traced back to the raw data forms, and appropriate changes in all
steps were made.

Data Compilation and Storage
A Microsoft® ACCESS database was developed to store, organize, and retrieve survey data. Data
were keyed into the electronic database using a pre-defined format to facilitate subsequent
QA/QC and data analysis. All data forms, field notebooks, and electronic data files were retained
for reference.

Fixed-Point Bird Use Surveys
Bird Diversity and Species Richness
Bird diversity was illustrated by the total number of unique species observed. Species lists, with
the number of observations and the number of groups, were generated by season, including all
observations of birds detected regardless of their distance from the observer. Species richness
was calculated as the mean number of species observed per plot per survey (i.e., number of
species/plot/20-min survey). Species diversity and richness were compared between seasons for
fixed-point bird use surveys.
Bird Use, Composition, and Frequency of Occurrence
For the standardized fixed-point bird use estimates, only observations of large birds detected within the 800-m radius plot were used; small birds observations were limited to 100 m. Estimates of mean bird use (i.e., number of birds/plot/20-min survey) were used to compare differences between bird types, seasons, and other wind-energy facilities.

The frequency of occurrence was calculated as the percent of surveys in which a particular species or bird type was observed. Percent composition was calculated as the proportion of the overall mean use for a particular species or bird type. Frequency of occurrence and percent composition provide relative estimates of species exposure to the proposed wind-energy facility. For example, a species may have high use estimates for the area based on just a few observations of large groups; however, the frequency of occurrence will indicate that the species occurs during very few of the surveys and therefore, the species may be less likely affected by the wind resource area.

Bird Flight Height and Behavior
To calculate potential risk to bird species, the first flight height recorded was used to estimate the percentages of birds flying within the likely “zone of risk” (ZOR) for collision with turbine blades of 35 to 130 m (114 to 427 ft) above ground level (AGL), which is the blade height of typical turbines that could be used at the WRWRA.

Bird Exposure Index
A relative index of collision exposure (R) was calculated for bird species observed during the fixed-point bird use surveys using the following formula:

$$R = A \times P_f \times P_t$$

Where A equals mean relative use for species $i$ (large bird observations within 800 m of the observer or 100 m for small birds) averaged across all surveys, $P_f$ equals the proportion of all observations of species $i$ where activity was recorded as flying (an index to the approximate percentage of time species $i$ spends flying during the daylight period), and $P_t$ equals the proportion of all initial flight height observations of species $i$ within the likely ZOR.

Spatial Use
Data were analyzed by comparing use among plots. Mapped flight paths were qualitatively compared to study area features such as topographic features. The objective of mapping observed bird locations and flight paths was to look for areas of concentrated use by raptors and other large birds and/or consistent flight patterns within the study area. This information can be useful in turbine layout design or adjustments of individual turbines for micro-siting.
RESULTS

Surveys were completed at the WRWRA from September 11 through November 4, 2004, May 21 through July 14, 2006 and December 4, 2008 – May 29, 2009. Eighty-eight bird species and five mammal species were identified during surveys completed at the WRWRA. Results of the fixed-point surveys and incidental wildlife observations, and the specific numbers of unique species for each survey type, are discussed in the sections below.

Fixed-Point Bird Use Surveys

Bird Diversity and Species Richness
Eighty-six unique species were observed over the course of all fixed-point bird use surveys, with a mean number 4.51 species/survey (Table 2). More unique species were observed during the spring (67 species), followed by summer (55), fall (39), and winter (16; Table 2). The mean number of species per survey was higher in the summer (10.84 species/survey), compared to spring (4.54), fall (4.02) and winter (1.16; Table 2). A total of 2,663 individual bird observations within 1,407 separate groups were recorded during the fixed-point surveys (Table 3).

Cumulatively, six species (7.0% of all species) composed approximately 43.7% of the observations: dark-eyed junco (Junco hyemalis), American robin (Turdus migratorius), white-crowned sparrow (Zonotrichia leucophrys), yellow-rumped warbler (Dendroica coronata), common raven (Corvus corax), and Steller’s jay (Cyanocitta stelleri). All other species comprised less than 5% of the observations. A total of 76 individual raptors were recorded within the WRWRA, representing 11 species (Table 3).

Bird Use, Composition, and Frequency of Occurrence by Season
Mean bird use, percent composition, and frequency of occurrence for all species and bird types by season were calculated (Table 4). The highest overall bird use occurred in the summer (15.98 birds/plot/20-min survey), followed by fall (14.34), spring (9.13), and winter (1.99). Passerines were the most abundant bird type observed across all seasons.

Waterfowl
Waterfowl were only observed during spring (0.07 birds/plot/20-minute survey; Table 4). The only waterfowl species recorded was Canada goose (Branta canadensis), which consisted of one group of eight individuals observed. Waterfowl comprised 0.8% of overall bird use in spring and were observed during 0.9% of spring surveys.

Raptors
Raptor use was much higher during fall (0.63 birds/plot/20-min survey; Table 4), compared to summer (0.22), winter (0.17) and spring (0.16; Table 4). High raptor use in fall consisted mostly of sharp-shinned hawk (Accipter striatus; 0.13 birds/plot/20-min survey), unidentified buteo (0.13), and Cooper’s hawk (Accipiter cooperii; 0.12). Cooper’s hawk had the highest use of any one raptor species in spring (0.06 birds/plot/20-min survey), red-tailed hawk (Buteo jamaicensis) had the highest use in summer (0.13), and bald eagle (Haliaeetus leucocephalus) had the highest use in winter (0.08), although this was due to observations of only two individual bald eagles. Raptors comprised 8.4% of the overall bird use in winter and 4.4% in fall, compared to 1.8% overall bird use in spring and 1.4% in summer. Raptors were observed during 34.8% of surveys.
in the fall and 22.2% in the summer, compared to 13.3% of the surveys in the winter and 12.9% in the spring.

Vultures
Vulture use was much higher in summer (0.31 birds/plot/20-minute survey; Table 4), than in spring (0.08), fall (0.08), and winter (zero). The only vulture species observed was turkey vulture (Cathartes aura). Vultures comprised 1.9% of overall bird use during summer surveys, 0.9% during spring surveys, and 0.5% during fall surveys. Vultures were observed during 11.1% of summer surveys, compared to 6.7% of spring surveys and 5.9% of fall surveys.

Upland Gamebirds
Upland gamebirds had relatively low use in spring, summer, and fall (0.11 birds/plot/20-minute survey, 0.02, and 0.02, respectively; Table 4). Only three upland gamebird species were observed within the WRWRA, including wild turkey (Meleagris gallopavo), sooty grouse (Dendragapus fuliginosus), and ruffed grouse (Bonasa umbellus). Upland gamebirds comprised 1.2% of overall bird use during spring surveys and only 0.1% during both summer and fall surveys. Upland gamebirds were observed during 10.1% of surveys in the spring compared to 2.2% of summer surveys and 1.9% of fall surveys.

Passerines
Passerines had the highest use of any bird type during all four seasons (Table 4). Passerine use was highest in summer (14.13 birds/plot/20-minute survey) and fall (12.53), and lower during spring (7.88) and winter (1.69). Passerine use varied by season. Passerines with the highest use by season were American robin in spring (1.31 birds/plot/20-minute survey), white-crowned sparrow in summer (2.07), dark-eyed junco in fall (2.19), and common raven in winter (0.69). Passerines comprised greater than 80% of overall bird use during all seasons. Passerines were observed during 90% or more of the surveys during spring, summer, and fall surveys, and 58.3% of surveys in winter.

Bird Flight Height and Behavior
Flight height characteristics were estimated for both bird types and bird species (Tables 5 and 6). During the study, 523 single birds or groups totaling 1,449 individuals were observed flying during fixed-point bird use surveys (Table 5). Overall, 31.3% of birds observed flying were recorded within the ZOR for collision with turbine blades of 35 to 130 m (114 to 427 ft) AGL, 65.7% were below the ZOR, and 3.0% were flying above the ZOR (Table 5). More than half (58.6%) of flying raptors were observed flying within the ZOR, 15.5% were below the ZOR, and only 25.9% were above the ZOR. Raptor subtypes that were observed within the ZOR most often were falcons (100%), accipiters (65.2%), and eagles (60.0%). Doves/pigeons had the highest percentage of flying birds within the ZOR (58.8%) followed by raptors (58.6%) and vultures (53.6%). Upland gamebirds, passerines, and other birds were typically observed flying below the ZOR (Table 5).

Six species had at least 10 groups observed flying and were observed flying within the ZOR during at least 50% of observations, including red crossbill (Loxia curvirostra; 90.2%), common raven (Corvus corax; 55.1%), western bluebird (Sialia mexicana; 62.3%), band-tailed pigeon (Columba fasciata; 59.4%), red-tailed hawk (70.0%) and turkey vulture (53.6%; Table 6). Ten
species were always seen flying within the likely ZOR; however, these were based on fewer than five observations.

**Bird Exposure Index**
A relative exposure index was calculated for each species (Table 6). This index is only based on initial flight height observations and relative abundance (defined as the use estimate) and does not account for other possible collision risk factors such as foraging or courtship behavior. Red crossbill (0.29) and common raven (0.23) had exposure indices higher than any other species. Red-tailed hawk had the highest exposure index of any raptor species (0.05); all other raptor species had an exposure index of 0.02 or less (Table 6).

**Spatial Use**
For all bird species combined, use was highest at points D, C, and B (13.7, 12.8 and 11.8 birds/20-min survey, respectively). Bird use at other points ranged from 5.31 to 11.0 birds/20-min survey (Figure 5). The higher mean use estimates for points D, C, and B were largely due to higher passerine use at these points (11.1, 11.5, and 11.0 birds/20-min survey, respectively). Passerine use at the other points ranged from 4.15 to 8.94 birds/20-min survey. Waterfowl use only occurred at point J with 0.62 birds/20-min survey. Raptor use was highest at point A (0.56 birds/20-min survey), and ranged from zero to 0.35 birds/20-min survey at other points. Vultures were observed at approximately half of the points (A, B, C, D, E, and H); use ranged from 0.04 birds/20-min survey at point A to 0.36 at point D. Upland gamebird use was highest at point G (0.17 birds/20-min survey), and ranged from zero to 0.09 birds/20-min survey at other points.

Flight paths for waterbirds, waterfowl, shorebirds, raptors, and vultures were digitized and mapped (Figures 6a-d). No obvious flyways or concentration areas were observed for any species. The available data do not indicate that any portions of the study area warrant being excluded from development due to very high bird use.

**Incidental Wildlife Observations**
There were six bird species observed incidentally, totaling 23 birds within eight separate groups during the study (Table 7). Five mammal species were also observed incidentally at the WRWRA.

**Bird Observations**
The most abundant bird species recorded as an incidental wildlife observation was pine siskin (*Carduelis pinus*; nine individuals). Two species, osprey (*Pandion haliaetus*) and common poorwill (*Phalaenoptilus nuttallii*), were only seen incidentally at the WRWRA. Canada goose, red-tailed hawk, and ruffed grouse (*Bonasa umbellus*) were also observed incidentally.

**Mammal Observations**
A total of five mammal species including 43 mule deer (*Odocoileus hemionus*), nine black-tailed deer (*Odocoileus hemionus columbianus*), three elk (*Cervus elephus*), one Douglas squirrel (*Tamiasciurus douglasii*), and one gray squirrel (*Sciurus* sp.) were observed incidentally during the fixed-point surveys at the WRWRA (Table 8). The gray squirrel was only observed for a
brief period and therefore it could not be positively identified as being either a state threatened western gray squirrel or an eastern gray squirrel (*Sciurus carolinensis*).

**DISCUSSION AND IMPACT ASSESSMENT**

**Bird Impacts**

**Direct Effects**

The most probable direct impact to birds from wind-energy facilities is direct mortality or injury due to collisions with turbines or guy wires of meteorological (met) towers. Collisions may occur with resident birds foraging and flying within the study area or with migrant birds seasonally moving through the study area. Project construction could affect birds through loss of habitat, or potential fatalities from construction equipment. Impacts from the decommissioning of the facility are anticipated to be similar to construction in terms of noise, disturbance, and equipment. Potential mortality from construction equipment is expected to be very low. Equipment used in wind-energy facility construction generally moves at slow rates or is stationary for long periods (e.g., cranes). The risk of direct mortality to birds from construction is most likely potential destruction of a nest during initial site clearing if conducted during the nesting season.

Substantial data on bird mortality at wind-energy facilities are available from studies in California and throughout the West and Midwest. Of 841 bird fatalities reported from California studies (more than 70% from the Altamont Pass facility in California), about 39% were diurnal raptors, about 19% were passerines (excluding house sparrows [*Passer domesticus*] and European starlings [*Sturnus vulgaris*]), and about 12% were owls. Non-protected birds including house sparrows, European starlings, and rock pigeons (*Columba livia*) comprised about 15% of the fatalities. Other bird types generally made up less than 10% of the fatalities (Erickson et al. 2002b). During 12 fatality monitoring studies conducted outside of California, diurnal raptor fatalities comprised about 2% of the wind-energy facility-related fatalities and raptor mortality averaged 0.03/turbine/year. Passerines (excluding house sparrows and European starlings) were the most common collision victims, comprising about 82% of the 225 fatalities documented. For all bird species combined, estimates of the number of bird fatalities per turbine per year from individual studies ranged from zero at the Searsburg wind-energy facility in Vermont (Kerlinger 1997) and the Algona facility in Iowa (Demastes and Trainer 2000), to 7.7 at the Buffalo Mountain facility in Tennessee (Nicholson 2003). Using mortality data from a 10-year period from wind-energy facilities throughout the entire United States, the average number of bird collision fatalities is 3.1 per megawatt (MW) per year, or 2.3 per turbine per year (NWCC 2004).

**Raptor Use and Exposure Risk**

The annual mean raptor use at the WRWRA (0.28 raptors/plot/20-min survey) was compared with other wind-energy facilities that implemented similar protocols and had data for three or four seasons. Similar studies were conducted at 36 other wind-energy facilities. The annual mean raptor use at these wind-energy facilities ranged from 0.09 to 2.34 raptors/plot/20-min survey (Figure 7). Based on the results from these wind-energy facilities, a ranking of seasonal raptor mean use was developed as: low (0 – 0.5 raptors/plot/20-min survey); low to moderate (0.5 –
1.0); moderate (1.0 – 2.0); high (2.0 – 3.0); and very high (> 3.0). Under this ranking, mean raptor use (number of raptors divided by the number of 800 m plots and the total number of surveys) at the WRWRA is considered to be low. Compared to the other wind-energy facilities, the WRWRA ranked twenty-ninth (Figure 7).

Although high numbers of raptor fatalities have been documented at some wind-energy facilities (e.g. Altamont Pass), a review of studies at wind-energy facilities across the United States reported that only 3.2% of casualties were raptors (Erickson et al. 2001a). Indeed, although raptors occur in most areas with the potential for wind-energy development, individual species appear to differ from one another in their susceptibility to collision (NRC 2007). Results from Altamont Pass in California suggest that mortality for some species is not necessarily related to abundance (Orloff and Flannery 1992). American kestrels (*Falco sparverius*), red-tailed hawks, and golden eagles (*Aquila chrysaetos*) were killed more often than predicted based on abundance. Thus far, only three northern harrier (*Circus cyaneus*) fatalities at existing wind energy facilities have been reported in publicly available documents, despite the fact they are commonly observed during point counts at these facilities (Erickson et al. 2001a; Whitfield and Madders 2006). Because northern harriers often forage close to the ground, risk of collision with turbine blades is considered low for this species. Relative use by American kestrels at the High Winds facility was almost six times the use of American kestrels at the Altamont Pass facility (Kerlinger 2005). It is likely that many factors, in addition to abundance, are important in predicting raptor mortality.

An exposure index analysis may also provide insight into what species has a higher likelihood of turbine casualties. The index considers relative probability of exposure based on abundance, proportion of daily activity spent flying, and proportion of flight height of each species within the ZOR for turbines likely to be used at the wind-energy facility. For the WRWRA, the raptor species with the highest exposure index was the red-tailed hawk, which was ranked eleventh of all species (Table 6). The exposure index analysis is based on observations of birds during the daylight period and does not take into consideration flight behavior (e.g., during foraging or courtship) or abundance of nocturnal migrants. It also does not take into consideration habitat selection, the ability to detect and avoid turbines, and other factors that may vary among species and influence likelihood for turbine collision. For these reasons, the actual risk for some species may be lower or higher than indicated by this index.

A regression analysis of raptor use and mortality for 13 new-generation wind-energy facilities, where similar methods were used to estimate raptor use and mortality, found that there was a significant correlation between use and mortality ($R^2 = 69.9\%$; Figure 8). Using this regression to predict raptor collision mortality at the WRWRA, based on an adjusted mean raptor use of 0.28 raptors/20-min survey, yields an estimated fatality rate of zero due to the low raptor use observed. A 90% prediction interval around this estimate is zero to 0.25 fatalities/MW/year. Based on the relative abundance of red-tailed hawks, Cooper’s hawks, and sharp-shinned hawks, there is higher potential for fatalities of these three species compared to other species.

**Non-Raptor Use and Exposure Risk**

Mean overall bird use at the WRWRA was 9.3 birds/800-m radius plot/20-minute survey. Mean overall bird use for 24 other WRAs in the Pacific Northwest has ranged from 5-23.6.
WRWRA ranks 19th compared to these 24 other WRA (Figure 9). To date, no relationships have been observed between overall use by bird types other than raptors, and fatality rates of those bird types at wind-energy facilities. However, the overall avian use at the WRWRA is low compared to most other WRAs in the Pacific Northwest and therefore high levels of avian mortality would not be expected.

Most bird species in the US are protected by the Migratory Bird Treaty Act (MBTA 1918). Passerines (primarily perching birds) have been the most abundant bird fatality at wind energy facilities outside California (Erickson et al. 2001a, 2002b), often comprising more than 80% of the bird fatalities. Both migrant and resident passerine fatalities have been observed. Given that passerines made up a large proportion of the birds observed during the baseline study, passerines would be expected to make up the largest proportion of fatalities at the WRWRA. Exposure indices based on observations within 100 m indicate that red crossbill is the most likely passerine to be exposed to collision from wind turbines at the WRWRA. Other passerine species likely most at risk based on abundance and flight behavior would include common raven, American robin, western bluebird, tree swallow (Tachycineta bicolor), evening grosbeak (Coccothraustes vespertinus), Vaux’s swift (Chaetura vauxi), and American goldfinch (Carduelis tristis; Table 6b). Other non-raptor species with high exposure indices include turkey vulture and band-tailed pigeon. Most non-raptors had relatively low exposure indices due to the majority of individuals flying below the likely zone of risk. Due to the low exposure risks at WRWRA, it is unlikely that non-raptor populations will be adversely affected by direct mortality from the operation of the wind-energy facility.

The only waterfowl species observed in the WRWRA was a single group of eight Canada goose recorded during spring fixed-point bird use surveys, and another group of six individuals were observed incidentally. Wind-energy facilities with year-round use by water dependent species have shown the highest mortality, although the levels of waterfowl/waterbird/shorebird mortality appear insignificant compared to the use of the facilities by these groups. Of 1,033 bird carcasses collected at US wind-energy facilities, waterbirds comprised about 2%, waterfowl comprised about 3%, and shorebirds comprised less than 1% (Erickson et al. 2002b). At the Klondike, Oregon wind-energy facility, only two Canada goose fatalities were documented (Johnson et al. 2003) even though 43 groups totaling 4845 individual Canada geese were observed during pre-construction surveys (Johnson et al. 2002a). The recently constructed Top of Iowa wind-energy facility is located in cropland between three Wildlife Management Areas (WMAs) with historically high bird use, including migrant and resident waterfowl. During a recent study, approximately one million goose-use days and 120,000 duck-use days were recorded in the WMAs during the fall and early winter, and no waterfowl fatalities were documented during concurrent and standardized wind-energy facility fatality studies (Jain 2005). Similar findings were observed at the Buffalo Ridge wind-energy facility in southwestern Minnesota, which is located in an area with relatively high waterfowl/waterbird use and some shorebird use. Snow geese (Chen caerulescens), Canada geese, and mallards (Anas platyrhynchos) were the most common waterfowl observed. Three of the 55 fatalities observed during the fatality monitoring studies were waterfowl, including two mallards and one blue-winged teal (Anas discors). Two American coots (Fulica americana), one grebe, and one shorebird fatality were also found (Johnson et al. 2002b). Based on available evidence, waterfowl do not seem especially vulnerable to turbine collisions and significant impacts are not likely.
Sensitive Species Use and Exposure Risk

All sensitive species observed at the WRWRA are summarized in Table 8. No federal-listed species were observed during the study (Table 3). One gray squirrel was observed as an incidental observation. However, the gray squirrel was only observed for a brief period and therefore it could not be positively identified as being either a state threatened western gray squirrel or an eastern gray squirrel. One state sensitive species, bald eagle, was observed during fixed-point surveys at the WRWRA (two observations; Table 2). Four state candidate species, Vaux’s swift, pileated woodpecker (*Dryocopus pileatus*), northern goshawk, and golden eagle, were observed during fixed point surveys (Table 8). The bald eagle and golden eagle are also legally protected under the Bald and Golden Eagle Protection Act (BGEPA 1940), while the others are protected under the Migratory Bird Treaty Act (MBTA 1918).

Use of the WRWRA by bald eagle, northern goshawk, and golden eagle was very low, and significant impacts are not expected. Vaux’s swifts were fairly common and were commonly observed flying at turbine rotor-swept heights; therefore, some turbine mortality may occur for these species over the life of the facility. These collisions would likely be rare occurrences and it is unlikely the WRWRA would have any negative impacts on population levels in and near the study area. Based on seasonality of the observations, the Vaux’s swifts appear to be migrants through the WRWRA rather than local breeding residents.

Indirect Effects

The presence of wind turbines may alter the landscape so that wildlife use patterns are affected, displacing wildlife away from the project facilities and suitable habitat. Some studies from wind-energy facilities in Europe consider displacement effects to have a greater impact on birds than collision mortality (Gil et al. 1996). The greatest concern with displacement impacts for wind-energy facilities in the US has been where these facilities have been constructed in grassland or other native habitats (Leddy et al. 1999; Mabey and Paul 2007). Although Crockford (1992) suggests that disturbance appears to impact feeding, resting, and migrating birds, rather than breeding birds, results from studies at the Stateline wind-energy facility in Washington and Oregon (Erickson et al. 2004) and the Buffalo Ridge wind-energy facility in Minnesota (Johnson et al. 2000a) suggest that breeding birds are also affected by wind-facility operations.

Raptor Displacement

In addition to possible direct effects on raptors within the study area (discussed above), indirect effects caused by disturbance-type impacts, such as construction activity near an active nest or primary foraging area, also have a potential impact on raptor species. Birds displaced from wind-energy facilities might move to areas with fewer disturbances, but with lower quality habitat, with an overall effect of reducing breeding success. Most studies on raptor displacement at wind-energy facilities, however, indicate effects to be negligible (Howell and Noone 1992; Johnson et al. 2000a, 2003; Madders and Whitfield 2006). Notable exceptions to this include a study in Scotland that described territorial golden eagles avoiding the entire wind-energy facility area, except when intercepting non-territorial birds (Walker et al. 2005). A study at the Buffalo Ridge wind-energy facility in Minnesota found evidence of northern harriers avoiding turbines on both a small scale (< 100 m from turbines) and a larger scale in the year following construction (Johnson et al. 2000a). Two years following construction, however, no large-scale displacement of northern harriers was detected.
The only published report of avoidance of wind turbines by nesting raptors occurred at Buffalo Ridge, Minnesota, where raptor nest density on 101 mi² (262 km²) of land surrounding a wind-energy facility was 5.94 nests/39 mi² (5.94 nests/101 km²), yet no nests were present in the 12 mi² (31 km²) facility itself, even though habitat was similar (Usgaard et al. 1997). However, this analysis assumes that raptor nests are uniformly distributed across the landscape, an unlikely event, and even though no nests were found, only two nests would be expected for an area 12 mi² in size if the nests were distributed uniformly. At a wind-energy facility in eastern Washington, based on extensive monitoring using helicopter flights and ground observations, raptors still nested in the study area at approximately the same levels after construction, and several nests were located within 0.5 miles (0.8 km) of turbines (Erickson et al. 2004). At the Foote Creek Rim Wind-Energy Facility in southern Wyoming, one pair of red-tailed hawks nested within 0.3 miles (0.5 km) of the turbine strings, and seven red-tailed hawk nests, one great horned owl (*Bubo virginianus*) nest, and one golden eagle nest located within one mile (1.6 km) of the wind-energy facility successfully fledged young (Johnson et al. 2000b). The golden eagle pair successfully nested 0.5 mile from the facility for three different years after it became operational. A Swainson’s hawk (*Buteo swainsoni*) also nested within 0.25 mile (0.4 km) of a turbine string at the Klondike I wind-energy facility in Oregon after the facility was operational (Johnson et al. 2003). These observations suggest that there will be limited nesting displacement of raptors at the WRWRA.

**Displacement of Non-Raptor Bird Species**

Studies concerning displacement of non-raptor species have concentrated on grassland passerines and waterfowl/waterbirds (Winkelman 1990; Larsen and Madsen 2000; Mabey and Paul 2007). Wind-energy facility construction appears to cause small-scale local displacement of grassland passerines and is likely due to the birds avoiding turbine noise and maintenance activities. Construction also reduces habitat effectiveness because of the presence of access roads and large gravel pads surrounding turbines (Leddy 1996; Johnson et al. 2000a). Leddy et al. (1999) surveyed bird densities in Conservation Reserve Program (CRP) grasslands at the Buffalo Ridge wind-energy facility in Minnesota, and found mean densities of 10 grassland bird species were four times higher at areas located 180 m (591 ft) from turbines than they were at grasslands nearer turbines. Johnson et al. (2000a) found reduced use of habitat by seven of 22 grassland-breeding birds following construction of the Buffalo Ridge wind energy facility in Minnesota. Results from the Stateline wind-energy facility in Oregon and Washington (Erickson et al. 2004), and the Combine Hills wind-energy facility in Oregon (Young et al. 2005), suggest a relatively small impact of the wind-energy facilities on grassland nesting passerines. Transect surveys conducted prior to and after construction of the wind-energy facilities found that grassland passerine use was significantly reduced within approximately 50 m (164 ft) of turbine strings, but areas further away from turbine strings did not have reduced bird use.

Displacement effects of wind-energy facilities on waterfowl and shorebirds appear to be mixed. Studies from the Netherlands and Denmark suggest that densities of these types of species near turbines were lower compared to densities in similar habitats away from turbines (Winkelman 1990; Pedersen and Poulsen 1991). However, a study from a facility in England, found no effect of wind turbines on populations of cormorant (*Phalacrorax xarbo*), purple sandpipers (*Calidris maritima*), eiders (*Somateria mollissima*), or gulls, although the cormorants were temporarily displaced during construction (Lawrence et al. 2007). At the Buffalo Ridge wind-energy facility
in Minnesota, the abundance of several bird types, including shorebirds and waterfowl, were found to be significantly lower at survey plots with turbines than at reference plots without turbines (Johnson et al. 2000a). The report concluded that the area of reduced use was limited primarily to those areas within 100 m of the turbines. Disturbance tends to be greatest for migrating birds while feeding and resting (Crockford 1992; NRC 2007). The only waterfowl/waterbirds use at the WRWRA included one group of eight Canada goose observed during spring fixed-point bird use surveys and one group of six individuals during incidental observations. Based on the minimal presence of waterfowl/waterbird species, impacts should be negligible.

A study conducted in England to assess displacement of wintering farmland birds by wind turbines located in an agricultural landscape found that only common (ring-necked) pheasants (Phasianus colchicus) apparently avoided turbines. The other species/bird groups examined, including granivores, red-legged partridge (Alectoris rufa), Eurasian skylark (Alauda arvensis) and corvids, showed no displacement from wind turbines. In fact, Eurasian skylarks and corvids showed increased use of areas close to turbines, possibly due to increased food resources associated with disturbed areas (Devereux et al. 2008).

No studies have been conducted to assess displacement effects of birds in western coniferous forest. It is likely that some displacement may occur similar to that observed in other habitat types.

CONCLUSIONS AND RECOMMENDATIONS

Based on data collected during this study, raptor and all bird use of the WRWRA is generally lower than most wind resource areas evaluated throughout the western and Midwestern U.S. using similar methods. Based on the results of the studies to date, bird mortality at the WRWRA would likely be similar or lower than that documented at other wind-energy facilities located in the western and Midwestern United States where bird collision mortality has been relatively low.

Based on research conducted at wind-energy facilities throughout the US, raptor use at the WRWRA is generally lower than use levels recorded at other wind-energy facilities. Raptor fatality rates are expected to be within the range of fatality rates observed at other facilities where raptor use levels are lower. To date, no relationships have been observed between overall use by other bird types, and fatality rates of those bird types at wind-energy facilities. However, the flight characteristics and foraging habits of some species may result in increased exposure for these species at the WRWRA. The surveys conducted for this proposed wind resource area also do not address the impacts of the proposed facility to nocturnal migrants, such as passerines. To date, overall fatality rates for birds (including nocturnal migrants) at wind-energy facilities have been relatively low and consistent in the West. As more research is conducted at facilities in the West, more information regarding the potential direct impacts of wind-energy facilities to bird species will be obtained.

The proposed wind-energy facility contains minimal habitat diversity; approximately 82% of the WRWRA contains forested habitat, while the remaining areas are comprised of developed open

Western EcoSystems Technology, Inc. 13 August 7, 2009
space, scrub-shrub, and grasslands (Table 1, Figure 3). Some species considered to be sensitive or of conservation concern were observed within the WRWRA. Some potential exists for wind turbines to displace birds within forested habitats. Research concerning displacement impacts to songbirds, waterfowl and waterbirds and wind-energy facilities is limited, but some studies show the potential for small scale (180 m or less) displacement, while impacts to densities of birds at larger scales has not been shown.

Turnstone Environmental Consultants, Inc.
October 2004
INTRODUCTION

PPM Energy, Inc. (PPM) with guidance from CH2MILL retained the services of Turnstone Environmental Consultants Inc. (TECI) to perform wildlife studies as part of the proposed Saddleback Wind Energy Project. PPM performs extensive environmental impact studies evaluating existing land use as well as impacts on birds, bats, rare plants and waterways to determine whether a site is suitable for wind power generation. PPM is committed to minimize impacts on natural resources by selecting wind development sites that are designed to be as environmentally friendly to the land and communities as it is to the air. Wind energy, the least-cost renewable technology, is a remarkable, sustainable resource for electricity generation. Wind power is the fastest growing area of power generation in the world. PPM Energy Inc. is leading the market to make this green power source as dependable and affordable as any other form of energy.

TECI performed surveys for the northern spotted owl (Strix occidentalis caurina), northern goshawk (Accipiter gentilis), and western gray squirrel (Sciurus griseus) in consultation with CH2MILL for the Saddleback Wind Energy Project. Throughout Oregon and the Pacific Northwest, TECI specializes in natural resource inventory, assessment and analysis. TECI is committed to providing the highest quality work product for our clients in the field of natural resource management - assisting land owners and managers in the decision making process. TECI is an Oregon based company founded in 1995 with offices in Portland and Corvallis. The TECI staff has extensive experience in a wide variety of wildlife and fisheries survey, inventory, rehabilitation and research projects, and has worked with federal, state and tribal governments as well as private landowners.

Northern Spotted Owl

The northern spotted owl (Strix occidentalis caurina) was listed in 1990 as a “threatened” species under the Endangered Species Act (ESA) of 1973 by both the U.S. Fish and Wildlife Service and the State of Washington. Both federal and state agencies determined that the northern spotted owl was likely to become an endangered species in the foreseeable future throughout all or a significant portion of its existing range. The physiographic range and habitat requirements of the northern spotted owl are located within the forestlands of the PPM Saddleback Wind Energy Project. As part of the process to avoid a “take” of any northern spotted owls under the ESA, PPM with guidance from CH2MILL had surveys completed for northern spotted owls in and around suitable habitat prior to any management activity.

Suitable Habitat

In Washington, northern spotted owls inhabit the Eastern and Western Cascades, Western Lowlands and Olympic Peninsula Provinces. Within these regions, the northern spotted owl requires a multitude of habitat types for nesting, roosting, foraging and dispersal. The species seeks forests composed of a multi-layered, multi-species canopy with a high incidence of large trees with appropriate structure for nesting and roosting. Northern spotted owls generally rely on large home ranges and use large tracts of land containing older forest to meet their biological needs. Fragmented habitats may be used for dispersal and foraging. Spotted owls nest primarily in stick nests of northern goshawks, on clumps of mistletoe, in large tree cavities, on broken tops of large trees, on large branches or cavities in banks and rock faces.
Survey Locations
With the guidance of CH2MILL, TECI conducted northern spotted owl surveys within and adjacent to properties managed by SDS Lumber Co. (SDS) and other willing adjacent landowners. Surveys were conducted in suitable habitat in four core project sections located in Township 3N, Range 10E, Sections 5, 6, 7, and 8. The provincial home range radius surrounding the core area appropriate for this physiographic location is 1.8 miles. Surveys were conducted in suitable habitat in the provincial home range radius in Township 3N, Range 10E, Sections 4, 9,10,17,19,20,21; Township 4N, Range 10E, Sections 28,29,30,31,32,33,34; Township 4N, Range 09E, Sections 25,35,36; Township 3N, Range 09E, Sections 1,2,11,12,13,24.

Survey Methods
Potential habitat was surveyed in 2003-2004 in accordance to the 1992 Revised Version of “Protocol for Surveying Proposed Management Activities That May Impact Northern Spotted Owls” endorsed by the U.S. Fish and Wildlife Service. TECI used the 1-year survey methodology, surveying the project area six times from March 24, 2003 to July 23, 2003 and used the 2-year survey methodology, surveying three times from March 31, 2004 to August 18, 2004. TECI surveyed again in 2004 to lengthen the time period in which management activities could occur in the area of potential impact before northern spotted owl surveys would again be required. TECI collected information on northern spotted owl historical sites and potential owl activity in proposed areas of future management projects. CH2MILL and the Washington Department of Fish and Wildlife (WDFW) will use this survey information to assess occupancy and reproductive status of the northern spotted owl within areas of proposed management activities.

TECI biologists analyzed the project area using topographic maps and aerial photography to determine suitable habitat and potential spot calling station placement. Spot calling stations were place along ridges and away from streams to maximize coverage by enhancing sound transmission. Spot calling stations and survey routes were situated to achieve complete coverage of the area, preferably with coverage from more than one calling point. Stations were spaced approximately 1/4 to 1/2 mile apart where access was permitted and suitable habitat warranted. Most spot calling stations were surveyed at night when owls are more active and are thought to be more responsive to standard survey techniques (USDI 1992b). Some stations were called during daylight in remote/difficult to access areas. TECI biologist used ten-minute calling periods for each station. Voice hooting and “hoot flutes” were used to broadcast both male and female spotted owl vocalizations that included four note contact calls and agitated calls. TECI conducted surveys between March 15 and August 31 as stipulated by the protocol.

During the 2003/2004 survey season, TECI recorded all owl species responses in the field from each calling station during each site visit on the field data forms. Barred owls have been thought to displace spotted owls; therefore, special attention was given to any responses recorded in the survey area. Barred owl responses were recorded on the field data and mapped (locations are approximate) to provide additional information to help direct any future management decisions (map 6).

Survey Results
TECI conducted northern spotted owl surveys in and adjacent to SDS properties (maps 1-6). During the 2003 northern spotted owl survey season, TECI completed six site visits to protocol (survey dates are found in Table 2). During the 2004 northern spotted owl survey season, three site visits were completed to protocol. Calling stations were strategically set throughout the proposed area of impact with the inclusion of a 1.8-mile radius around the potential area of future management activities.

- In 2003, during the first two site visits, 64 calling stations were originally set and called. During the remaining four site visits, 63 calling stations were surveyed after consultation with the SDS foresters. (One calling station, B-17, was dropped due to a logging operation.) No northern spotted owl responses were recorded during any of the six site visits for 2003. Nine barred owl responses were recorded during the six site visits (map 6).

- In 2004, 64 calling stations were surveyed during the first site visits. During the remaining two site visits, 62 calling stations were surveyed. (Two calling stations were dropped, B-17 and B-19, due to logging operations.) No northern spotted owl responses were recorded during any of the three site visits for 2004. Three barred owl responses were recorded during the three site visits (map 6).

Two historical owl sites were surveyed to obtain information on the presence of northern spotted owls. TECI combined efforts with National Council for Air and Stream Improvement (NCASI) to investigate the status of northern spotted owls at the Moss Creek and Mill Creek sites.

- In 2003, three-day site visits were performed at the historical nest sites of both Moss Creek and Mill Creek with no northern spotted owl observations or responses. TECI continued to call the two historical nest sites in the evening six more times with no northern spotted owl responses. On May 5, 2003, a NCASI surveyor observed an unidentified Strix owl at dusk (barred or northern spotted owl observation). Five surveys were conducted after the Strix observation with no visual conformation or audible responses to confirm the Strix presence. Eight of the nine barred owl responses for 2003 occurred within 1.5 miles of the Mill Creek historical nest site. No barred owls were observed while conducting the Moss Creek nest status day surveys.

- In 2004, three site visits were performed at the historical nest sites of both Moss Creek and Mill Creek with no northern spotted owl observations or responses. Two of the three barred owl responses for 2004 occurred within 1.5 miles of the Mill Creek historical nest site. One of the three barred owl responses for 2004 occurred within 1.5 miles of the Moss Creek historical nest site.

With the consistent barred owl responses during the evening surveys so close to the historical nest sites, it appears that barred owls are using areas once inhabited by northern spotted owls.

The following tables summarize all survey site results for the project area including the 1.8 mile radius around the proposed project area of future management activities. Table 1 depicts the Survey Summary Results for 2003 - 2004 and Table 2 depicts the historical site information for Moss Creek and Mill Creek.

### Northern Goshawk

The northern goshawk (*Accipiter gentilis*) is categorized as a “species of concern” by the U.S. Fish and Wildlife Service and as a “listing candidate” for sensitive, threatened or endangered species by the State of Washington Department of Fish and Wildlife. The physiographic range and habitat requirements of the northern goshawk are located within the forestlands of the PPM Saddleback Wind Energy Project.

**Suitable Habitat**

Goshawks inhabit a wide variety of forest habitats, including true fir (red fir, white fir, and subalpine fir), mixed conifer, lodgepole pine, ponderosa pine, Jeffrey pine, montane riparian deciduous forest and Douglas fir. They are occasionally found nesting in coast redwood and mixed hardwood forest. Goshawk nest sites tend to be associated with patches of relatively larger, denser forest than the surrounding landscape; however, home ranges often consist of a wide range of forest age classes and conditions. Numerous habitat studies and modeling efforts have found nest sites to be associated with similar factors including proximity to water or meadow habitat, forest openings, level terrain or “benches” of gentle slope, northerly aspects and patches of larger, denser trees, but these factors...
vary widely. (USDI 2002).

Survey Locations
With the guidance of CH2MHILL, TECI conducted northern goshawk surveys within and adjacent to properties managed by SDS and other willing adjacent landowners. Surveys were conducted in suitable habitat in four core project sections located in Township 4N, Range 10E, Sections 5, 6, 7, and 8. The provincial home range radius surrounding the core area appropriate for this physiographic location is 0.5 miles. Surveys were conducted in suitable habitat in the provincial home range radius in Township 3N, Range 09E, Sections 13, 24; Township 3N, Range 10E, Section 18.

Survey Methods
Potential habitat was surveyed in accordance to the 2002 “Survey Methodology for Northern Goshawks in the Pacific Southwest Region” developed by the United States Forest Service (USFS 2002). TECI biologists analyzed the project area using topographic maps and aerial photography to determine suitable habitat and potential station placement. TECI biologists established stations in the field at approximately 350 yards (0.2 miles) apart on roads and trails in suitable habitat within 0.5 miles of the proposed wind turbine location. Call stations were established to achieve complete coverage in all portions of the project area. At each station, calls were broadcast for 10 seconds; TECI biologists would then stop and listen for 30 seconds. This sequence was repeated four times at each station, broadcasting in four cardinal directions. Surveys started ½ hour before sunrise continued through the day and concluded ½ hour before sunset as specified by the protocol. During the 2004 survey season, TECI recorded all raptor species responses from every calling station during each site visit on the field data forms.

Survey Results
Turnstone Environmental Consultants Inc. conducted northern goshawk surveys in and adjacent to SDS properties (map 7), all calling stations were strategically set throughout the proposed area of impact with the inclusion of a 0.5-mile radius around the potential area of future management activities. TECI completed two site visits to protocol during the 2004 northern goshawk survey season (survey dates are found in Table 6). One hundred eighty-five calling stations were surveyed for both protocol visits. No northern goshawk responses were recorded during any of the two site visits.

Western Gray Squirrel

The western gray squirrel (*Sciurus griseus*) is listed as a “threatened” species by the Washington State Department of Fish and Wildlife (WDFW). The physiographic range and habitat requirements of the western gray squirrel are located within the forestlands of the PPM Saddleback Wind Energy Project.

Suitable Habitat

Western gray squirrels are arboreal (adapted for living in trees) and, although they forage on the ground, they rarely stray far from trees. They use tree canopies for escape, cover and nesting. Western gray squirrels can move rapidly and cover long distances among tree canopies when canopy conditions permit. A contiguous tree canopy that allows arboreal travel for at least 198 feet (60 meters) around the nest is an important feature of western gray squirrel habitat (Ryan and Carey 1995a). Western gray squirrels are most active in August and September, when they are collecting and storing food for winter, and they are less visible in June and July (Ryan and Carey 1995a).

Currently in Washington, the western gray squirrel distribution has been reduced to three geographically isolated western gray squirrel populations in Washington: the "Puget Trough" population, now centered in Thurston and Pierce counties in the Puget Sound region; the "South Cascades" population in extreme eastern Skamania County and Klickitat and Yakima counties; and the "North Cascades" population in Chelan and Okanogan counties.
In Washington, and elsewhere within the subspecies' range, the principal food is acorns, although the seeds of Douglas-fir and other conifers are also eaten (Dalquest 1948). While pine nuts and acorns are considered essential foods for storing body fat and conditioning western gray squirrels for winter, green vegetation, seeds and nuts of trees and shrubs, fleshy fruits, mushrooms and other foods are also consumed. Hypogeous fungi (underground fungi such as truffles) comprise a large portion of the western gray squirrel diet (WDW 1993; Carraway and Verts 1994; Ryan and Carey 1995a).

Survey Locations
With the guidance of CH2MILL, TECI conducted general western gray squirrel surveys while conducting northern goshawk surveys within and adjacent to properties managed by SDS and other willing adjacent land owners. General surveys were conducted during station placement and surveys for the northern goshawk (see northern goshawk section for location description). Intensive surveys were performed in oak stands in Township 4N, Range 10E, Sections 28, 33, 28; Township 3N, Range 10E, Section 4.

Survey Methods
TECI conducted western gray squirrel surveys in and adjacent to SDS properties (maps 8-10). Surveys were modeled according to the WDFW report “Surveys for western gray squirrel nests on sites harvested under approved forest practice guidelines: analysis of nest use and operator compliance” (Haegen, Van Leuven, and Anderson 2004). TECI biologists performed a general search for western gray squirrels and nests while conducting northern goshawk station placement and surveys. During the general search, TECI’s biologists identified two adult western gray squirrels. Intensive walk-through surveys using serpentine transects were conducted in oak and oak/conifer stands but no squirrels or nests were located.

Survey Results
Turnstone Environmental Consultants, Inc. conducted western gray squirrel surveys in and adjacent to SDS properties (map 7). TECI completed two general site visits and one intensive site visit to protocol during the 2004 western gray squirrel survey season. Two adult western gray squirrels were sighted on June 15th foraging during a goshawk general survey. An intensive search occurred for nest sites in the area where the western gray squirrels were observed. No nests were ever located in the area of the western gray squirrel observations or any other area where intensive surveys were conducted.

Conclusions

Northern Spotted Owl
During the 2003-2004 northern spotted owl breeding season, TECI conducted 9 site visits in the Saddleback Wind Energy Project area. TECI recorded no northern spotted owl observations or responses on any of the 9 site visits during the 2003-2004 field seasons. Based on the surveying parameters of the 1992 Revised Version of “Protocol for Surveying Proposed Management Activities That May Impact Northern Spotted Owls” endorsed by the U.S. Fish and Wildlife and the survey results documented by TECI in the 2 breeding seasons. PPM will not be required to conduct northern spotted owl surveys again until the March 15, 2007. NCASI will continue to monitor the Moss Creek and Mill Creek northern spotted owl historical sites.

Northern Goshawk
No northern goshawk responses or observations were recorded during the 2 site visits during the 2004 breeding season. The 2002 “Survey Methodology for Northern Goshawks in the Pacific Southwest Region” developed by the United States Forest Service (USFS 2002) recommends a two year survey effort. CH2MHILL has negotiated a 1-year survey effort with WDFW. Therefore, no surveys will be conducted in the 2005 northern goshawk breeding season.

Western Gray Squirrel
TECI proposed a 1-year search effort for western gray squirrel nests while conducting northern goshawk surveys. Intensive surveys in oak dominated forests were also conducted in areas of potential impact. No western gray squirrel nests were ever found while conducting these searches. However, while conducting the northern goshawk surveys 2 western gray squirrels were observed. The 2 western gray squirrels were documented in different locations; both were on the ground possibly foraging at the edge of clear-cuts (Map 9). Based on harvest maps provided by CH2MHILL, the first western gray squirrel observation is approximately 3,520 ft from the most easterly wind turbine stringer well outside of the home range of a western gray squirrel (.2 -.47 hectares WDFW "Status of the Western Gray Squirrel (Sciurus griseus) in Washington" July 1993). The second western gray squirrel observation was documented approximately 440ft north of the most easterly stringer. This stringer maybe in the observed western gray squirrel home range based on the .47 hectare home range suggested by WDFW. An intensive survey effort was conducted in and around the western gray squirrel visual with no nests observed.

1. PROJECT OVERVIEW

SDS Lumber Company (SDS) retained the services of Turnstone Environmental Consultants, Inc. (Turnstone) to perform Northern spotted owl (spotted owl), Western gray squirrel (gray squirrel) and Northern goshawk (goshawk) surveys in potential habitat for the Saddleback Wind Energy Project, located in Skamania County, Washington. Survey information will be used to assess the presence, occupancy and reproductive status of spotted owl, gray squirrel and goshawk individuals and populations within areas of proposed management activities.

The physiographic range of spotted owl, gray squirrel and goshawk populations are potentially located within the forestlands of the Saddleback Wind Energy Project. As part of the process to avoid “take” of any state or federally listed species, landowners must conduct surveys to determine the presence of any potentially listed species, prior to conducting any management activities.

Wildlife surveys were conducted using the best information available at the time, following strict adherence to protocol guidelines and habitat requirements to obtain full compliance with agency requirements. All potential habitat and buffers were determined based on the proposed location of the proposed wind turbine locations. In late October of 2008, the final proposed turbine alignment was released and the locations of the turbines were slightly altered from their original location. Following the analysis of the new alignment, Turnstone biologists determined that a few areas that were surveyed for spotted owls, goshawks and gray squirrels in 2008, now did not require surveys, while other areas now required additional survey effort. The survey implications caused by the adjustments to the turbine locations, will be discussed in further detail in the results sections of this document.

2. NORTHERN SPOTTED OWL

Under the federal Endangered Species Act of 1973, the Northern spotted owl (Strix occidentalis caurina) was listed in 1990 as “threatened” by the United States Fish and Wildlife Service. The Washington Fish and Wildlife commission listed the Northern
spotted owl as a state endangered species in 1988 (Buchanan and Swedeen, 2004). Both federal and state agencies determined that the spotted owl is likely to become an endangered species in the foreseeable future throughout all or a significant portion of its existing range. The northern spotted owl’s range extends from Washington State to Northern California. A recently revised species recovery plan is in effect for the northern spotted owl (USFWS 2008).

2.1. Suitable Habitat
In Washington, spotted owls inhabit the Eastern and Western Cascades, Western Lowlands, and Olympic Peninsula Provinces. Within these regions, the spotted owl has specific habitat requirements for nesting, roosting, foraging and dispersal. The species utilizes forests with multi-layered canopies and a high incidence of large trees for nesting and roosting. Fragmented habitats may be used for dispersal and foraging. Spotted owls nest primarily in large tree cavities and on broken tops of large trees. Spotted owls have also been reported as nesting on clumps of mistletoe, on large branches, in abandoned stick nests of Northern goshawks and in cavities of embankments and rock faces (LaHaye 1999).

For the purposes of this project, potentially suitable spotted owl habitat was determined to be coniferous stands with average tree DBH greater than 12 inches and canopy closure of at least 60% or greater. Cut areas or young coniferous plantations that did not meet the minimum DBH or canopy closure parameters were excluded from the survey effort. The resulting designated survey areas would contain nesting roosting, foraging and, dispersal habitat.

2.2. Survey Locations
Turnstone conducted spotted owl surveys within and adjacent to properties managed by SDS and cooperating adjacent landowners. Surveys were conducted in all potentially suitable habitat within the 1.8 mile provincial home range radius of the proposed project area. To determine the potential spotted owl survey areas, the proposed turbine alignments were buffered out to a 1.8 mile radius. This created a large polygon of
potential survey area that included 14,901 acres of land area. This polygon did not contain a contiguous area of potentially suitable spotted owl habitat. Suitable habitat within the overall polygon resembled a patchwork of stands that would require survey.

The delineated potential survey area polygon intersected 2 owl activity centers where historic spotted owl individuals once resided. A designated spotted owl activity center in this area of Washington is equal to a circle with a 1.8 mile radius. The spotted owl activity centers are located on public land north of the project area. The nest cores of these activity centers reside on public land managed by the Washington Department of Natural Resources (WDNR) and the U.S. Forest Service (USFS). Typically spotted owl activity centers will have their status changed to historic after three consecutive years of not being occupied by spotted owls. Currently the state of Washington has a moratorium on changing the status of a known spotted owl activity center to a historic status. The activity center areas intersect (1.8 mile radius provincial range), the northern reach of the delineated potential survey area polygon. The Mill Creek activity center (MSNO# 0991) was located and designated in 1992 and was last considered to have spotted owls present in 2000. The Moss Creek activity center (MSNO#1003) was located and established in 1994 and was last considered to have spotted owls present in 2002. Table 4, in the results section of this document, represents the survey summaries for these activity centers for 1994 thru 2008. These two activity centers are adjacent to one another and overlap by approximately 15%. Due to the adjacency of these spotted owl activity centers, it was decided to survey potential suitable habitat within the activity centers in addition to the survey area determined by 1.8 mile buffer of the proposed turbine alignments. This added an additional 7,222 acres of area that was included in the overall potential survey area. Within this 7,222 acres of area there was a patchwork mix of potentially suitable spotted owl habitat and non-habitat

Table 1. Township and Range information for northern spotted owl survey areas.

| Legal Descriptions for Spotted Owl Survey Areas |
|-----------------|-----------------|-----------------|
| Township        | Range           | Section         |
| 3N              | 9E              | 1,2,11,12,14,23,24,25 |
| 3N              | 10E             | 4-6,7-9,16-18,19,20,30 |
2.3. Survey Methods

Potential northern spotted owl habitat was surveyed in 2008 in accordance with the 1992, revised version of “Protocol for Surveying Proposed Management Activities That May Impact Northern Spotted Owls”. This survey protocol is endorsed by the U.S. Fish and Wildlife Service. Under this protocol, Turnstone initiated the 2-year survey effort in early May of 2008. Under the two year survey methodology, a minimum of 3 visits must be performed for 2 consecutive years in order to determine presence/absence of the spotted owl.

Prior to initiating field surveys, Turnstone biologists analyzed the project area using topographic maps, aerial photography and stand classification data to determine suitable habitat for potential broadcast calling station placement. When possible, broadcast calling stations were placed along ridges and away from streams to maximize coverage by enhancing sound transmission. Broadcast calling stations and survey routes were situated to achieve complete coverage of the potential survey area, preferably with coverage from more than one calling point. Stations were spaced approximately ¼ to ½ mile apart where access was possible and permitted and suitable habitat was present. All broadcast calling stations were surveyed at night when owls are more active and are thought to be more responsive to standard survey techniques (USDI 1992). Per protocol guidelines, Turnstone biologists used ten-minute calling periods at each designated broadcast calling station. Voice hooting, amplified PA systems and “hoot flutes” were used to broadcast both male and female spotted owl vocalizations that included four-note contact calls and various agitated calls. Turnstone conducted surveys between March 15th and August 31st, 2008, as stipulated by the protocol.

During the first round of spot calling, an additional day visit was made to each of the two spotted owl activity centers adjacent to the main project (Mill Crk, and Moss Crk.). The day visits conducted by Turnstone staff were made in addition to the 3 required survey
visits per the protocol guidelines. The intent of these day visits was to further verify if spotted owls were occupying the historic spotted owl nest cores. Turnstone biologists hiked into the historic nest cores and hiked intuitive meandering survey transects, broadcasting spotted owl vocalizations with an amplified PA system while listening for responses.

The Mill Creek and Moss Creek nest cores are currently being surveyed as part of a long term demography study conducted by the Washington Department of Natural Resources on lands within the Klickitat Habitat Conservation Plan Planning Unit. The study was initiated in 2001 and was slated to run for 5 years. In 2007, a new 3 year contract was initiated to extend the survey effort for another 3 years. The fieldwork for the project is carried out by staff from the National Council for Air and Stream Improvement (NCASI), and follows a different standardized survey protocol. Each year NCASI performs a minimum of 6 day/night survey visits to the monitored owl cores. Survey summary details of the survey results for each of these spotted owl cores can be reviewed in Table 4 of this document.

During the 2008 survey season, Turnstone recorded all owl species responses from each calling station during each site visit. Turnstone biologists also recorded all sightings of or responses by potential spotted owl predators to include: barred owls, great horned owls, northern goshawks and other raptor species. The presence of any of these species may affect northern spotted owl responses.

3. Western Gray Squirrel

The western gray squirrel (*Sciurus griseus*) was listed as a “threatened” species by the Washington Fish and Wildlife Commission in 1993. In November of 2007, the State of Washington adopted a species recovery plan for the Western Gray Squirrel which is currently in effect.

In January of 2001, a petition was filed with the United States Fish and Wildlife Service to list the Washington State population of the western gray squirrel as a distinct
population segment (DPS) in an effort to secure protection for the species under the Endangered Species Act of 1973 (ESA). The petition underwent a 12 month period of review and a ruling was announced May 30, 2003. This ruling stated the petition action was not warranted because the Washington population of the Western Gray Squirrel is not a DPS therefore, no protection under the ESA would be granted (Federal Register, 2003). There is currently no federal protection for the western gray squirrel.

The physiographic range and habitat requirements of the western gray squirrel are located within the forestlands of the Saddleback Wind Energy Project.

3.1. Suitable Habitat

Western gray squirrels are arboreal (adapted for living in trees) and, although they forage on the ground, they rarely stray far from trees. They use tree canopies for escape, cover and nesting. Western gray squirrels can move rapidly and cover long distances among tree canopies when canopy conditions permit. A contiguous tree canopy that allows arboreal travel for at least 198 feet (60 meters) around the nest is an important feature of western gray squirrel habitat (Ryan and Carey 1995a). Western gray squirrels are active throughout the day but are most active in the morning. Western gray squirrels are most active in August and September, when they are collecting and storing food for winter, and they are less visible in June and July (Ryan and Carey 1995a).

Currently in Washington, the western gray squirrel distribution has been reduced to three geographically isolated western gray squirrel populations in Washington: the “Puget Trough” population, now centered in Thurston and Pierce counties in the Puget Sound region; the “South Cascades” population in extreme eastern Skamania County and Klickitat and Yakima counties; and the “North Cascades” population in Chelan and Okanogan counties.

In Washington, and elsewhere within the subspecies’ range, the principal food is acorns, although the seeds of Douglas-fir and other conifers are also eaten (Dalquest 1948). While pine nuts and acorns are considered essential foods for storing body fat and conditioning western gray squirrels for winter, green vegetation, seeds and nuts of trees
and shrubs, fleshy fruits, mushrooms and other foods are also consumed. Hypogeous fungi (underground fungi such as truffles) comprise a large portion of the western gray squirrel diet (WDW 1993; Carraway and Verts 1994; Ryan and Carey 1995a).

For the purposes of this project, potentially suitable western gray squirrel potential habitat was defined as any coniferous, deciduous or mixed stands of trees that contained trees with an average diameter at breast height (DBH) of at least 10 inches or greater.

### 3.2. Survey Locations

Turnstone conducted western gray squirrel nest surveys on approximately 738 acres of potentially suitable habitat within the project area. The survey methodology was determined with consultation with a WDFW staff biologist. Within the project area, potential gray squirrel survey areas were determined by using GIS analysis and ground-truthing. The GIS analysis was used to determine areas of potentially suitable squirrel habitat prior to conducting field visits and the ground-truthing was used to validate and finalize the initial GIS analysis.

Western gray squirrel nest surveys were required in any areas where project activities would remove potential western gray squirrel habitat or possibly impact habitat due to structural modification, including stand thinning. Surveys would be required on all habitat that would be altered and continue 400 feet into unaltered habitat. To determine the areas to be surveyed, the proposed energy project infrastructure (primarily proposed wind turbines), was buffered out 150 feet (150 foot radius) to establish a work zone. Then an additional 500 feet of buffer was added, to encompass any areas that may need to be altered due to obstructions (tall trees) within wind corridors of the proposed turbines. Finally an additional 400 feet was buffered onto this distance to satisfy the guideline to survey 400 feet into unaltered habitat. Adding all buffers together, totaled 1,050 foot radius of area to be surveyed. The overall area delineated out by using this buffering process was equal to 1,420 acres. Within this area 738 acres was determined to be potentially suitable western gray squirrel habitat. The remaining 682 acres was determined to be non-habitat for the western gray squirrel.
The survey area was broken up into smaller discrete units to facilitate an efficient survey effort by Turnstone biologists. The discrete units were referred to as polygons and each got a unique identifier. A map of the western gray squirrel survey area polygons is located in Appendix A.

### 3.3. Survey Methods

Surveys were conducted according to the guidelines in the WDFW report, “Surveys for western gray squirrel nests on sites harvested under approved forest practice guidelines: analysis of nest use and operator compliance” (Haegen, Van Leuven, and Anderson 2004). Turnstone biologists performed a general search for western gray squirrels nests and western gray squirrel individuals in the fall of 2008.

Walk-through surveys using meandering transects were conducted in all conifer, deciduous, and mixed composition stands within the designated survey area that met the minimum DBH threshold of 10 inches. Surveyors were looking for squirrel nests and squirrel individuals of any species but focusing their attention on evidence of the western gray squirrel. Transects were oriented to parallel the topographic features of the survey polygons when possible. All transect were laid out systematically to ensure that they were evenly spaced and located close enough together so that no habitat areas were excluded from the survey.

### 4. NORTHERN GOSHAWK

The northern goshawk (*Accipiter gentiles*) is classified as a “species of concern” by the U.S. Fish and Wildlife Service and as a “listed candidate” for sensitive, threatened or endangered species by the Washington Fish and Wildlife Commission. Physiographic range and habitat requirements of the northern goshawk can be found within the forest lands of the Saddleback Wind Energy Project.

#### 4.1. Suitable Habitat

Northern goshawks inhabit a wide variety of forest habitats, including true fir (red fir, white fir, and subalpine fir), mixed conifer, lodgepole pine, ponderosa pine, Jeffrey pine, montane riparian deciduous forest and Douglas fir. Occasionally, goshawks nest in...
coastal redwood and mixed hardwood forests. Goshawk nest sites are associated with patches of forest that are larger and denser than the surrounding landscape. However, home ranges often consist of a wide range of forest age classes and conditions. Numerous habitat studies and modeling efforts have found nest sites to be associated with similar factors, including proximity to water or meadow habitat, forest openings, level terrain or “benches” of gentle slope, northerly aspects and patches of larger, denser trees, but these factors vary widely (Woodbridge 2006).

4.2. Survey Locations

During the 2008 northern goshawk survey window, Turnstone conducted northern goshawk surveys within properties managed by SDS Lumber Co. These surveys covered approximately 1,100 acres of potential goshawk habitat. The potential survey area for the northern goshawk was determined by protocol parameters, consultation with biologists from the Washington Department of Fish and Wildlife and GIS analysis. Survey protocol methodology was outlined in the United States Forest Service document, “Northern Goshawk Inventory and Monitoring Technical Guide, July 2006.” Table 2 depicts the legal descriptions of the where the goshawk survey areas occurred.

It was determined that the ‘Broadcast Acoustical Survey” methodology outlined in this protocol would best suit the needs of the project. This approach requires a one or a two year survey effort determined by the characteristics of the site and the project. Due to the size of the goshawk survey area and the potential level of initial disturbance, a 2 year
survey effort will be used for the original 1,100 acres of potential goshawk habitat. The survey effort for goshawks will be complete after the 2009 surveys are complete.

To determine the area that would require goshawk surveys, a GIS analysis was executed using protocol parameters and available data. The proposed wind energy project infrastructure was buffered out 150 feet to establish a work area that would likely be permanently disturbed. Then an additional 2,624 feet, per protocol recommendations, was added to this initial buffer to establish an area that was considered the potential northern goshawk survey area. Within this area, GIS data was analyzed to identify stands of conifers that may contain suitable habitat structure based on an age class of greater than 25 years and average tree DBH of at least 12 inches. The resulting suitable habitat areas, or polygons, were then overlaid on current aerial photography (2006), to verify that the stands were still intact. This exercise created an initial potential survey area of 3,013 acres of land area. Of this area 1,093 acres was determined to be forested and contain the habitat characteristics needed to support goshawks. Initial calling points and survey transects were then established in GIS to adequately cover the 1,093 acres of potential goshawk habitat that would require survey. During the first goshawk survey field visit additional refinements were made to the goshawk survey areas based on ground-truthing of the potential habitat that was delineated out in GIS.

4.3. Survey Methods

The “broadcast acoustical” survey methodology requires 2 visits to the survey area in a season. The first site visit occurs in the ‘nestling period’, alarm and wail calls are broadcast at the designated calling points. During the second site visit in the ‘fledgling period’, wail and begging calls are broadcast. At each station, goshawk calls were broadcast with a portable amplified PA system for ten seconds. Turnstone biologists pause for thirty seconds to listen for goshawk responses, immediately following the broadcast calls. The sequence of broadcasting and listening for responses was repeated four times at each station, directed toward each of the four cardinal directions. During foot travel between broadcast points, the surveyor is staying alert and listening for
potential goshawk calls and looking for potential goshawk nests. The surveyor is also documenting observations of other raptors species.

Survey periods begin ½ hour before sunrise and conclude ½ hour before sunset, as specified by protocol. If there was a goshawk detected in the project area, then a search for an active nest would ensue, following the ‘intensive search’ protocol. Locating an active nest is recommended immediately following any goshawk detections; however, reviewing results from several surveys and stations can be advantageous for locating active nests. Turnstone also recorded all other incidental raptor species observed during site visit on the field data forms, which are included in Appendix C.

5. Survey Results

5.1. Northern Spotted Owl

Turnstone conducted the first year of spotted owl surveys with a minimum of three visits per calling station on SDS property and some adjacent property (Appendix A). Two spotted owl nest cores located public lands (WDNR, USFS) to the north of the project area were also surveyed. The Mill Creek (MSNO#: 0991) and Moss Creek (MSNO#: 1003) cores are located in Township 4N and Range 10E section 28 and Township 4N and Range 9E section 35, respectively. A total of 80 calling stations were established and surveyed with no northern spotted owl responses or observations. Responses from single barred owls and barred owl pairs were recorded during the three site visits from several different calling stations. The following table summarizes all of the Turnstone survey site results for the project area for the 2008 survey season. A map depicting the locations of the calling stations and locations of other owl observations is available for review in Appendix A of this document.

Table 3 outlines the results of the northern spotted owl surveys at each of the two historic nest cores that intersect the project area. Results in the table were derived from combining data collected by the WDFW, NCASI demography study and Turnstone. The data shows no spotted owls were detected in the Mill Creek core since the 2000 breeding season. The Moss Creek core has not had a spotted owl detected since the 2002 breeding season. Both cores show an increased presence of barred owls detected while conducting the surveys for spotted owls in these areas.

5.2. Alterations to the Northern Spotted Owl Survey Area

The final turbine alignment was released in late October of 2008 did not effect the survey coverage for the areas that were surveyed for spotted owls during the 2008 survey season. Micro-sighting adjustments were made to the north of the project area. Stations
were already set and surveyed due to the two activity centers at the northern reach of the project area.

### 5.3. Western Gray Squirrel

Three field visits were made the western gray squirrel survey areas by a total of three different biologists over a 12 day period. These visits together constituted a complete round of surveys to cover all potential habitat within the survey polygons. During the round of surveys, efforts were made to determine if western gray squirrels were currently using or had historically used any potential habitat within the potential survey area by conducting systematic nest search surveys. The potential survey area was determined using guidelines provided by WDFW staff biologists and GIS analysis. Western gray squirrel surveys were required on any potential western gray squirrel habitat that would be altered by the proposed energy project and include surveys a minimum of 400 feet into adjacent undisturbed potentially suitable squirrel habitat (per WDFW protocol guidelines).

All 26 survey polygons (appendix A) were examined and a formal nest search for western gray squirrel nest structures was performed using guidelines outlined by the protocol, *Surveys for western gray squirrel nests on sites harvested under approved forest practice guidelines*, WDFW 2004. During these visits, no western gray squirrels or western gray squirrel nest structures were observed.

5.4. Alterations to the Western Gray Squirrel Survey Area

The final turbine alignment that was released in late October of 2008 did not affect the survey coverage for the areas that were surveyed for western gray squirrels during the 2008 survey season. The changes made in the final turbine alignment did create additional western gray squirrel survey areas. The survey window to conduct western gray squirrels was still open when the new areas were determined and an additional field visit was conducted and the new areas were surveyed.

5.5. Northern Goshawk

Turnstone conducted protocol northern goshawk surveys on SDS properties during the 2008 goshawk survey window. The survey protocol methodology used was the “broadcast acoustical” methodology, outlined in the protocol; “Northern Goshawk
Calling stations were strategically placed throughout the potential survey area, which was all suitable habitat within 2,624 feet of the designated work areas. Turnstone completed two protocol site visits to 136 calling stations during the 2008 goshawk survey season. One site visit was conducted during the nestling period and the second during the fledgling period as suggested in the protocol. No northern goshawk responses were documented during either of the two site visits. Survey dates and other incidental raptor observations are summarized in Table 6. Maps of the areas surveyed for northern goshawks are available for review in Appendix A. Copies of the field data sheets are available for review in Appendix C.

5.6. Alterations to the Northern Goshawk Survey Area

The final turbine alignment that was released in late October of 2008, did affect the survey coverage for the areas that were surveyed for northern goshawks during the 2008 survey season. The changes made in the final turbine alignment created an additional 367 acres of potential survey area. The survey window to conduct northern goshawks was closed when the new survey areas were determined. These new survey areas will be included in the overall survey effort. The new survey area acreage may be reduced, if ground-truthing efforts in 2009 determine that some areas are composed of non-habitat. Due to the additional survey areas being determined after the close of the 2008 goshawk survey window, and the small size of the areas, a one year survey effort will be initiated in 2009, to the newly designated survey area. The survey methodology used will be the “Intensive Search Survey” protocol as outlined in the United States Forest Service document, “Northern Goshawk Inventory and Monitoring Technical Guide, July 2006.” Under this protocol methodology, the new survey areas will only need to receive a single year of goshawk surveys in order to determine goshawk presence.

Maps of the original and adjusted northern goshawk survey areas can be reviewed in appendix A of this document.

6. CONCLUSION

6.1. Northern Spotted Owl

During the 2008 Northern spotted owl survey season, Turnstone conducted three site visits in each of the designated spotted owl calling points and an additional day visit to two separate nest cores where spotted owls once resided. This survey effort covered potentially suitable northern spotted owl habitat within the approximately 22,123 acre survey area. A total of 80 calling stations were established and surveyed. Turnstone recorded no Northern spotted owl observations or responses during any of these visits. Under the direction of SDS, Turnstone will utilize the calling stations established in 2008 and continue to survey potential habitat within the project area in 2009 in order to ensure proper adherence to the US Fish and Wildlife northern spotted owl survey protocol.
6.2. Western Gray Squirrel

During the 2008 western gray squirrel survey season, Turnstone biologists conducted nest searches to 26 different polygons of potential western gray squirrel habitat. These polygons totaled 738 acres of potentially suitable western gray squirrel habitat. All visits were conducted within the guidelines outlined the appropriate survey protocol. Turnstone biologists did not observe any Western gray squirrels or their nest structures during any of these visits.

Acorn crops from oak trees are an important food source for western gray squirrels. It should be noted that very few oak trees were observed in the project area. The few that were observed within the western gray squirrel survey area boundaries were small (less than 20 feet tall), stunted, and growing in openings on exposed rocky slopes in shallow soils.

6.3. Northern Goshawk

During the 2008 northern goshawk survey season, turnstone conducted surveys at 138 calling points covering 1,100 acres of potentially suitable goshawk habitat. No northern goshawk responses or observations were recorded during the two site visits during the 2008 breeding season. The 2006 “Northern Goshawk Inventory and Monitoring Technical Guide” developed for the United States Forest Service (USFS) recommends a two year survey effort for assessing the occupancy and reproductive status northern goshawks when surveying large tracts of land with the “broadcast acoustical” survey methodology. Under the direction of SDS, Turnstone will conduct surveys in two visits at the same calling stations that were established in 2008 in 2009. Additional survey areas that were added after the close of the 2008 goshawk survey season, will be surveyed in 2009, with a one or two year effort depending on project parameters and consultation with WDFW.

Comments: 43: Short hike due to Rutts/Water Accessible by ATV
45: Bird came in silent and flew off and disappeared for ~5 min then returned + vocalized. Bird that returned may have been a different bird due to inability to sex bird before it disappeared.

Comments:

STA 33/32 Requires Hiking Due to Recon. Road (Road is Accessible by ATV).
36° 40' to 36° 59' may need more clearing due to same hanging small DBH trees.
From field notes:

5/24/2008  Mill Creek NSO core  Observer D. Sahl

1335: started hike into historic Mill creek core down overgrown SDS road. Road becomes undriveable quickly. Would be able to travel with 4 wheeler. Started broadcast calling with PA from the beginning of hike.

1427: dropped of roadbed to meander towards old nest tree/nest tree area. Meandered around stand looking for quality nesting habitat. Found several possible nest trees (large snags), cavities, continued to broadcast with PA and hoot flute, no NSO response.

1623: returned to trailhead (start of old road), no response from any species of owl.
From field notes:

5/25/2008  Moss Creek NSO core   Observer D. Sahl

1230: started hike into historic Moss Creek core down overgrown road off of the mainline road. Was broadcasting with a PA while hiking in a meandering fashion looking for potential NSO nesting habitat/structures Little nesting habitat until you get near the historic nest tree area. Several nice large trees and one great broken topped remnant that may have been an old nest tree. Should be noted that a USFS campground is just downslope and on the other side of the creek from the historic nest tree area. Campground had campers in it at the time of the survey.

1435: PA battery died

1450: returned to trailhead (start of old road), no response from any species of owls.

Comments:
#21 Poor habitat / Power line cut

#7 Poor habitat / Entire ridge has been clearcut / windy

Wind was gusty at times but not usually sustained at our a code rate of 3

Comments:
Almost a full moon on a clear night / Great Screech Conditions
47: Agitated 3/4 - Unknown Spf. Could not use in dark / sound of stationary / may not have fledged yet / will listen tomorrow during daylight and attempt to relocate and ID. (STVA Juvenile Contact only 6/16)
49.5: BAra Sta due to fly over of large bird while driving, no response / likely a juvenile or at some spf.
06/16/2006  Day follow-up at CNK Juvenile @ Station #47

1635 Went back to Sta #47 and hiked around stand broadcasting & observing in area that CNK Juvenile was heard begging the night before.

1910 Located Juvenile STVA. Bird was very skittish and would not vocalize. Bird would fly from tree to tree when I would approach. Followed the Bird around for 220 minutes. Continue to broadcast and attempt to look for a leg band or another STVA or the STRIX.

1630 Left site, Young STVA was a very good flier and can likely hunt on its own. Unable to determine sex of bird due to it not vocalizing at all. No Bands observed. Pair of adult STVA's have been observed/documente 0.95 miles to the NE of where this Juvenile STVA was observed.

Time: Military format (midnight is 0000). Resp. Codes: N = no owl response, A = audio response only, V = visual response only, B (or A, V) = both audio and visual response. Sex: M = male, F = female, U = unknown. Age: A = adult, S = subadult, J = juvenile. Species: STOC = Northern Spotted Owl, STVA = Barred Owl, STRIX = Strix-species unknown, STNE = Great Gray Owl, BUIW = Great Horned Owl, AEAC = Northern Saw-whet Owl, OTKE = Western Screech Owl, GLGN = Northern Pygmy, TYAL = Barn Owl, OTFL = Flammulated Owl. Call Type(s): 4 = 4 Note Call (STOC Only), A = Agitated, B = Bark, CO = Contact Call, JB = Juvenile Begging, W = Whistle/Nest Call, 8 = 8 Note call (STVA only), Stan = (standard) other non-Strix owls.

Comments:
- 44: Only got 2 brief agitated screams then a STVA flew thru and down. Replaced/unknown to relocate.
- 45: Likely the same bird as #44 to brief to get a positive determination on sex of bird.
- 50: Boated observed on RD. Just before RTA & RD.

### Turnstone Environmental Consultants

**Goshawk Survey Form**

**Survey Area/Project Area:** SDS / Hood River  
**Crew:** WCB  
**Month:** June  
**Day:** 25  
**Year:** 2008  
**Visit #:** 1

**Wind Codes:**
- 1 = Light air (>1 mph) 
- 2 = Light breeze (1-3 mph) 
- 3 = Gentle breeze (4-7 mph) 
- 4 = Light wind (8-12 mph) 
- 5 = Wind (>12 mph)

**Weather Codes:**
- CI = Clear, FG = Fog 
- PC = Partly Cloudy, OC = Overcast, DR = Drizzle, 
- RN = Rain, SN = Snow

County: Skamania

Date(s) Surveyed: 10/14/2008

County: Skamania

Start/Stop time(s): 0847-Start/1635-Stop

Surveyor Names and Affiliations: Devin Sahl (TECI)

Contact Name, Address, & Phone:

TECI
Turnstone Environmental Consultants Inc.
18000 NW lucy Reeder Rd Portland, OR  97231
503-621-9613

Directions to Site:

Be specific enough to allow someone unfamiliar with the site to find it.

From the Jct. of Cook Underwood Rd. and Knapp Rd. Go NW on Knapp Rd. for ~0.1miles to Scoggins Rd., Turn right onto Scoggins Rd. and ~100 yards to Jct. with private drive on left (Signed as CG 2930). Proceed up CG 2930 to access SDS and WDNR lands.

Description of Habitat at Site:

Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.

All polygons surveyed were composed of mixed conifer/hardwoods, primarily PSME with some scattered THFL/TSHE. The majority of the overstory PSME appears to be >25 years of age, with some scattered remnant PSME >70 years. A few small patches of Quercus spp (likely Quercus Garryana), were observed within the boundaries of the A3 polygon. The trees were not > than 15ft. in height and growing in a few steep, rocky, open areas with a westerly aspect. In Polygons A3 and A7 there were numerous ACMA present, especially towards the toe of the slope. Slopes within the polygon boundaries vary between ~0% to 85%. The aspect of each polygon also varies. The A1 polygon has a southern aspect, A3 has a predominantly western aspect and several insised drainages. The A7 polygon has a variety of aspects, primarily eastern and northern. Water was present in seasonally intermittent streams in polygon A3 on the north end and in A7 in a broader drainage that runs through the center of the polygon. Both contained some water at time of survey, streambanks indicate that the water level increases significantly during the wet season. No areas of standing water were observed in any of the polygons.

No Western Gray squirrels, or their nest structures were observed during the survey. Several bird nests were observed and numerous douglas squirrels were heard and a few were observed.
Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. For each map, attach one Map Label and one or more Western Gray Squirrel Survey Data Sheets. If you see or hear a western gray squirrel please fill out a wildlife observation form and attach.

Mark Water Sources and Survey Transect or Survey Polygon on Attached Map.

Name of Area Surveyed: Polygons:A4, A5, A10 (See Map)
(Use a generic geographic name like "Yahne Canyon". Add the timber sale name/number if available.)

Location (TRS): T 3N R 10E S 5,6,7,8 County: Skamania

Date(s) Surveyed: 10/14/2008
Start/Stop time(s): 0845-Start/1635-Stop

Surveyor Names and Affiliations: John Kolozar (TECI)

Contact Name, Address, & Phone:

Directions to Site: Be specific enough to allow someone unfamiliar with the site to find it.
From the Jct. of Cook Underwood Rd. and Knapp Rd. Go NW on Knapp Rd. for ~0.1miles to Scoggins Rd., Turn right onto Scoggins Rd. and ~100 yards to Jct. with private drive on left (Signed as CG 2930). Proceed up CG 2930 to access SDS and WDNR lands.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.
All polygons surveyed were composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSHE. The majority of the overstory PSME appears to be >25 years of age, with some scattered remnant PSME >70 years. No patches of Quercus SPP. were observed within the boundaries of the A4,A5 or A10 polygons. In all the Polygons there were ACMA and ACCI present within the polygons. Slopes within the polygon boundaries vary between ~0% to 45%. The aspect of each polygon also varies. The A4 polygon has a southwest aspect, A5 has a predominantly eastern aspect. The A10 polygon was fairly flat and had a subtle northern aspect. No standing water or active drainages were observed in the polygons.

No Western Gray squirrels, or thier nest structures were observed during the survey. Several bird nests were observed and numerous douglas squirrels were heard and a few were observed.
Western Gray Squirrel Survey - Cover Sheet

Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. For each map, attach one Map Label and one or more Western Gray Squirrel Survey Data Sheets. If you see or hear a western gray squirrel please fill out a wildlife observation form and attach.

Mark Water Sources and Survey Transect or Survey Polygon on Attached Map.

From the Jct. of Cook Underwood Rd. and Knapp Rd. Go NW on Knapp Rd. for ~0.1 miles to Scoggins Rd., Turn right onto Scoggins Rd. and ~100 yards to Jct. with private drive on left (Signed as CG 2930). Proceed up CG 2930 to access SDS and WDNR lands.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.

All polygons surveyed were composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSHE. The majority of the overstory PSME appears to be >25 years of age, with some scattered remnant PSME >70 years. No patches of Quercus spp. were observed within the boundaries of the A2, A6 or A9 polygons. In all the Polygons there were ACMA present. Slopes within the polygon boundaries vary between ~0% to 45%. The aspect of each polygon also varies. The A2 polygon has a southern aspect, A6 has a predominantly southwestern aspect and an active drainage. The A9 polygon was fairly flat and had a slight northeastern aspect. Water was present in seasonally intermittent stream and a small roundish pond (~30 feet across at time of survey) in polygon A6. Water in the pond appeared to be present year round. Both contained some water at time of survey, streambanks indicate that the water level increases significantly during the wet season.

No Western Gray squirrels, or their nest structures were observed during the survey. Several bird nests were observed and numerous Douglas squirrels were heard and a few were observed.
Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. For each map, attach one Map Label and one or more Western Gray Squirrel Survey Data Sheets. If you see or hear a western gray squirrel please fill out a wildlife observation form and attach.

Mark Water Sources and Survey Transect or Survey Polygon on Attached Map.

**Description of Habitat at Site:** Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.

The A12 and A13 polygons were composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSHE. The majority of the overstory in the stands in these polygons was PSME and appears to be mixed age, most was >20 years of age with a few older remnant trees present. No patches of Quercus SPP, were observed within the boundaries of the polygons. There was some ACMA and ACCI present within the polygons. Both polygons are very flat with slopes within the polygon boundaries vary between ~0% to 5%. Both polygons had very marginal potential WGS habitat. There were no drainages or areas of standing water present within the polygons.

No Western Gray squirrels, or thier nest structures were observed during the survey. Several bird nests were observed and numerous douglas squirrels were heard and a few were observed.
Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. **Description of Habitat at Site:** Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.

The A14 polygon was composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSHE. The majority of the overstory PSME appears to be >25 years of age, stand appeared to be even aged. No patches of Quercus SPP. were observed within the boundaries of the polygon. There was some ACMA and ACCI present within the polygon. Slopes within the polygon boundaries vary between ~0% to 60%. The A14 polygon has a westerly aspect and one seasonal drainage. The drainage was dry at the time of the survey. No standing water or active drainages were observed at the time of survey.

No Western Gray squirrels, or thier nest structures were observed during the survey. Several bird nests were observed and numerous douglas squirrels were heard and a few were observed.
Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. These polygons were lumped together because they were visited by three surveyors simultaneously on the same day. The A11, A17 and A18 polygons were composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSHE. The majority of the overstory in the stands in these polygons was PSME and appears to be mixed age, most was >20 years of age. No patches of Quercus SPP. were observed within the boundaries of the polygons. There was some ACMA and ACCI present within the polygons. Slopes within the polygon boundaries vary between ~0% to 60%. The A11 polygon has multiple pieces all of which contained very marginal potential WGS habitat. There are two seasonal drainages within the area of the polygons and both were dry at the time of the survey. The A17 and A18 polygons were on the extreme southern end of the project area. A18 has a northwestern aspect on a fairly steep slope and a seasonal drainage that was dry at the time of the survey. The A17 polygon had a south and southeast exposure and no significant drainages. It had trees older than the other 2 polygons in the overstory and a few remnant PSME present that were greater than 70yrs of age. The A17 polygon is adjacent to the C1 polygon that had a seasonal stream present in it that had several pools of water present but no

No Western Gray squirrels, or thier nest structures were observed during the survey. Several bird nests were observed and numerous douglas squirrels were heard and a few were observed.

**Directions to Site:** Be specific enough to allow someone unfamiliar with the site to find it.

From the Jct. of Cook Underwood Rd. and Knapp Rd. Go NW on Knapp Rd. for ~0.1miles to Scoggins Rd., Turn right onto Scoggins Rd. and ~100 yards to Jct. with private drive on left (Signed as CG 2930). Proceed up CG 2930 to access SDS and WDNR lands.

This set of "B" polygons was surveyed after the "A" polygons due to alterations in the ailingment of the proposed turbine strings.

**Description of Habitat at Site:** Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.

All polygons surveyed were composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSHE. The majority of the overstory PSME appears to be >25 years of age, with some scattered remnant PSME >70 years. No Quercus spp. were observed within the boundaries of the polygons surveyed. In Polygons B3, B4 and B5 there were numerous ACMA present. Slopes within the polygon boundaries vary between ~0% to 70%. The aspect of each polygon also varies. Water is present in seasonally intermittent streams in polygons B4 and B5. The intermittent stream in B5 was active at time of survey, the intermittent stream in B4 was not.

No Western Gray squirrels, or thier nest structures were observed during the survey. One potential nest structure was examined from the ground and determined to have potential to be a douglas squirrel nest. The structure was quite small and constructed ~25 feet up in a small ACMA. The structure appeared to be a small ball (less than 14” in diameter) constructed primarily of lichen, twigs and a few ACMA leaves. Several douglas squirrel cone middens were located in the immediate vicinity. While exploring the immediate area of the nest looking for other possible nest structures, the surveyor observed 3 distinct douglas squirrel individuals.
Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. For each map, attach one Map Label and one or more Western Gray Squirrel Survey Data Sheets. If you see or hear a western gray squirrel please fill out a wildlife observation form and attach.

From the Jct. of Cook Underwood Rd. and Knapp Rd. Go NW on Knapp Rd. for ~0.1miles to Scoggins Rd., Turn right onto Scoggins Rd. and ~100 yards to Jct. with private drive on left (Signed as CG 2930). Proceed up CG 2930 for ~2.8 miles to powerline ROW. Turn Left onto the powerline ROW road and proceed ~100 yards to unmarked spur on Left. Continue down Spur road ~0.25 to just before it’s end and park. You are parked just outside the NE corner of the polygon.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.
Polygon is a stand of mixed conifer/hardwood, primarily PSME with some scattered THPLSHE. The polygon encompasses both sides of a small intermittent stream. The majority of the overstory PSME appears to be >50 years of age, with some scattered remnant PSME >70 years. No Quercus SPP. Were observed within the boundaries of the polygon but may be present just outside the boundary at the transition to agricultural land (fruit orchard). Slopes within the polygon boundary vary between ~0% to 60% depending on location. The aspect is predominantly SE facing on the western portion of the tract and SSW facing on the eastern portion of the tract, with the intermittent stream being the divider between. Water is present in a seasonally intermittent stream that runs through the middle of the polygon. The stream was predominantly dry at the time of the survey expect for a few small puddles and some water in a maintained penstock that supplies water to landowners downslope. A small, shallow pond was present backed-up behind a non-maintained irrigation structure just outside the SE corner of the polygon. The irrigation structure is designed to impound water form the seasonaly intermittent stream. It is possible that the irrigation structure would hold some amount of water year round that would be available for wildlife.

No Western Gray squirrels were observed during the survey of this polygon. One potential nest structure was examined from the ground and determined to have potential to be a western gray squirrel nest structure. A subsequent visit to the site 7 days after this visit determined that the structure was a broom type growth emanating form the bole of the PSME. The structure was examined by climbing an adjacent tree and determined to not be a squirrel nest. Several douglas squirrels were heard and observed within the boundaries of the polygon during the time of the survey and on subsequent visits.
2009 Final Report

Results of Northern Spotted Owl, Western Gray Squirrel and Northern Goshawk Surveys Conducted for the Whistling Ridge Wind Energy Project

1. PROJECT OVERVIEW

SDS Lumber Company (SDS) retained the services of Turnstone Environmental Consultants, Inc. (Turnstone) to perform Northern spotted owl (spotted owl), Western gray squirrel (gray squirrel) and Northern goshawk (goshawk) surveys in potential habitat for the Whistling Ridge Wind Energy Project formally known as the Saddleback Wind Energy Project, located in Skamania County, Washington. Survey information will be used to assess the presence, occupancy and reproductive status of spotted owl, gray squirrel and goshawk individuals and populations within areas of proposed wind energy development.

The physiographic range of spotted owl, gray squirrel and goshawk populations are potentially located within the forestlands of the Whistling Ridge Wind Energy Project. As part of the process to avoid “take” of any state or federally listed species, landowners must conduct surveys to determine the presence of listed species, prior to conducting any management activities.

This report summarizes the Wildlife surveys that were conducted in both 2008 and 2009 at the Whistling Ridge Wind Energy Project. All Wildlife surveys were conducted using the best information available during this time period. Turnstone staff followed strict adherence to protocol guidelines and habitat requirements to obtain full compliance with agency requirements and recommendations. All potential habitat and buffers were determined based on the sighting of the proposed wind turbine locations. In late October of 2008, the final proposed turbine alignment was released and the locations of the turbines were slightly altered from their original location. Turnstone re-analyzed the new alignment, confirming all additional buffers were covered and that the adherence to protocols for all species surveyed were sufficient. The survey implications of the adjustments to the proposed turbine locations will be discussed in further detail in the survey locations sections for each of the respective species surveyed.
2. NORTHERN SPOTTED OWL

Under the federal Endangered Species Act of 1973, the Northern spotted owl (*Strix occidentalis caurina*) was listed in 1990 as "threatened" by the United States Fish and Wildlife Service. The Washington Fish and Wildlife commission listed the Northern spotted owl as a state endangered species in 1988 (Buchanan and Swedeen, 2004). Both federal and state agencies determined that the spotted owl is likely to become an endangered species in the foreseeable future throughout all or a significant portion of its existing range. The northern spotted owl’s range extends from Washington State to Northern California. A recently revised USFWS species recovery plan is in effect for the northern spotted owl (USFWS 2008).

2.1. Suitable Habitat

In Washington, spotted owls inhabit the Eastern and Western Cascades, Western Lowlands, and Olympic Peninsula Provinces. Within these regions, the spotted owl has specific habitat requirements for nesting, roosting, foraging and dispersal. The species utilizes forests with multi-layered canopies and a high incidence of large trees for nesting and roosting. Fragmented habitats may be used for dispersal and foraging. Spotted owls nest primarily in large tree cavities and on broken tops of large trees. Spotted owls have also been reported as nesting on clumps of mistletoe, on large branches, in abandoned stick nests of Northern goshawks, and in cavities on embankments and rock faces (LaHaye 1999).

For the purposes of this project, potentially suitable spotted owl habitat was determined to be coniferous stands with average tree DBH (diameter at breast height) greater than 12 inches and canopy closure of 60% or greater. These standards for suitable spotted owl habitat were based on the availability of forest stand classification GIS data from SDS. By using GIS data that was readily available, initial spotted owl survey areas could be efficiently determined in the office and verified in the field when setting up the survey stations.

The 12” average DBH and 60% canopy closure standards could be considered conservative as compared to the nesting and roosting habitat characteristics that are
discussed in the 2008 USFWS recovery plan. This plan states, “Features that support nesting and roosting typically include a moderate to high canopy closure (60 to 90 percent); a multilayered, multi-species canopy with large overstory trees (with diameter at breast height [dbh] of greater than 30 inches); a high incidence of large trees with various deformities (large cavities, broken tops, mistletoe infections, and other evidence of decadence); large snags; large accumulations of fallen trees and other woody debris on the ground; and sufficient open space below the canopy for spotted owls to fly (Thomas et al. 1990).” These types of habitats are typically not present over large areas on managed commercial forest lands. Recently cut areas or young conifer plantations that did not meet the minimum average DBH or canopy closure parameters were excluded from the survey effort. The resulting designated survey areas did contain varying types of habitat that could potentially be used by spotted owls.

2.2. Survey Locations

Turnstone conducted spotted owl surveys within and adjacent to properties managed by SDS and cooperating adjacent landowners. Surveys were conducted in all potentially suitable habitat within the 1.8 mile spotted owl provincial home range radius of the proposed project area. To determine the potential spotted owl survey areas, the proposed turbine alignments were buffered out to a 1.8 mile radius. This created a large polygon of potential survey area that included 14,901 acres. This initial query of potential habitat that fell within the provincial range was not contiguous, it resembled a patchwork of stands that met the survey threshold and would require spotted owl surveys.

The delineated potential survey area polygon intersected two owl activity centers where spotted owls historically lived. A designated spotted owl activity center in this geographical region of Washington is equal to a circle with a 1.8 mile radius. The two spotted owl activity centers are located primarily on public lands north of the project area. The nest cores of these activity centers reside on public land managed by the Washington Department of Natural Resources (WDNR) and the U.S. Forest Service (USFS).
The activity centers intersect (1.8 mile radius provincial range) the northern reach of the proposed wind turbine survey area polygon. The Mill Creek activity center (MSNO#0991) was located and designated in 1992 and was last considered to have spotted owls present in 2000. The Moss Creek activity center (MSNO#1003) was located and established in 1994 and was last considered to have spotted owls present in 2002. Table 4, in the results section of this document, represents the survey summaries for these activity centers for 1994 thru 2009. These two activity centers are adjacent to one another and overlap by approximately 15%. Because of the close proximity of the spotted owl activity centers all suitable habitat within a 1.8 mile buffer of the nest site was surveyed. This increased the potential survey area to 7,222 acres. Much of this habitat was a patchwork of timber stands that contained potentially suitable and non-suitable habitat.

The final proposed turbine alignment released in late October of 2008 did not affect the survey coverage area for spotted owls during the 2008 survey season. The additional turbines were located to the north end of the project area where surveys were already being conducted in the Mill and Moss Creek activity centers.

### 2.3. Survey Methods

Potential northern spotted owl habitat was surveyed in 2008 and 2009 in accordance with the 1992, revised version of “Protocol for Surveying Proposed Management Activities That May Impact Northern Spotted Owls”. This survey protocol is endorsed by the U.S. Fish and Wildlife Service. Under this protocol, Turnstone initiated the 2-year
survey effort in early May of 2008 and completed the second year of spotted owl surveys in August of 2009. Under the two year survey methodology, a minimum of 3 protocol visits must be performed for 2 consecutive years in order to determine probable presence/absence of the spotted owl.

Prior to initiating field surveys, Turnstone biologists analyzed the project area using topographic maps, aerial photography and stand classification data to determine suitable habitat for potential broadcast calling station placement. Calling stations were placed in differing topographies across the survey area of potential habitat. When possible, broadcast calling stations were placed along ridges and prominent points to maximize coverage and increase the probability of hearing distant owl responses. Broadcast calling stations and survey routes were situated to achieve complete coverage of the potential survey area, preferably with coverage from more than one calling point. Stations were spaced approximately ¼ to ½ mile apart where access was possible and permitted. Broadcast calling stations were surveyed at night when owls are more active and are thought to be more responsive to standard survey techniques (USDI 1992). Per protocol guidelines, Turnstone biologists used a minimum of ten-minute calling periods at each designated broadcast calling station. Amplified PA systems were the primary means used to broadcast both male and female spotted owl vocalizations that included four-note contact calls and various agitated calls. Voice hooting and “hoot flutes” were occasionally used to supplement the Amplified PA systems and were also used when conducting daytime visits to historic nest cores. Turnstone conducted surveys between March 15th and August 31st during each survey year, as stipulated by the protocol.

During the first round of broadcast calling in the 2008 survey season, an additional day visit was made to each of the two spotted owl nest core activity centers north of the project area, (Mill Crk, and Moss Crk.). During the 2009 survey season, three additional day visits were made to each of the two spotted owl nest core activity centers. After consulting with WDFW staff, additional day visits were added in 2009. The intent of these day visits was to further verify if spotted owls were “quietly” occupying the historic spotted owl nest cores but not responding during night surveys. The three day visits conducted by Turnstone staff were made in addition to the three required night surveys outlined in the survey protocol guidelines. These visits involved hiking into the
historic nest core areas and conducting an intensive survey of the area using meandering survey transects in areas of suitable habitat. Turnstone staff attempted to elicit responses from spotted owls using various means while conducting these surveys. Surveys near the nest cores would typically start out with subtle voice or hoot flute calling and then proceed into more aggressive and louder calling using amplified PA systems when no responses or observations occurred. The visits varied in length but typically lasted from two to six hours.

Both the Mill and Moss Creek nest cores are also being surveyed as part of a long term demography study conducted by the Washington Department of Natural Resources on lands within the Klickitat Habitat Conservation Plan Planning Unit. The study was initiated in 2001 and was slated to run for five years. In 2007, a new three year contract was signed to extend the survey effort for another three years. The fieldwork for the project is carried out by staff from the National Council for Air and Stream Improvement (NCASI). Each year NCASI performs a minimum of three visits and as many as 10 survey visits a year to the spotted owl nest cores. These visits involve both day calling the historic nest cores and night calling in the same areas. Survey summary details of the survey results for each of these spotted owl cores can be reviewed in Table 4 of this document.

During the 2008 and 2009 survey seasons, Turnstone biologists recorded all owl species encountered and the sightings of or responses by, potential spotted owl predators. This included barred owls, great horned owls, northern goshawks and other raptor species. There is some evidence that the presence of these species may affect northern spotted owl responses.

3. Western Gray Squirrel

The western gray squirrel (Sciurus griseus) was listed as a “threatened” species by the Washington Fish and Wildlife Commission in 1993. In November of 2007, the State of Washington adopted a species recovery plan for the Western Gray Squirrel which is currently in effect.
In January of 2001, a petition was filed with the United States Fish and Wildlife Service to list the Washington State population of the western gray squirrel as a distinct population segment (DPS) in an effort to secure protection for the species under the Endangered Species Act of 1973 (ESA). The petition underwent a 12 month review with a ruling announced on May 30, 2003. This ruling stated the petition action was not warranted because the Washington population of the Western Gray Squirrel is not a DPS therefore, no protection under the ESA would be granted (Federal Register, 2003). There is currently no federal protection for the western gray squirrel.

The physiographic range and habitat requirements of the western gray squirrel are located within the forestlands of the Whistling Ridge Wind Energy Project.

### 3.1. Suitable Habitat

Western gray squirrels are arboreal (adapted for living in trees) and, although they forage on the ground, they rarely stray far from trees. They use tree canopies for escape, cover and nesting. Western gray squirrels can move rapidly and cover long distances among tree canopies when canopy conditions permit. A contiguous tree canopy that allows arboreal travel for at least 198 feet (60 meters) around the nest is an important feature of western gray squirrel habitat (Ryan and Carey 1995a). Western gray squirrels are active throughout the day but are most active in the morning. Western gray squirrels are most active in August and September, they are less visible in June and July (Ryan and Carey 1995a) while collecting and storing food for winter.

In Washington the western gray squirrel distribution has been reduced to three geographically isolated western gray squirrel populations: the “Puget Trough” population now centered in Thurston and Pierce counties in the Puget Sound region; the “South Cascades” population in extreme eastern Skamania County and Klickitat and Yakima counties; and the “North Cascades” population in Chelan and Okanogan counties.

In Washington, and elsewhere within the gray squirrels range, the principal food is acorns, although the seeds of Douglas-fir and other conifers are also eaten (Dalquest 1948). While pine nuts and acorns are considered essential foods for storing body fat
Hypogeous fungi (underground fungi such as truffles) comprise a large portion of the western gray squirrel diet (WDW 1993; Carraway and Verts 1994; Ryan and Carey 1995a).

For the purposes of this project, potentially suitable western gray squirrel habitat was defined as any coniferous, deciduous or mixed stands of trees that have an average diameter at breast height (DBH) of at least 10 inches or greater. This criterion was used to ensure a conservative approach in determining survey areas.

3.2. Survey Locations

Turnstone conducted 2 rounds of western gray squirrel nest surveys within the project area. Approximately 738 acres of potentially suitable habitat within the project area were surveyed in the fall of 2008. The survey area was adjusted slightly in 2009 removing 46 acres from the overall survey effort. This area turned out to be outside the established buffers. In the Spring of 2009, a total 692 acres were surveyed for western gray squirrels.

Within the project area, potential gray squirrel survey areas were selected by identifying appropriate stand inventories using GIS analysis and ground-truthing. The initial GIS analysis was used to efficiently determine areas of potentially suitable squirrel habitat prior to conducting the field visits. Ground-truthing was used to validate and finalize the initial GIS analysis while setting up the squirrel survey area blocks.

Western gray squirrel nest surveys were completed in any areas where project activities would remove or structurally modify forest stands. To determine survey areas the proposed wind turbine string was buffered out 150 feet (150 foot radius) to establish a work zone. Then an additional 500 feet of buffer was added, to encompass any areas that may be altered due to obstructions (tall trees) within wind corridors of the proposed turbines. Finally, an additional 400 feet was added as an unaltered habitat buffer. Adding all buffers created a 1,050 foot radius around the turbine string to be surveyed.
Including all buffers the entire survey area of possible habitat was nearly 1,361 acres. Within this area 738 acres were determined to be potentially suitable western gray squirrel habitat in 2008 and 692 acres in 2009. The remaining area within the overall buffer was not surveyed and determined to be non-habitat.

The survey area was broken up into smaller discrete units to facilitate an efficient and systematic survey effort by Turnstone biologists. The discrete units were referred to as polygons and each polygon was given a unique identifier. A map of the western gray squirrel survey area polygons is located in Appendix A.

The final proposed turbine alignment released in late October of 2008 did change the survey coverage for western gray squirrels. The changes made in the final turbine alignment did add additional habitat. These stands were a patchwork of small isolated forests that needed an additional survey. The survey window to conduct western gray squirrel surveys was still open when the new areas were identified. An additional field visit was conducted in early November using the same survey methodology as the first round of squirrel surveys in 2008.

3.3. Survey Methods

Surveys were conducted according to the guidelines in the WDFW report, “Surveys for western gray squirrel nests on sites harvested under approved forest practice guidelines: analysis of nest use and operator compliance” (Haegen, Van Leuven, and Anderson 2004). Turnstone biologist also worked with WDFW staff biologists to configure the best survey methodology for the area.

Turnstone biologists performed a general search for western gray squirrels and their nests in the fall of 2008 and the spring of 2009. Walk-through surveys using meandering transects were conducted in all conifer, deciduous, and mixed composition stands within the designated survey area that met the minimum DBH threshold of 10 inches. Surveyors identified all species of squirrels, evidence of squirrel activity and squirrel nests while walking transects. Transects were oriented to parallel the topographic features of the survey polygons when possible to facilitate safe and efficient travel on foot. All transects were laid out systematically in GIS to ensure that they were evenly
spaced and located close enough together so that no habitat areas were excluded from
the survey effort. Surveyors would use the plotted transects as general guidelines for a
route of travel. The survey was conducted using an intuitive meander of the survey area.
Surveyors would deviate from the designated transect to investigate areas of potential
habitat or the evidence of squirrel sign.

4. NORTHERN GOSHAWK

The northern goshawk (*Accipiter gentiles*) is classified as a “species of concern” by the
U.S. Fish and Wildlife Service and as a “listed candidate” for a state sensitive,
threatened, or endangered species by the Washington Fish and Wildlife Commission.
The physiographic range and habitat requirements of the northern goshawk can be
found within the forest lands of the Whistling Ridge Wind Energy Project.

4.1. Suitable Habitat

Northern goshawks inhabit a wide variety of forest habitats, including true fir (red fir,
white fir, and subalpine fir), mixed conifer, lodgepole pine, ponderosa pine, Jeffrey pine,
montane riparian deciduous forest and Douglas fir. Occasionally, goshawks nest in
cosatal redwood and mixed hardwood forests. Goshawk nest sites are associated with
patches of forest that are larger and denser than the surrounding landscape. However,
home ranges often consist of a wide range of forest age classes and conditions.
Numerous habitat studies and modeling efforts have found nest sites to be associated
with similar factors, including proximity to water or meadow habitat, forest openings,
level terrain or “benches” of gentle slope, northerly aspects and patches of larger,
denser trees, but these factors vary widely (Woodbridge 2006).

4.2. Survey Locations

During the 2008 and 2009 northern goshawk survey windows, Turnstone staff conducted
northern goshawk surveys within properties managed by SDS Lumber Co. and on lands
managed by WDNR. These surveys covered approximately 1,493 acres of potential
goshawk habitat. The objective of our survey effort was to determine the presence of
northern goshawks.
The potential survey area for the northern goshawk was determined by protocol parameters, consultation with biologists from the WDFW, and GIS analysis. Survey protocol methodology was outlined in the United States Forest Service document, “Northern Goshawk Inventory and Monitoring Technical Guide, July 2006.” Table 2 depicts the legal descriptions of the where the goshawk survey areas occurred.

Table 2. Township and Range information for northern goshawk survey areas.

To determine the area that would require goshawk surveys, a GIS analysis was conducted following the protocol parameters and best available data. The proposed wind turbine right of way was buffered out 150 feet to establish a work area that would likely be permanently disturbed. Then an additional 2,624 feet (800 meters), per protocol recommendations, was added to 50ft buffer to establish an area that was considered the potential northern goshawk survey area. Within this area, GIS data was analyzed to identify conifer stands that may contain suitable habitat structure based on an age class of greater than 25 years and average tree DBH of at least 12 inches.

The resulting suitable habitat areas, or polygons, were then overlaid on current aerial photography (2006), to eliminate any recently harvested stands. This exercise created an initial survey area of 3,013 acres of potential habitat. Of this area approximately 1,100 acres were determined to be forested and contain the habitat characteristics needed to support goshawks. Initial calling points and survey transects were then established in GIS to adequately cover the 1,100 acres of potential goshawk habitat that would require survey.
In order to adequately survey the approximately 1,100 acres of potential goshawk habitat, Turnstone biologists conducted field reconnaissance in areas of all potential habitat that was delineated out in GIS. After ground-truthing the area 136 calling points were set. The areas to be surveyed had irregular shapes and establishing standardized transect strings was not feasible. Survey areas were covered with individual calling points that were placed within the potential goshawk habitat. The objective was to place stations within 150 meters of all potential habitat and to not place stations more than 200 meters apart.

The final proposed turbine alignment was released in late October of 2008. This realignment affected the survey coverage to the north of the project site. The changes made in the alignment created an additional 367 acres in the buffered area of potential habitat. The survey window to conduct northern goshawk surveys during the 2008 breeding season had closed making it impossible to survey the additional habitat intersected by the re-alignment. Because the new area was small, Turnstone biologists chose a different survey methodology in the 2009 northern goshawk survey window. The “Intensive Search Survey” methodology was chosen and initiated in summer of 2009. The details of this survey methodology are outlined in the USFS document, “Northern Goshawk Inventory and Monitoring Technical Guide, July 2006.” This methodology was selected because it could be initiated and completed in a single survey season. Under this rigorous approach, the new survey areas would receive two successive survey visits using a more intense survey methodology in order to determine potential goshawk presence.

During the 2009 survey effort, approximately 34 acres of non-habitat was eliminated from the original 367 acres. An additional 56 acres was added adjacent to the area because of its potential habitat qualities making the total approximately 389 acres of potential habitat. These areas were surveyed using the intensive search methodology while approximately 1,100 acres were surveyed for the second year using the broadcast acoustic methodology.
4.3. Survey Methods

Two different survey methodologies were used during the 2008 and 2009 goshawk survey windows. In 2008 and 2009, two rounds of the “Broadcast Acoustic” surveys were conducted. In 2009 two rounds of the “Intensive Search” survey methodology was conducted where the turbine alignment was extended to the north.

The “broadcast acoustical” survey methodology requires 2 visits to the survey area within a breeding season. The first site visit occurs in the ‘nestling period’, where adult alarm calls are broadcast at the designated calling points. During the second site visit, in the ‘fledgling period’, wail and fledgling begging calls are broadcast at the same survey points.

At each station, goshawk calls are broadcast with a portable amplified PA system for ten second periods. Turnstone biologists pause for thirty seconds to listen for goshawk responses, immediately following the broadcast calls. The sequence of broadcasting and listening for responses was repeated two more times, rotating 120 degrees from the last broadcast. The three-call sequence was repeated again, so that each direction received two sets of broadcast calls. During foot travel between broadcast points, the surveyors stayed alert observing and listening for potential goshawks. Surveyors also documented observations of other raptor species when encountered.

Survey periods begin ½ hour before sunrise and conclude ½ hour before sunset, as specified by protocol. If there was a goshawk detected in the project area, then a search for an active nest would ensue, following the ‘intensive search’ protocol. Locating an active nest is recommended immediately following any goshawk detections. Turnstone also recorded all other incidental raptor species observed during site visits on the field data forms, which are included in Appendix C.

The second methodology used in 2009 was the “Intensive Search Survey” methodology. This approach requires one or more visits to the survey area in a breeding season to determine goshawk occupancy. Turnstone biologists chose two site visits in 2009 to reach a high level of assurance that they were not missing goshawks. This survey method combines an intensive visual search with the methods of the “broadcast
acoustic” protocol. The visual search involves multiple surveyors looking for any possible goshawk sign, which could include: nests (active or abandoned), whitewash, prey remains, plucking posts, or molted feathers. Goshawk calls are broadcast while conducting the visual search as recommended in the guidelines in the “broadcast acoustic” protocol.

To be most effective the survey requires the use of multiple observers simultaneously walking the stands. All intensive search surveys conducted used a minimum of three simultaneous observers and sometimes four when necessary to adequately cover the area. Survey transects were established to cover the entire 389 acre site. These transects were overlaid on topographic base maps and aerial photographs in GIS. Start points and end points of the survey transects were then derived and loaded into GPS units to be used as reference tools in the field while conducting the surveys. GPS units also served as a reliable method to mark and map any goshawk observations.

Turnstone biologists began their survey effort later in the nesting period in an attempt to cause fewer disturbances to potential nesting goshawks. Surveys were conducted walking parallel transects in unison with multiple observers looking for goshawk sign and broadcasting goshawk calls. Survey transects were established approximately 20-30 meters apart depending on the terrain and the amount of understory vegetation present. The observer walking the middle transect would broadcast goshawk calls approximately every 250 meters apart along the transect. Observers traveled at a slow pace to increase the level of safety and to give ample time to scan the area for any potential goshawk or goshawk sign. On every third set of transects, all three observers would broadcast goshawk calls, using the same broadcasting procedure recommended in the “broadcast acoustic” survey protocol.

All goshawk sign encountered was analyzed and scrutinized in the field by a team of biologists. Any potential goshawk sign encountered would elicit an intensive search of the area by all biologists. The intensive search would cover an area of at least a 300 meter radius from the goshawk sign observed. All raptor feathers encountered were reviewed in the field and collected in case they needed further review in the lab. The “intensive search survey” methodology is time-consuming and physically demanding of
the biologists. The results however, give us a very high likelihood of detecting the presence of goshawks.

5. Survey Results

5.1. Northern Spotted Owl

Turnstone conducted two consecutive years of spotted owl surveys in 2008 and 2009 with a minimum of three site visits per calling station on and adjacent to SDS properties, (Appendix A). Two spotted owl activity centers located on public lands (WDNR, USFS) to the north of the project area were also surveyed. The Mill Creek (MSNO#: 0991) and Moss Creek (MSNO#: 1003) cores are located in Township 4N and Range 10E section 28 and Township 4N and Range 9E section 35, respectively. A total of 80 calling stations were established and surveyed in 2008 and 2009 with no northern spotted owl responses or observations. Seven supplemental stations were added in 2009 adjacent to areas that were determined to have potential habitat. There were no observations or detections of spotted owls at any of the 87 established calling stations in 2008 or 2009.

In 2008, Turnstone conducted an additional day visit to the two Moss and Mill Creek nest cores where spotted owls historically lived. No spotted owl observations or responses were recorded. In 2009, Turnstone added three additional day visits in addition to the required night visits to each nest core with no spotted owl observations or responses.

Tables 3A and 3B summarize all of the Turnstone survey response/observation results for the survey efforts in the 2008 and 2009 survey seasons. A map depicting the locations of the calling stations and locations of all barred owl responses/observations is available for review in Appendix A of this document.

Table 4A outlines the results of the northern spotted owl surveys at each of the two nest cores that intersect the project area. Results were derived from data collected by the WDNR southeast Washington NSO demography study and NACASI. The data shows no spotted owl detections in the Mill Creek core since the 2000 breeding season. The Moss Creek core has not had a spotted owl detected since the 2002 breeding season. Table 4B shows the results of the Turnstone survey effort at the two activity centers for the 2003, 2004, 2008 and 2009 survey seasons. Both cores show an increased presence of barred owls detected while conducting surveys for spotted owls.

### 5.2. Western Gray Squirrel

Western gray squirrel nest surveys were conducted in the fall of 2008 and again in the spring of 2009. These surveys constituted two complete rounds of survey covering all potential habitat within the survey polygons. The objective of this survey effort was to determine western gray squirrel use and/or sign of historical use on any potential habitat within the project buffers. A systematic nest search occurred on 26 polygons at the proposed energy project and 400 ft buffers into adjacent undisturbed suitable squirrel habitat (per WDFW protocol guidelines). No western gray squirrels or western gray squirrel nest structures were observed during the three site visits that occurred over two years.

5.3. Northern Goshawk

Turnstone conducted protocol northern goshawk surveys on SDS properties during the 2008 and 2009 goshawk survey windows. The survey protocol methodology used was the “broadcast acoustical survey” and “Intensive search survey” methodology, outlined in the protocol; “Northern Goshawk Inventory and Monitoring Technical Guide, USFS, July 2006.” Calling stations were strategically placed throughout the survey area in all suitable habitat within 2,624 feet (800 meters) of the turbine right of way. Turnstone completed two protocol site visits at 136 calling stations, using the “broadcast acoustic survey”, during the 2008 and 2009 goshawk survey seasons. One site visit was conducted during the nestling period and the second during the fledgling period as recommended in the protocol. No northern goshawk responses were documented during either of the two site visits in either the 2008 or 2009 survey seasons. Survey dates for the “broadcast acoustic” surveys and incidental raptor observations are summarized in Table 6A and 6B.

Table 6A. Northern Goshawk Broadcast Acoustic Survey Results Summary 2008.

Changes in the proposed alignment of the project area intersected additional goshawk habitat in October of 2008. These changes occurred after the goshawk survey window in 2008. In 2009, additional goshawk habitat was surveyed using a different survey methodology. The “Intensive search survey” methodology was used to survey approximately 389 acres in 2009. This survey effort involved two rounds of survey effort using a minimum of three biologists simultaneously. No northern goshawk responses or goshawk sign was documented during either of the two site visits.

Survey dates for the “intensive search survey” and incidental raptor observations are summarized in Table 6C. Maps of the survey areas for northern goshawks in 2008 and 2009 are available for review in Appendix A. Copies of the field data sheets for the 2009 survey effort are available for review in Appendix C.

6. CONCLUSION

6.1. Northern Spotted Owl

During the 2008 and 2009 Northern spotted owl survey seasons, Turnstone conducted six site visits to each of the established spotted owl calling points. A total of 80 calling stations were established and surveyed in 2008 and 2009. Seven supplemental stations were added in 2009 adjacent to areas that were determined to have potential habitat. There were no observations or detections of spotted owls at any of the calling stations in
2008 or 2009. Turnstone also conducted an additional day visit to both nest cores (Mill Creek, Moss Creek) in 2008. In 2009 three additional day visits up and beyond the required three night visits were conducted. These visits were spread strategically throughout the nesting season in an attempt to see or hear spotted owls. The survey effort covered potentially suitable northern spotted owl habitat within the approximately 22,123 acres of survey area. Turnstone recorded no northern spotted owl observations or responses during any of the 10 site visits.

6.2. Western Gray Squirrel

During the 2008 and 2009 western gray squirrel survey windows, Turnstone biologists conducted nest searches on 26 different polygons of potential western gray squirrel habitat. The first round of surveys occurred in the fall of 2008 with the second round soon to follow the spring of 2009. Approximately 738 acres of potential western gray squirrel habitat was surveyed in 2008 and 692 acres were surveyed in 2009. Turnstone biologists did not observe any Western gray squirrels or their nest structures during two site visits.

It should be noted that very few oak trees, a prime source of food for gray squirrels, were observed in the project area. The few that were observed within the western gray squirrel survey area boundaries were small (less than 20 feet tall), stunted, and growing in openings on exposed rocky slopes in shallow soils. Sources of year round water are also important to populations of western gray squirrels. There were few observed year round water sources with the exception of a few drainages and one wetland area.

6.3. Northern Goshawk

Turnstone conducted protocol northern goshawk surveys on SDS properties during the 2008 and 2009 goshawk survey windows. The survey protocol methodology used was the “broadcast acoustical survey” and “Intensive search survey” methodology, outlined in the protocol; “Northern Goshawk Inventory and Monitoring Technical Guide, USFS, July 2006.” Turnstone completed two protocol site visits at 136 calling stations, using the “broadcast acoustic survey”, during the 2008 and 2009 goshawk survey seasons. One
site visit was conducted during the nestling period and the second during the fledgling period as recommended in the protocol. No northern goshawk responses were documented during either of the two site visits.

The “Intensive search survey” methodology was used to survey approximately 389 acres on SDS and WDNR property. This survey effort involved two rounds of survey using three to four biologists simultaneously. No northern goshawk observations, responses or goshawk sign was documented during either of these two site visits.

### Comments:
- 32A: Incidental Station, called continuously on hike into Sta. 32/33 @ Desk, Visual Hike @ 1322.
- 45: Mixed spruce and aspen (no recent clear cut + BARK TRAP) stumps present.
- 48: Bird in tree just off road.
- 49: Bird in tree just off road.

**Block/Area ID:**

*Remarks: B is a map of where Sta. 32A was located.*

## Goshawk Survey Form

**Survey Time:** Start: __________ End: __________

**Intensive Nest Search Time:** Start: __________ End: __________

**Temperature (°F):** Begin: __________ End: __________

**Survey Area/Project Area:** Wrestling Ridge

**Period:** Nesting, Fledgling, Call(s) Used: Alarm / Call 1

**Survey Year:** 2009

**Survey Method:** Broadcast Acoustical, Intensive Search

**Weather Codes:**
- 1 = Light air (>1 mph)
- 2 = Light breeze (1-4 mph)
- 3 = Gentle breeze (4-7 mph)
- 4 = Light Wind (8-12 mph)
- 5 = Wind (12-15 mph)
- 6 = Gusty (>15 mph)

**Wind Codes:**
- A = Air
- C = Cloudy
- D = Drizzle
- R = Rain
- N = Snow

**Weather Intensity (WI):** 1 = Light, 2 = Moderate, 3 = Heavy

### Additional Notes
- **Age:** Adult (A), Juvenile (J), Immature (I), Unknown (U)
- **Sex:** Male (M), Female (F), Unknown (U)
- **Det. Code:** Acoustic (A), Visual (V), Both (B)
- **Location:** AT station, BT between stations
- **Det. ID:** Unique detection identifier, date and sequential det. # for the day, (061208-1, 061208-2, etc.)
- **Time:** Military format
- **Comments:** All 3 observers broadcast 2 miles @ 1-minute intervals
- **Plucking post:** 10 m from this point
- **Observation:** 3 goshawks observed, one was a juvenile, the other 2 were likely adults but observers were unable to determine for sure. Birds were observed 50 m outside of the survey polygon.

Appendix D - Western Gray Squirrel Survey Forms
WESTERN GRAY SQUIRREL SURVEY - COVER SHEET

Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. For each map, attach one Map Label and one or more Western Gray Squirrel Survey Data Sheets. If you see or hear a western gray squirrel please fill out a wildlife observation form and attach.

Mark Water Sources and Survey Transect or Survey Polygon on Attached Map.

Name of Area Surveyed: Polygons: A1, A2, B1, B2
(Use a generic geographic name like "Yahme Canyon". Add the timber sale name/number if available.)

Location (TRS): T 4N R 10E S 31
T 3N R 10E S 6
County: Skamania
County: Skamania
Date(s) Surveyed: 3/11/09
Start/Stop time(s): 0930-1215

Surveyor Names and Affiliations: D. Sahl, Turnstone Environmental Consultants

Contact Name, Address, & Phone:
TECI
Turnstone Environmental Consultants Inc.
18000 NW Lucy Reeder Rd Portland, OR 97231
503-621-9613

Directions to Site: Be specific enough to allow someone unfamiliar with the site to find it.
From the Jct. of Cook Underwood Rd. and Knapp Rd. Go NW on Knapp Rd. for ~0.1 miles to Scoggins Rd., Turn right onto Scoggins Rd. and ~100 yards to Jct. with private drive on left (Signed as CG 2930). Proceed up CG 2930 to access SDS and WDNR lands. See the polygon map for access routed to the specific survey polygons.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.
All polygons surveyed were composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSH. The majority of the overstory PSME appears to be >25 years of age, with some scattered remnant PSME >70 years. Slopes within the polygon boundaries vary between ~0% to 30%. The aspect of each polygon also varies. The A1, A2, B1 and B2 polygons have a predominantly southern aspect. No areas of standing water were observed in any of the polygons during the survey. Most areas within the survey polygon had some snow cover varying from a trace to several feet in depth at the time of the survey.

No Western Gray squirrels, or their nest structures were observed during the survey. Several bird nests were observed and numerous Douglas squirrels were heard and a few were observed. Several Rabbits were observed in the A2 polygon.
Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. For each map, attach one Map Label and one or more Western Gray Squirrel Survey Data Sheets. If you see or hear a western gray squirrel please fill out a wildlife observation form and attach.

Mark Water Sources and Survey Transect or Survey Polygon on Attached Map.

From the Jct. of Cook Underwood Rd. and Knapp Rd. Go NW on Knapp Rd. for ~0.1 miles to Scoggins Rd. Turn right onto Scoggins Rd. and go ~100 yards to Jct. with private drive on left (Signed as CG 2930). Proceed up CG 2930 to access SDS and WDNR lands. See the polygon map for access routes to the specific survey polygons.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.
All polygons surveyed were composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSH. The majority of the overstory PSME appears to be >15 years of age, with some scattered remnant PSME >70 years. A few small patches of Quercus SPP (likely Quercus Garryana), were observed within the boundaries of the A3 polygon. The trees were not > than 15ft. in height and growing in a few steep, rocky, open areas with a westerly aspect. In Polygons A3 there were numerous ACMA and ACCI present, especially towards the toe of the slope and along drainages. Slopes within the polygon boundary vary but are generally steep, with a few rocky cliff areas, between ~0% to 85%. The A3 polygon has a predominantly western aspect and several active incised drainages. Water was present in seasonally intermittent streams in polygon A3 on the north end of the polygon at the time of survey. No areas of non-flowing, standing water were observed in the polygon during the survey. Most areas within the survey polygon had some snow cover varying from a trace to several feet in depth at the time of the survey.

No Western Gray squirrels, or their nest structures were observed during the survey. Numerous douglas squirrels were heard and a few were observed. Recent Bract piles were observed in several locations all were presumed to be created by douglas squirrels.
WESTERN GRAY SQUIRREL SURVEY - COVER SHEET

Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. For each map, attach one Map Label and one or more Western Gray Squirrel Survey Data Sheets. If you see or hear a western gray squirrel please fill out a wildlife observation form and attach.

Proceed up CG 2930 to access SDS and WDNR lands. See the polygon map for access routed to the specific survey polygons.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, end distance to nearest water.

Both polygons surveyed were composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/THSE. The majority of the overstory PSME appears to be >25 years of age, with some scattered remnant PSME >70 years. No patches of Quercus SPP. were observed within the boundaries of the A5 or B5 polygons. In both Polygons there were ACMA present. Slopes within the polygon boundaries vary between ~0% to 30%. Both polygons have predominantly north to NNE aspects. Their was a small section of active drainage in B5. Most areas within the survey polygon had some snow cover varying from a trace to several feet in depth at the time of the survey.

No Western Gray squirrels, or their nest structures were observed during the survey. Numerous douglas squirrels were heard and observed.
Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. For each map, attach one Map Label and one or more Western Gray Squirrel Survey Data Sheets. If you see or hear a western gray squirrel please fill out a wildlife observation form and attach.

From the Jct. of Cook Underwood Rd. and Knapp Rd. Go NW on Knapp Rd. for ~0.1 miles to Scoggins Rd., Turn right onto Scoggins Rd. and ~100 yards to Jct. with private drive on left (Signed as CG 2930). Proceed up CG 2930 to access SDS and WDNR lands. See the polygon map for access routed to the specific survey polygons.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, end distance to nearest water.
Both polygons surveyed were composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSE. The majority of the overstory PSME appears to be >25 years of age, with some scattered remnant PSME >70 years. No patches of Quercus SPP. were observed within the boundaries of the A6 or B4 polygons. In both Polygons there were ACMA present. Slopes within the polygon boundaries vary between ~0% to ~45%. The A6 polygon has a predominantly southwestern aspect, the B4 polygon has several aspects that include: NW, NE and S. Both polygons had had active drainages. Their were 2 small active drainages in B4 and a larger active drainage and a pond in the A6 polygon. Most areas within the survey polygon had some snow cover varying from a trace to several feet in depth at the time of the survey. The pond that was present in A6 was roundish in shape and appeared to be shallow (>10' deep and ~50 feet across at time of survey), it was difficult to determine the exact extent of the pond area due to the snowpack. Water in the pond is present year round as observed in mid August of this year. No Western Gray squirrels, or their nest structures were observed during the survey. Numerous douglas squirrels were heard and observed. Several large bract piles were encountered in the A6 polygon which were attributed to the douglas squirrels observed. A coyote was also observed on the edge of the A6 polygon.
Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. For each map, attach one Map Label and one or more Western Gray Squirrel Survey Data Sheets. If you see or hear a western gray squirrel please fill out a wildlife observation form and attach.

Mark Water Sources and Survey Transect or Survey Polygon on Attached Map.

Proceed up CG 2930 to access SDS and WDNR lands. See the polygon map for access routes to the specific survey polygons.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.

The A10 and A9 polygons were surveyed in a leapfrog fashion by 3 surveyors walking adjacent meandering transects. The A10 and A9 polygons are composed of mixed conifer/hardwoods, primarily PSME with some scattered TSHE. The majority of the overstory in the stands in these polygons was PSME and appears to be mixed age, most was >20 years of age with a few older remnant trees present. No patches of Quercus spp. were observed within the boundaries of the polygons. Both polygons are fairly flat with slopes within the polygon boundaries that vary between ~0% to 5%
There were no drainages or areas of standing water present within the polygons. Most areas within the survey polygon had some snow cover varying from a trace to several feet in depth at the time of the survey.

No Western Gray squirrels, or their nest structures were observed during the survey. numerous douglas squirrels were heard and a few were observed. Bract piles were observed in several areas within the survey polygons, they were attributed to the numerous douglas squirrels observed during the survey.

Proceed up CG 2930 to access SDS and WDNR lands. See the polygon map for access routes to the specific survey polygons.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, end distance to nearest water.

The A12 and A13 polygons were composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSH. The majority of the overstory in the stands in these polygons was PSME and appears to be mixed age, most was >20 years of age with a few older remnant trees present. No patches of Quercus spp. were observed within the boundaries of the polygons. Both polygons are very flat with slopes within the polygon boundaries vary between ~0% to 5%. Both polygons had very marginal potential WGS habitat. There were no drainage or areas of standing water present within the polygons. The A14 polygon was composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSH. The majority of the overstory PSME appears to be >25 years of age, stand appeared to be even aged. No patches of Quercus spp. were observed within the boundaries of the polygon. There was some ACMA and ACCL present within the polygon. Slopes within the polygon boundaries vary between ~0% to 60%. The A14 polygon has a westerly aspect and one seasonal drainage. The drainage was dry at the time of the survey. No areas of non-flowing, standing water were observed in the polygon during the survey. Most areas within the survey polygon had some snow cover varying from a trace to several feet in depth at the time of the survey. No Western Gray squirrels, or their nest structures were observed during the survey. Numerous Douglas squirrels were heard and a few were observed.
USE ONE COVER SHEET PER STAND SURVEYED. ATTACH THE MAP(S) ON WHICH YOU MARK SQUIRREL NESTS AND SHOW THE TRANSECT(S) OR AREA(S) SURVEYED. FOR EACH MAP, ATTACH ONE MAP LABEL AND ONE OR MORE WESTERN GRAY SQUIRREL SURVEY DATA SHEETS. IF YOU SEE OR HEAR A WESTERN GRAY SQUIRREL PLEASE FILL OUT A WILDLIFE OBSERVATION FORM AND ATTACH.

**DIRECTIONS TO SITE:** Be specific enough to allow someone unfamiliar with the site to find it.
From the Jct. of Cook Underwood Rd. and Knapp Rd. Go NW on Knapp Rd. for ~0.1 miles to Scoggins Rd. Turn right onto Scoggins Rd. and go ~100 yards to Jct. with private drive on left (Signed as CG 2930). Proceed up CG 2930 to access SDS and WIDNR lands. See the polygon map for access routes to the specific survey polygons.

**DESCRIPTION OF HABITAT AT SITE:** Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.

The A19, A17, B6, B7, B8 and C1 polygons were surveyed by 3 surveyors walking concurrent, adjacent meandering transects. All of the survey polygons are along the top or flanks of a ridge running almost north/south. The B8, B7 and B8 polygons are small extension of the A17 and A18 polygons that were added to the survey area after the the boundaries of the original polygons were determined. The habitat type in the B polygons is similar to their adjacent A polygon. The survey polygons are composed of mixed conifer/hardwoods, primarily PSME with some scattered TSHE and THPL in the drainages. The majority of the overstory in the stands in these polygons was PSME and appears to be mixed age, most was >20 years of age. A few scattered remnant trees older than 70 years were present. No patches of Quercus spp. were observed within the boundaries of the polygons. There were some areas ACMA and ACCI present within the polygons. All of these polygons were on the extreme southern end of the project area. A18 has a northwestern aspect on a fairly steep slope and a seasonal drainage that was wet and flowing at the time of the survey.

The A17 polygon had a south and southeast exposure and no significant drainages. It did not host trees older than the other polygons in the overstory and a few remnant PSME present that were greater than 70 yrs of age. The A17 polygon is adjacent to the C1 polygon that had a seasonal stream present in it that was flowing at the time of survey but was obscured due to snowpack in most places. The C1 polygon had a SW aspect. Slopes within the polygon boundaries vary between ~10% to 80%. Most areas within the survey polygon had some snow cover varying from a trace to several feet in depth at the time of the survey.

No Western Gray squirrels, or their nest structures were observed during the survey. numerous douglas squirrels were heard and a few were observed.
WESTERN GRAY SQUIRREL SURVEY - COVER SHEET

Proceed up CG 2930 to access SDS and WDNR lands. See the polygon map for access routes to the specific survey polygons.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.

The A7 polygon surveyed was composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSE. The majority of the overstory PSME appears to be >20 years of age, with some scattered remnant PSME >70 years. Some areas of this polygon had large amounts of vine maple. Slopes within the polygon boundary vary between ~0% to 40%. The A7 polygon has a variety of aspects, primarily eastern and northern. Water was present in 2 streams in the polygon. one stream appears to be seasonally intermittent and the other appears to have some water present all season (as observed while conducting other surveys in july/august). Both contained water at time of survey, stream banks indicate that the water level increases significantly during the wet season. No areas of non-flowing standing water were observed in the A7 polygon. Most areas within the survey polygon had some snow cover varying from a trace to several feet in depth at the time of the survey.

No Western Gray squirrels, or their nest structures were observed during the survey. numerous douglas squirrels were heard and a few were observed. Recent Bract piles were observed in several locations all were presumed to be created by douglas squirrels.
Use one cover sheet per stand surveyed. Attach the map(s) on which you mark squirrel nests and show the transect(s) or area(s) surveyed. Proceed up CG 2930 to access SDS and WDNR lands. See the polygon map for access routed to the specific survey polygons.

Description of Habitat at Site: Include approximate age/size (dbh) of stand, dominant overstory species, percent oak in stand, slope position and aspect, and distance to nearest water.
This polygon was surveyed by 3 surveyors simultaneously. The polygon is composed of mixed conifer/hardwoods, primarily PSME with some scattered THPL/TSHE. The majority of the overstory PSME appears to be >30 years of age, with some scattered remnant PSME >60 years. No patches of Quercus SPP. were observed within the boundaries of the polygon. In Scattered ACMA was present throughout the polygon. Slopes within the polygon boundaries vary between ~0% to 70%. The polygon has a predominant north to NE aspect. Their were a few seep areas that appeared to be active seasonally in the bottom of a few of the small drainages present in the polygon. Most areas within the survey polygon had some snow cover varying from a trace to several feet in depth at the time of the survey.

No Western Gray squirrels, or their nest structures were observed during the survey. Several douglas squirrels were heard and observed while surveying the polygon.

EXECUTIVE SUMMARY

In August 2007 Western EcoSystems Technology, Inc. initiated surveys designed to assess bat use within the proposed Saddleback Wind Energy Project, Skamania County, Washington. Passive AnaBat® II echolocation detectors were used to perform acoustic surveys for bats from August 20 through October 21, 2007. Three survey stations were established in the study area and each Anabat surveyed continuously during the night time hours over the study period.

The objective of the acoustic bat surveys was to estimate the seasonal and spatial use of the study area by bats. Two Anabat echolocation detectors were used to periodically monitor bat use at the study during the period August 20 - October 21, 2007. A total of 348 bat passes were recorded during 45 detector nights. Just over half (55%) of the calls were < 35 kHz in frequency (e.g., big brown bat, hoary bat), and the remaining calls were > 35 kHz (e.g., Myotis bat species). Species identification was only possible for the hoary bat, which made up 5% of all passes. Activity levels for bat passes peaked in late August/early September. Activity levels for hoary bats were highest in mid-September, suggesting this species migrates through the study area at this time of year. However, equipment failures prevented data collection between September 17 and October 14, so bat activity during this period is unknown.

The mean number of bat passes per detector per night was compared to existing data at five wind-energy facilities where both bat activity and mortality levels have been measured. The level of bat activity documented at the Saddleback Wind Resource Area was higher than that at wind-energy facilities in Minnesota and Wyoming, where reported bat mortalities are low, but was much lower than at facilities in the eastern US, where reported bat mortality is highest. Based on the available data it is likely that some bat mortality will occur in the study area, but the mortality is not expected to be as high as other facilities, and most casualties may occur late-August to mid-September, during likely migration periods. Assuming that a relationship between bat activity and bat mortality exists, and that it extends to the western US, the rate of bat mortality at the Saddleback Wind Resource Area would likely be greater than the 2.2 bat fatalities/turbine/year reported at the wind-energy facility at Buffalo Ridge, Minnesota, and would likely be much lower than the 20.8 fatalities/turbine/year reported at the facility at Buffalo Mountain, Tennessee.

INTRODUCTION

SDS Lumber Company is proposing to develop a wind-energy facility, the Saddleback Wind Energy Project (SWRA), in Skamania County, Washington (Figure 1). SDS Lumber requested Western EcoSystems Technology, Inc. (WEST) to develop and implement a standardized protocol for baseline studies of bat use in the project area for the purpose of estimating the impacts of the wind-energy facility on bats, and to assist with siting turbines to minimize impacts to bats. The protocol for the baseline study is similar to protocols used at other wind-energy facilities in the US. The protocol has been developed based on WEST’s experience studying wildlife and wind turbines at projects throughout the US and included passive AnaBat® II (Anabat) ultrasonic detectors sampling from fixed stations to quantify bat use in the study area.

The purpose of this report is to summarize and describe the results of Anabat surveys during the fall of 2007, and to bring any items of biological interest, such as changes in seasonal bat use, to the attention of SDS Lumber. The scope of the surveys for bats included only acoustic bat surveys at fixed stations.

STUDY AREA

The proposed project area is in southeast Skamania County, approximately four miles northwest of White Salmon, Washington (Figure 1). The specific project area is just north of Underwood Mountain and includes Sections 5, 6, 7, and 8, Township 3N, Range 10E. The project area consists of hilltops, dominated by coniferous forests with some clearcuts, and linear clearings associated with powerline rights-of-way. Elevation of the project area ranges from approximately 1,700 – 2,400 feet (ft; 518 – 732 meters (m)) above sea level.

METHODS

The objective of the acoustic bat surveys was to estimate the seasonal and spatial use of the SWRA by bats. Bats were surveyed using AnaBat® II ultrasonic detectors coupled with Zero Crossing Analysis Interface Modules (ZCAIM; Titley Electronics Pty Ltd., NSW, Australia). Bat detectors are widely used to index and compare habitat use by bats. The use of bat detectors for calculating an index to bat impacts has been used at several wind-energy facilities (Kunz et al. 2007a), and is a primary and economically feasible bat risk assessment tool (Arnett 2007). Bat activity was surveyed using two detectors from August 20 to October 21, 2007, a period corresponding to likely fall bat migration at this site.

Detectors were placed at two locations (Figure 1). The detector at the north location was placed on the ground at the base of a meteorological tower on August 20, but on September 7 was elevated on the tower at a height of approximately 130 ft (40 m). The detector at the south location was placed on the ground on September 7, and remained there for the duration of the study. It was placed just outside the project area, but in an area representative of the project area in terms of habitat and topography.
Anabat detectors record bat echolocation calls with a broadband microphone. The echolocation sounds are then translated into frequencies audible to humans by dividing the frequencies by a predetermined ratio. A division ratio of eight was used for the study. Bat echolocation detectors also detect other ultrasonic sounds made by insects, raindrops hitting vegetation, and other sources. A sensitivity level of six was used to reduce interference from these other sources of ultrasonic noise. The calls were recorded via the ZCAIM, which uses a CompactFlash memory card with large storage capacity. The Anabat detectors were placed inside weather-tight containers (plastic tubs for ground units, a polypropylene dry bag for the elevated unit) with a hole cut in the side of the container for the microphone to extend through. Microphones were encased in PVC tubing with drain holes that curved vertically outside the container to minimize the potential for water damage due to weather. Anabat units situated on the ground were raised approximately 3 ft (1 m) to minimize echo interference and to elevate the unit above vegetation. The elevated Anabat unit was raised approximately 130 ft (40 m) up the meteorological tower using a pulley system. All units were programmed to turn on approximately ½ hour before sunset and turn off approximately ½ hour after sunrise each night.

Incoming echolocation calls were digitally processed by the detector and passed to the ZCAIM for further processing and data storage. Each series of echolocation calls was saved to a file on a high-capacity CompacFlash card, and these files were then transferred to a computer for analysis. Computer software was used to view digital “sonograms” of the echolocation calls showing change in frequency over time. During analysis, these frequency versus time displays were used to separate bat calls from other types of ultrasonic noise (e.g. wind, rain, insects, etc.) and to assign calls to a high- or low-frequency group.

The units of activity were number of bat passes (Hayes 1997). The absolute abundance of bats within a study area cannot be determined through acoustic sampling, and bat pass data represent levels of bat activity rather than numbers of individuals. A pass was defined as a continuous series of two or more call notes produced by an individual bat, with no pauses between call notes of more than one second (White and Gehrt 2001; Gannon et al. 2003). In this report, the terms bat pass and bat call are used interchangeably. The number of bat passes was determined by downloading the data files to a computer and tallying the number of echolocation passes recorded. Total number of passes was corrected for effort by dividing by the number of detector nights. Bat passes were classified as either high-frequency calls (≥ 35 kHz), which are generally given by small bats (e.g. Myotis spp. and western red bat (Lasiurus blossevillii)), or low-frequency (< 35 kHz), which are generally given by larger bats (e.g. Townsend’s big-eared bat (Corynorhinus townsendii), and hoary bat (Lasiurus cinereus)). Data determined to be noise (produced by a source other than a bat) or call notes that did not meet the pre-specified criteria to be termed a pass were removed from the analysis. To establish which species may have produced the high- and low-frequency calls recorded, a list of species expected to occur in the study area was compiled from range maps (Harvey et al. 1999; BCI website).

The total number of bat passes per detector night was used as an index for bat use at the SWRA. Bat pass data represent levels of bat activity, rather than the numbers of individuals present, because individuals cannot be differentiated by their calls. Bat activity was summarized by location and by weekly and nightly intervals from August 20 to October 21, 2007. To predict potential for bat mortality (i.e. low, moderate, high), the mean number of bat passes per detector...
night across locations (i.e., the mean of ratios) was compared to existing data from wind-energy facilities where both bat activity and mortality levels have been measured.

RESULTS

Bat activity was monitored at three sampling locations on a total of 63 nights during the period August 20 – October 21, 2007. Equipment failures compromised data collection for the northern unit between September 17 and October 14, and for the southern unit between September 17 and October 21. Anabat units were operable for 24% of the sampling period, recording 348 bat passes on 45 detector-nights (Table 1). Averaging bat passes per detector-night across locations gave a mean of 7.91 bat passes per detector-night.

Spatial Variation

Bat activity was similar between the ground Anabat units in the north (mean = 11.67 ± 2.0 bat passes per detector-night) and south (mean = 9.60 ± 4.1; Figure 2a) locations. At both locations, the number of high-frequency (HF) bat passes per detector-night was approximately one and a half times greater than the number of low-frequency (LF) passes. Bat activity was much lower at the north elevated location (mean = 2.47 ± 1.1), and LF bat passes greatly outnumbered HF bat passes. Patterns of nightly activity were similar among detector locations (Figure 2b), although data from the north ground detector were not collected concurrently with data from the other two detectors, making direct comparisons difficult.

Seasonal Variation

From the start of the acoustic bat surveys on August 20, bat activity increased to a peak on September 1, and then decreased through September 13, 2007 (Figure 3). Bat detectors were largely inoperable past September 17, preventing detection of bats for the entire duration of the study, except for a one-week period at the end of the study for the north elevated station, during which no bats were detected. Patterns of activity for HF and LF bats were congruent with the overall trend (Figure 4a), with the number of HF bat passes per detector-night peaking between August 30 and September 1 (26% of all HF passes), and LF bat activity at its highest on September 6 and 9 (29% of all LF passes; Figure 4b).

Species Composition

Species identification for specific bat passes was possible for the hoary bat; therefore, passes by this species could be separated from passes by all other low-frequency bats. Hoary bats comprised 5.7% of the total passes detected within the SWRA (20 of 348 bat passes; Table 1). Most passes by hoary bats occurred at the south location (mean = 1.2 ± 0.7 passes per detector-night), with several being detected at the north elevated location (mean = 0.2 ± 0.1) as well. No hoary bat passes were detected at the north ground location. Activity for hoary bats was highest on September 9 (44% of total hoary passes; Figure 5).
DISCUSSION

Potential Impacts

Assessing the potential impacts of wind energy development to bats at the SWRA is complicated by our current lack of understanding of why bats collide with wind turbines (Kunz et al. 2007b), combined with the inherent difficulties of monitoring elusive, night-flying animals (O’Shea et al. 2003). To date, monitoring studies of wind-energy facilities suggest that a) migratory tree-roosting species (eastern red bat (*Lasiurus borealis*), hoary bat, and silver-haired bat (*Lasionycteris noctivagans*)) comprise almost 75% of reported bats killed (Kunz et al. 2007b); b) the majority of collisions occur during the post-breeding or fall migration season (roughly August and September; Gruver 2002; Johnson et al. 2003); and c) the highest reported fatalities occur at wind facilities located along forested ridge tops in the eastern US (Kunz et al. 2007b), although recent studies report relatively high fatalities as well in agricultural regions of Iowa (Jain 2005) and Alberta, Canada (Baerwald 2006).

Some studies at wind-energy facilities have recorded both pre-construction Anabat detections per night and bat mortality once the facility is operational (Table 2). The number of bat calls per night as determined from bat detectors shows a rough correlation with bat mortality, but may be misleading because effort, timing of sampling, species recorded, and detector settings (equipment and locations) varies among studies (Kunz et al. 2007b). The best available estimate of mortality levels at a proposed wind-energy facility involves the evaluation of on-site acoustic bat data, in terms of activity levels, seasonal variation, and species composition, and the topographic features of the project area.

Activity

Bat activity at the SWRA (mean = 7.91 bat passes per detector-night; Table 1) was relatively high compared to that observed at wind-energy facilities in Minnesota and Wyoming, where bat collision mortality was low, but it was much lower than activity recorded at facilities in West Virginia and Tennessee, where bat mortality rates were high (Table 2). Based on the presumed relationship between pre-construction bat activity and post-construction fatalities, we expect bat mortality rates at the SWRA to be greater than the 2.2 bat fatalities/turbine/year reported at Buffalo Ridge, Minnesota, but much lower than the 20.8 fatalities/turbine/year reported at Buffalo Mountain, Tennessee.

Seasonal Variation

The number of bat calls detected per night at the SWRA peaked in late-August/early-September. Activity by hoary bats appeared to peak in mid-September, suggesting that migration of this species through the area occurs at this time of year. However, given the lack of Anabat coverage between September 17 and October 14, it is unknown whether bat activity would continue to abate, or whether subsequent pulses of activity were missed. The absence of bat calls from the detector at the north elevated station between October 15 and 21 suggests that bat activity is low at this time of year. Fatality studies of bats at wind-energy facilities in the US have shown a peak in mortality in August and September, and generally lower mortality earlier in the summer.
(Johnson 2005). While survey efforts vary among different studies, the studies that combine Anabat surveys and fatality surveys show a general association between the timing of increased bat call rates and timing of mortality, with both call rates and mortality peaking during the fall (Kunz et al. 2007b). Based on the available data, it is expected that bat mortality at the SWRA will be highest in late August/early September, with an undetermined potential for mortality in late September/early October.

**Species Composition**

Of the fourteen species of bat likely to occur in the study area, five are known fatalities at wind-energy facilities (Table 3). Acoustic bat surveys were unable to determine bat species present in the study area (except for hoary bat), but they were able to distinguish high-frequency from low-frequency species. Bat passes at the SWRA were fairly evenly distributed between high- and low-frequency species. Fifty-five percent of passes were by high-frequency bats, suggesting higher relative abundance of species such as western red bat and *Myotis* species. High-frequency species were detected more often than low-frequency species at the ground stations, whereas the reverse was true at the north elevated station. This pattern may reflect different foraging strategies among species. Many of the low-frequency species likely to be present at the SWRA (e.g., hoary bat, silver-haired bat, and big brown bat (*Eptesicus fuscus*)) tend to forage at higher altitudes than most high-frequency species, due to their wing morphology and echolocation call structure (Norberg and Rayner 1987). Hoary bats made up 10% of all low-frequency passes at the SWRA, and were most active in mid-September, suggesting fall migration through the area.

EXECUTIVE SUMMARY

Western EcoSystems Technology, Inc. initiated surveys in July 2008 designed to assess bat use within the proposed Saddleback Wind Resource Area, Skamania County, Washington. Acoustic surveys for bats using Anabat® SD-1 ultrasonic detectors at four fixed stations were conducted from July 3 to October 7, 2008. The objective of the acoustic bat surveys was to estimate the seasonal and spatial use of the study area by bats. A total of 56,595 bat passes were recorded during 97 detector nights. Averaging bat passes per detector-night across locations, we detected a mean of 148.34 bat passes per detector-night across all stations.

Three stations were placed in upland areas typical of those likely to contain wind turbines. Data from these three detectors were used to assess risk of bat collision mortality. A fourth detector was placed adjacent to a pond in the local area to assess levels bat activity and composition of primarily breeding bats in the project area.

At the three upland stations, over 65% of the calls were <35 kHz in frequency (e.g., big brown bat, silver-haired bat, hoary bat), and the remaining calls were >35 kHz (e.g., Myotis bat species). Species identification was only possible for the hoary bat, which made up 6.0% of all passes at the upland stations. At the wetland station (SB2), 69.7% of all passes were >35 kHz and hoary bats composed 2.0% of all recorded bat passes. Activity levels for bat passes both the upland stations and wetland station peaked in July and early August. Activity levels for hoary bats were highest in July, suggesting the project area is used more for breeding by this species than as a migration corridor.

The mean number of bat passes per detector per night was compared to existing data at five wind-energy facilities where both bat activity and mortality levels have been measured. The level of bat activity documented at the Saddleback Wind Resource Area was considerably higher than that at wind facilities in Minnesota and Wyoming, where reported bat mortalities are low, and was also higher than at facilities in the eastern US, where reported bat mortality is highest.

Although high bat activity levels were recorded at the Saddleback Wind Resource Area, the available evidence indicates that these data do not necessarily imply that bat fatality levels will be high. Numerous factors, including the timing of the activity, differences in call rates among the various habitats, and composition of the bat calls suggest that bat mortality may be lower than indicated by the high bat activity recorded. No data on bat mortality levels associated with wind energy developments in western coniferous forests are available to help predict risk to bats at the Saddleback Wind Resource Area. Bat fatality patterns may differ from those in open habitats as well as in eastern deciduous forests.

INTRODUCTION

SDS Lumber Company is proposing to develop a wind-energy facility in Skamania County, Washington. SDS Lumber requested Western EcoSystems Technology, Inc. (WEST) to develop and implement a standardized protocol for baseline studies of bat use in the project area for the purpose of estimating the impacts of the wind-energy facility on bats, and to assist with siting turbines to minimize impacts to bats. The protocol for the baseline study is similar to protocols used at other wind-energy facilities in the United States. The protocol has been developed based on WEST’s experience studying wildlife and wind turbines at projects throughout the US and included passive acoustic sampling using Anabat bat detectors at fixed stations to quantify bat use in the study area.

STUDY AREA

The proposed project area is in southeast Skamania County approximately four miles northwest of White Salmon, Washington (Figure 1). The specific project area is just north of Underwood Mountain and includes Sections 5, 6, 7, & 8, Township 3N, Range 10E. The project area consists of hilltops dominated by coniferous forests with some clearcuts and linear clearings associated with powerline rights-of-way. Elevation of the project area ranges from approximately 1700′ – 2400′.

METHODS

Bat Acoustic Surveys

The objective of the bat use surveys was to estimate the seasonal and spatial use of the SWRA by bats. Bats were surveyed using Anabat® SD-1 bat detectors (Titley Electronics Pty Ltd., NSW, Australia). Bat detectors are a recommended method to index and compare habitat use by bats. The use of bat detectors for calculating an index to bat impacts has been used at several wind-energy facilities (Kunz et al. 2007), and is a primary and economically feasible bat risk assessment tool (Arnett 2007). Bat activity was surveyed using four detectors from July 3 to October 7, 2008, a period corresponding to summer breeding and fall bat migration at this site. Detectors were placed at four locations (Figure 1).

One detector (SB2) was placed at a wetland in the project area to assess activity levels and composition of local, breeding bats in the project area. This is a standard practice for evaluating local bat use of a project area when bat concentration areas such as wetlands or ponds are present. These data were not, however, used to assess risk to bats of collision mortality. The other three detectors were placed in upland areas typical of proposed turbine locations in the project area. One of these detectors (SB3) was placed at a linear clearing created for a road through coniferous forest, and the other two (SB1 and SB4) were placed within clear cuts in the project area.

Anabat detectors record bat echolocation calls with a broadband microphone. The echolocation sounds are then translated into frequencies audible to humans by dividing the frequencies by a
A predetermined ratio. A division ratio of 16 was used for the study. Bat echolocation detectors also detect other ultrasonic sounds made by insects, raindrops hitting vegetation, and other sources. A sensitivity level of six was used to reduce interference from these other sources of ultrasonic noise. Calls were recorded to a compact flash memory card with large storage capacity. The Anabat detectors were placed inside plastic weather-tight containers with a hole cut in the side of the container for the microphone to extend through. Microphones were encased in PVC tubing with drain holes that curved skyward at 45 degrees outside the container to minimize the potential for water damage due to rain. Containers were raised approximately 1 m off the ground to minimize echo interference and lift the unit above vegetation. All units were programmed to turn on each night approximately one half-hour before sunset and to turn off approximately one half-hour after sunrise.

**Statistical Analysis**

**Bat Acoustic Surveys**

The units of activity were number of bat passes (Hayes, 1997). A pass was defined as a continuous series of less than or equal to two call notes produced by an individual bat with no pauses between call notes of less than one second (White and Gehrt 2001, Gannon et al. 2003). In this report, the terms bat pass and bat call are used interchangeably. The number of bat passes was determined by downloading the data files to a computer and tallying the number of echolocation passes recorded. Total number of passes was corrected for effort by dividing by the number of detector nights. Bat calls were classified as either high-frequency calls (≥ 35 kHz) that are generally given by small bats (e.g. *Myotis* spp.) or low-frequency calls (< 35 kHz) that are generally given by larger bats (e.g. silver-haired bat (*Lasionycteris noctivagans*), big brown bat (*Eptesicus fuscus*), hoary bat (*Lasiurus cinereus*)). Data determined to be noise (produced by a source other than a bat) or call notes that did not meet the pre-specified criteria to be termed a pass were removed from the analysis. To establish which species may have produced the high- and low-frequency calls recorded, a list of species expected to occur in the study area was compiled from range maps (Table 1; Harvey et al. 1999, BCI website).

The total number of bat passes per detector night was used as an index of bat use in the SWRA. Bat pass data represented levels of bat activity rather than the numbers of individuals present because individuals could not be differentiated by their calls. To predict potential for bat mortality (i.e. low, moderate, high), the mean number of bat passes per detector night (averaged across those monitoring stations placed in upland habitats) was compared to existing data from wind-energy facilities where both bat activity and mortality levels have been measured.

**RESULTS**

**Bat Acoustic Surveys**

For the combined upland locations, bat activity was monitored at three sampling locations over a total of 97 nights during the period July 3 to October 7, 2008. Anabat units were operable for 95.5% of the sampling period (Figure 2), recording 39,326 bat passes on 278 detector-nights (Table 2). Bat activity at the wetland location (SB2) was also monitored for a total of 97 nights.
during the period of July 3 to October 7, 2008. This unit was operable for 100% of the sample period (Figure 3), recording 17,269 bat passes on 97 detector nights (Table 3). Averaging bat passes per detector-night across the upland locations (SB1, SB3, and SB4), we detected a mean of 138.44 bat passes per detector-night. The wetland station (SB2) recorded an average of 178.03 bat passes per detector-night.

Spatial Variation

Bat activity varied among upland Anabat units SB1, SB3 and SB4 in the SWRA (mean = 138.44 bat passes per detector-night; Figures 1, 4). A total of 80.7% of all bat passes (mean = 327.25 bat passes per detector-night) was recorded at station SB3, located along a linear clearing in a forested situation, while activity recorded at stations SB1 and SB4, located in clear cuts, comprised only 19.1% of all bat passes (mean = 14.30 and 73.76, respectively). AnaBat wetland station SB2 recorded a mean of 178.03 bat passes per detector-night (Figures 1, 5).

Temporal Variation

Bat activity was highest at the three upland stations throughout the months of July and August, with peak activity occurring between July 10 and July 16 (Figure 6). The greatest activity on a single night occurred on August 4 (1,445 passes). After the third week of August, activity dropped off to much lower levels and remained low for the duration of the study period. Temporal patterns were largely consistent among stations SB3 (road clearing) and SB4 (clear-cut), although SB3 recorded much greater levels of bat activity (Figure 6). The level of bat activity at station SB1 (clear-cut) was relatively consistent across the entire study period. Bat activity at wetland station SB2 was highest during the month of July (Figure 7), with an activity peak on July 5. Bat activity from July 3 through mid-August (mean = 218.6/detector night) was over four times higher than activity from mid-August through October 7 (mean = 52.3; Figures 10 and 11).

Species Composition

At the combined upland stations, passes by low-frequency bats (LF; 67.0%) outnumbered passes by high-frequency bats (HF; 33.0%). The proportion of HF and LF bat passes was similar among Anabat stations (Figure 8). At wetland station SB2, passes by HF bats (69.7%) outnumbered passes by LF bats (30.3%; Figure 9).

Species identification for specific passes was possible only for the hoary bat; therefore, passes by this species could be separated from passes by other low-frequency bats. Hoary bats comprised 6.0% of total passes detected at the combined upland points, and use among the three stations was similar (Figure 12). Hoary bats comprised 2.0% of total bat passes at the wetland station SB2 (Figure 13). Patterns of hoary bat activity were similar to other bats, with most bat passes occurring in July and early August (Figures 14 and 15).
DISCUSSION

Potential Impacts

Assessing the potential impacts of wind energy development to bats at the SWRA is complicated by our current lack of understanding of why bats die at wind turbines (Kunz et al. 2007b; Baerwald et al. 2008), combined with the inherent difficulties of monitoring elusive, night-flying animals (O’Shea et al. 2003). To date, monitoring studies of wind projects suggest that a) migratory tree-roosting species (eastern red, hoary, and silver-haired bats) comprise almost 75% of reported bats killed, b) the majority of fatalities occur during the post-breeding or fall migration season (roughly August and September), and c) the highest reported fatalities occur at wind facilities located along forested ridge tops in the eastern US (Arnett et al. 2008, Gruver 2002, Johnson et al. 2003, Kunz et al. 2007b), although recent studies in agricultural regions of Iowa and Alberta, Canada, report relatively high fatalities as well (Jain 2005, Baerwald 2006).

Some studies of wind projects have recorded both Anabat detections per night and bat mortality (Tables 4 and 5). The number of bat calls per night as determined from bat detectors shows a rough correlation with bat mortality, but may be misleading because effort, timing of sampling, species recorded, and detector settings (equipment and locations) varies among studies (Kunz et al. 2007b). Thus, our best available estimate of mortality levels at a proposed wind project involves evaluation of our on-site bat acoustic data in terms of activity levels, seasonal variation, species composition, and topographic features of the project area.

Activity

Bat activity within the SWRA (mean = 138.4 bat passes per detector-night at combined upland points, 178.0 at the wetland site) was very high compared to that observed at facilities in Minnesota and Wyoming, where bat mortality was low, and it was higher than activity recorded at sites in West Virginia and Tennessee, where bat mortality rates were high (Tables 4 and 5). Thus, based solely on the presumed relationship between pre-construction bat activity and post-construction fatalities, bat mortality rates at SWRA may be higher than many other wind resource areas in the U.S.

Spatial Variation

The proposed wind-energy facility is not located near any large, known bat colonies or other features that are likely to attract large numbers of bats. The nearest known bat hibernaculum is near Trout Lake, located nearly 20 miles north of the SWRA (B. Weiler, WDFW, pers. commun.). The SWRA also does not contain unique topographic features that may funnel migrating bats. The highest bat mortality rates documented at wind energy facilities have been on forested ridgetops in the eastern US. However, the relatively large numbers of bat fatalities recently reported in northern Iowa (Jain 2005) and southwestern Alberta (Baerwald 2006) indicate that an open landscape is also no guarantee of low mortality.

Activity was relatively high at stations SD2 and SD3 compared to other stations, accounting for the majority of the calls recorded during this study. Station SD2 was located adjacent to a wetland, which likely attracts bats for drinking and foraging opportunities. Station SD3 was located in a road clearing through coniferous forest. The linear clearing is likely used as a travel
corridor by local bats in the project area. Bat activity was much lower at the two stations placed within clear cuts.

**Temporal Variation**
The number of bat calls detected per night at the SWRA was highest during July and early August, with activity peaks between July 10 and July 16. Activity in July and early August likely reflects use of the SWRA by local bats during the reproductive season, when pups are being weaned and foraging rates are high. Activity beyond mid-August likely represents movement of migrating bats through the area. Activity by hoary bats was also substantially higher in July, and dropped off significantly beginning in early August. After August 31, activity for all bats was very low relative to earlier dates, indicating that most bats had left the area for winter hibernacula or warmer climates. This suggests higher use of the project area by resident populations of hoary bats as well as other bats, rather than bats migrating through the area. Based on these data, it does not appear that migratory bats are concentrating in the project area.

Fatality studies of bats at wind projects in the US have shown a peak in mortality in August and September and generally lower mortality earlier in the summer (Johnson 2005; Arnett et al. 2008). While the survey effort varies among the different studies, the studies that combine Anabat surveys and fatality surveys show a general association between the timing of increased bat call rates and timing of mortality, with both call rates and mortality peaking during the fall (Kunz et al. 2007b). The highest use of the SWRA occurred in July and early August, prior to the time that most bat mortality occurs at wind resource areas in the Pacific Northwest as well as throughout the US.

**Species Composition**
Of the fourteen species of bat likely to occur in the study area, three are known fatalities at wind-energy facilities (Table 1). Acoustic bat surveys were unable to determine bat species present in the study area (except for hoary bats), but they were able to distinguish high frequency from low-frequency species. Roughly 65% percent of passes at the combined upland stations were by low-frequency bats, suggesting higher relative abundance of species such as hoary bat, silver-haired bat, or big brown bat, while nearly 70% of bat passes at the wetland station were by high-frequency bats, suggesting a higher relative abundance of species such as *Myotis* spp.

**CONCLUSIONS**

Although the data collected during this study indicate relatively high use of the project area by bats, bat activity at the SWRA is not uniquely high among wind resource areas. During a recent Anabat echolocation study conducted at the proposed Grayland Wind Resource Area in Pacific County, Washington during the period August 26 – September 12, 2008, a mean of 219.8 bat passes were recorded per detector night (McGraw et al. 2008). At a proposed wind energy facility at Maple Ridge, New York, Reynolds (2004) recorded an average of approximately 165 bat passes per detector night from late June through early July. The Grayland wind energy project has not been constructed, so post-construction fatality estimates are not available. Bat mortality at the Maple Ridge, New York project was estimated at 11.23/MW/year (Jain et al. 2008), much lower than the pre-construction bat activity levels would suggest. The highest bat
mortality recorded at a wind energy facility in North America was at Mountaineer, West Virginia, where it averaged 38 bats/turbine/year. Pre-construction bat activity levels at Mountaineer as determined by Anabat sampling averaged 38.3 bat passes per detector night. These data suggest that high bat activity levels as determined by Anabat sampling may not necessarily equate to high bat mortality levels.

There are several other factors to suggest that even though bat activity is relatively high at the SWRA, this does not necessarily equate to high risk of bat mortality at the site. No turbines will be constructed near wetlands or ponds, and the cleared corridors along turbine strings will not resemble the narrow road path through the timber that also had high bat activity levels. Bat activity levels recorded at clear cuts in the project area were the lowest, averaging 14.3 and 73.8 bat passes/detector-night at these two locations. These areas most closely resemble what the habitat adjacent to turbines will resemble, because vegetation removal would occur in forested areas where the proposed roadway and turbine alignment is planned. The cleared area would extend 50 feet in all directions from each turbine. From a distance of 50 feet to 150 feet from the base of the turbines, tree heights will be limited to 15 feet above the elevation of the base of the turbine. Areas where trees are permanently removed would be replanted with native grasses and low-growing shrubs, and would therefore resemble habitat at existing clear cuts in the project area.

A substantial proportion of the bat calls recorded at the SWRA were made by high frequency species, including 33% of passes at the upland stations and 69.7% of passes at the wetland station. Although some of these calls may have been made by western red bat (Lasiurus babsoni), most of these calls were likely made by Myotis species. Myotis species are rarely killed at wind energy facilities. At numerous wind resource areas throughout the US, these species have comprised from 0-13.5% of the fatalities, except at one site each in Iowa and Canada, where little brown bats (Myotis lucifugus) made up nearly 25% of the fatalities (Arnett et al. 2008). Myotis species are rarely found at other projects in the Pacific Northwest. Of 337 bat fatalities collected at existing wind-energy facilities in eastern Oregon and Washington, 320 (95.8%) were low frequency species, including 152 hoary bats, 163 silver-haired bats, and five big brown bats. Only one species that emits high frequency calls, the little brown bat, has been found as a turbine fatality in the Pacific Northwest, and the eight little brown bats found comprised only 2.4% of the fatalities (Johnson and Erickson 2008). These data indicate that Myotis bats are much less susceptible to turbine collisions than species that emit low frequency calls, which are primarily the foliage roosting long-distance migrants (i.e., hoary bat and silver-haired bat).

Another important factor to take into consideration is the timing of bat activity recorded at the SWRA. Bat activity from early July through mid-August 2008 was over four times higher than activity from mid-August through early October. Bat activity was also monitored at three sampling locations in the SWRA during the period August 20 – October 21, 2007 (Solick et al. 2008). Anabat units recorded 348 bat passes on 45 detector-nights, resulting in a mean of 7.91 bat passes per detector-night. Both of these stations were located in upland habitats characteristic of proposed turbine locations. These data support the conclusion that bat activity in the SWRA is low from mid August through October. Therefore, much lower activity levels were documented during the time frame that most bat mortality occurs at wind energy facilities.
in the Pacific Northwest, where the peak mortality levels occur from mid-August through September. This time period corresponds with fall migration of the tree bats and dispersal from summer breeding areas to hibernacula for the other species. Bat mortality at wind energy projects throughout the US during the breeding season has been low, as only 4.1% of the fatalities have occurred between May 15 and July 15 (Johnson 2005). At several wind farms studied, low mortality has been documented during the breeding season even though relatively large bat populations were present in the area (Fiedler 2004, Gruver 2002, Howe et al. 2002, Johnson et al. 2004, Schmidt et al. 2003). These data suggest that high bat activity levels during the breeding season do not equate to high bat fatality rates.

Although high bat activity levels were recorded at the SWRA, the available evidence indicates that these data do not necessarily imply that bat fatality levels will be high. Numerous factors, including the timing of the activity, differences in call rates among the various habitats, and species composition of the bat calls suggest that bat mortality may be lower than indicated by the high bat activity recorded. No data on bat mortality levels associated with wind energy developments in western coniferous forests are available to help predict risk to bats at the SWRA. Bat fatality patterns may differ from those in open habitats as well as in eastern deciduous forests.

EXECUTIVE SUMMARY

Western EcoSystems Technology, Inc. initiated surveys in June 2009 designed to assess bat use within the proposed Whistling Ridge Wind Resource Area, Skamania County, Washington. Acoustic surveys for bats using Anabat™ SD1 ultrasonic detectors at three fixed paired (ground and elevated) stations were conducted from June 4 to October 25, 2009. The objective of the acoustic bat surveys was to estimate the seasonal and spatial use of the Whistling Ridge Wind Resource Area by bats. Anabat units recorded 6,805 bat passes during 770 detector nights. Averaging bat passes per detector-night across locations, a mean of 8.09 bat passes per detector-night was recorded.

The majority (71.6%) of the calls were less than 35 kilohertz in frequency (e.g., big brown bat, silver-haired bat, hoary bat), and the remaining calls were greater than 35 kilohertz (e.g., Myotis bat species). Species identification was only possible for the hoary bat, which made up 5.9% of all passes. Activity levels for bat passes peaked in early July, and again in mid-August. Activity levels for hoary bats were highest in mid-August, suggesting this species migrates through the Whistling Ridge Wind Resource Area at this time of year.

The mean number of bat passes per detector per night was compared to existing data from six wind-energy facilities where both bat activity and mortality levels have been measured. The level of bat activity documented at the Whistling Ridge Wind Resource Area was higher than that at wind-energy facilities in Minnesota and Wyoming, where reported bat mortalities are low, but was much lower than at facilities in the eastern US, where reported bat mortality is highest. Assuming that a relationship between bat activity and bat mortality exists, and that it extends to the northwestern US, relatively low levels of bat mortality would be expected to occur in the Whistling Ridge Wind Resource Area; most likely during early July to mid-August.

Based on fatality rates at wind-energy facilities in the western US, the bat call rates observed at this project and habitat of the project area, we expect that the potential risk to bats from turbine operations to be somewhat higher than the rates observed at other western facilities placed in non-forested environments, but not nearly as high as the rates observed at eastern ridgeline facilities. The post-construction monitoring program should be designed to accurately estimate the level of bat mortality.

INTRODUCTION

SDS Lumber Company is proposing to develop a wind-energy facility in Skamania County, Washington. SDS Lumber requested that Western EcoSystems Technology, Inc. (WEST) develop and implement a standardized protocol for baseline studies of bat use in the Whistling Ridge Wind Resource Area (WRWRA) for the purpose of estimating the impacts of the wind-energy facility on bats, and to assist with siting turbines to minimize impacts to bats. The protocol for the baseline study is similar to protocols used at other wind-energy facilities in the United States. The protocol has been developed based on WEST’s experience studying wildlife and wind turbines at projects throughout the US and included passive acoustic sampling using Anabat™ bat detectors to quantify bat use in the WRWRA.

The following is a final report describing the results of Anabat surveys during the 2009 study season within the proposed WRWRA. This represents the third consecutive year that bat acoustical studies have been conducted at the WRWRA. We are not aware of any other proposed wind energy facilities with this extensive level of pre-construction bat activity monitoring. In addition to site-specific data, this report presents existing information and results of bat monitoring studies conducted at other wind-energy facilities. Where possible, comparisons with regional and local studies were made.

STUDY AREA

The proposed WRWRA is in southeast Skamania County approximately four miles (6.44 kilometers [km]) northwest of White Salmon, Washington (Figure 1). The specific project area is just north of Underwood Mountain and includes Sections 5, 6, 7, & 8, Township 3N, Range 10E. The project is located in a forested environment managed for commercial timber production. Topography of the WRWRA consists of hilltops dominated by coniferous forests with some clear cuts and linear clearings associated with power line rights-of-way. Elevation ranges from approximately 1700 – 2400 feet (ft; 518 – 732 meters [m]).

METHODS

Bat Acoustic Surveys

The objective of the bat use surveys was to estimate the seasonal and spatial use of the WRWRA by bats. Bats were surveyed using Anabat™ SD1 bat detectors (Titley Scientific™, Australia). Bat detectors are a recommended method to index and compare use by bats. The use of bat detectors for calculating an index to bat impacts is a primary bat risk assessment tool for baseline wind development surveys (Arnett 2007, Kunz et al. 2007a). Bat activity was surveyed using six detectors from June 4 to October 25, 2009, a period corresponding to summer breeding and fall bat migration at this site. Detectors were placed near the ground at three fixed stations (Figure 1). At each of these stations, ground detectors (WR1, WR3, and WR5) were paired with detectors raised (WR2, WR4, and WR6) on meteorological (met) towers to compare bat activity at different heights (ground versus raised) and monitor bat activity in the rotor-swept zone. Pair
WR1 and WR2 were placed next to an area where timber was being harvested, WR3 and WR4 were placed in an area of regeneration, and WR5 and WR6 were in a clear cut on a ridge with open water at the base of the ridge.

Anabat detectors record bat echolocation calls with a broadband microphone. The echolocation sounds are then translated into frequencies audible to humans by dividing the frequencies by a predetermined ratio. A division ratio of 16 was used for the study (Messina 2004). Bat echolocation detectors also detect other ultrasonic sounds made by insects, raindrops hitting vegetation, and other sources. A sensitivity level of six was used to reduce interference from these other sources of ultrasonic noise. Calls were recorded to a compact flash memory card with large storage capacity. The detection range of Anabat detectors depends on a number of factors (e.g., echolocation call characteristics, microphone sensitivity, habitat, the orientation of the bat, atmospheric conditions; Limpens and McCracken 2004), but is generally less than 30 m (98 ft) due to atmospheric absorption on echolocation pulses (Fenton 1991). To ensure similar detection ranges among detectors, microphone sensitivities were calibrated using a BatChirp (Tony Messina, Las Vegas, Nevada) ultrasonic emitter as described in Larson and Hayes (2000). All units were programmed to turn on each night approximately one half-hour before sunset and to turn off approximately one half-hour after sunrise.

Anabat detectors were placed inside plastic weather-tight containers with a hole cut in the side of the container through which the microphone extended. Microphones were encased in PVC tubing with drain holes that curved skyward at 45 degrees outside the container to minimize the potential for water damage due to rain. Ground units were raised approximately 3.3 ft (one m) off the ground to minimize echo interference and lift the unit above vegetation. Raised Anabat microphones were elevated 147.6 ft (45 m) on meteorological towers using a pulley system. Microphones were encased in a Bat-Hat weatherproof housing (EME Systems, Berkeley, California), and attached to a coaxial cable that transmitted ultrasonic sounds to an Anabat unit at the base of the tower. The Bat-Hat weatherproof housing was modified by replacing the Plexiglas reflector plate with a 45-degree angle PVC elbow, for better comparability with data collected by detectors on the ground.

**Statistical Analysis**

The units of activity were number of bat passes (Hayes 1997). A pass was defined as a continuous series of two or more call notes produced by an individual bat with no pauses between call notes of more than one second (White and Gehrt 2001, Gannon et al. 2003). In this report, the terms bat pass and bat call are used interchangeably. The number of bat passes was determined by downloading the data files to a computer and tallying the number of echolocation passes recorded. Total number of passes was corrected for effort by dividing by the number of detector nights.

For each station, bat calls were sorted into two groups, based on their minimum frequency, that correspond roughly to species groups of interest. For example, species such as western red bat (*Lasiurus blossevillii*) and those in the genus *Myotis* generally echolocate at frequencies above 40 kilohertz (kHz), whereas species such as big brown bat (*Eptesicus fuscus*), silver-haired bat (*Lasionycteris noctivagans*) and hoary bat (*Lasiurus cinereus*) have echolocation frequencies that
fall below 35 kHz. Therefore, we classified calls as high-frequency (HF; > 35 kHz) and low-frequency (LF; <35 kHz) calls. To establish which species may have produced calls in each category, a list of species expected to occur in the study area was compiled from range maps (Table 1; Harvey et al. 1999, BCI website). Data determined to be noise (produced by a source other than a bat) or call notes that did not meet the pre-specified criteria to be termed a pass were removed from the analysis.

Within these categories, an attempt was made to identify calls made by hoary bats. Calls that had a distinct U-shape and that exhibited variability in the minimum frequency across the call sequence were identified as belonging to the *Lasiurus* genus (C. Corben, pers comm.). Hoary bats were distinguished based on minimum frequency; hoary bats typically produce calls with minimum frequencies between 18 and 24 kHz (J. Szewczak, pers comm.). Only sequences containing three or more calls were used for species identification. Given the high intraspecific variability of *Lasiurus* calls, and the number of call files that were too fragmented for proper identification, it is likely that more hoary bat calls were recorded than were positively identified.

The total number of bat passes per detector night was used as an index of bat use in the WRWRA. Bat pass data represented levels of bat activity rather than the numbers of individuals present because individuals could not be differentiated by their calls. To assess potential for bat mortality, the mean number of bat passes per detector night (averaged across ground-based monitoring stations) was compared to existing data from wind-energy facilities where both bat activity and mortality levels have been measured.

**RESULTS**

**Bat Acoustic Surveys**

Bat activity was monitored at three fixed, paired sampling locations over a total of 144 nights during the period June 4 to October 25, 2009. Anabat units operated correctly for the entire night for 89.1% of the sampling period (Figure 2). Levels of wind and insect noise were relatively low throughout the study period (Figure 3). Anabat units recorded 6,805 bat passes on 770 detector-nights (Table 2). Averaging bat passes per detector-night across the locations, a mean of 8.09 ± 0.55 bat passes per detector-night was recorded. The average pass rate was 11.58 ± 0.70 bat passes per detector-night for ground stations and 4.59 ± 0.43 bat passes per detector-night for stations raised on met towers to a height of 45 m.

**Spatial Variation**

Bat activity varied among the Anabat unit pairs in the WRWRA (mean of 8.09 bat passes per detector-night; Figures 1 and 4; Table 2). Most (59.0%) bat calls were recorded at stations WR1 and WR2 (mean of 17.28 and 10.59 bat passes per detector-night, respectively), which were located at the southern-most met tower. Detections were lowest at paired stations WR5 and WR6 (mean of 6.43 and 1.64, respectively), located at the eastern-most met tower. Detections at stations WR3 and WR4, located at the northern-most met tower, were moderate (mean 11.40 and 1.59, respectively; Figure 1 and 4; Table 2).
Comparing paired stations on just the nights that both ground and raised detectors were operating, bat activity was consistently higher at ground stations (Figure 5). The difference in bat activity levels between ground and raised units was much less between WR5 and WR6 than at other detector pairs.

**Temporal Variation**

Bat activity increased from early June through early July, and then peaked during early- to mid-July and again in mid-August (Table 3, Figure 6). Activity decreased through September and October, with small spikes in activity occurred in some weeks. Bat passes were recorded during every week of the survey period, but over half (54.1%) of all bat passes were recorded between July 2 and August 19 (Table 3).

Bat activity levels over time were similar at ground and raised stations (Figure 7). Raised and ground stations recorded similar levels of activity through late June, but ground stations recorded much more activity through the remainder of the study period.

**Species Composition**

Overall, passes by low-frequency bats (LF; 71.6% of all bat passes) outnumbered passes by high-frequency bats (HF; 28.4%; Table 2). Ground units had a similar pattern, with 62.0% of all passes being LF (Table 2; Figures 4 and 5). Among raised stations, LF bats comprised about 98% of all bat passes (Table 2; Figures 4 and 5). Patterns of activity varied slightly between species groups, with the majority (70.0%) of passes by LF species occurring between June 25 and August 26, whereas most (70.7%) passes by HF species occurred between July 23 and September 23 (Table 3; Figures 6 and 7).

Hoary bats comprised 5.9% of total passes detected within the WRWRA, and 8.2% of all low frequency passes (Table 2). Eighty-seven percent of hoary bat passes were detected at raised stations (Table 2; Figure 8). Station WR2 recorded most of the hoary bat activity (77.9% of 399 hoary bat passes). Most of the hoary bat activity was recorded between August 6 and August 26 (Figure 9).

**DISCUSSION**

**Potential Impacts**

Assessing the potential impacts of wind-energy development to bats at the WRWRA is complicated by the current lack of understanding of why bats die at wind turbines (Kunz et al. 2007b, Baerwald et al. 2008), combined with the inherent difficulties of monitoring elusive, night-flying animals (O'Shea et al. 2003). In addition, while installed capacity for wind energy has increased rapidly in recent years, the availability of well-designed studies from existing projects lags development of proposed projects (Kunz et al. 2007b). To date, monitoring studies of wind projects suggest that:

a) bat mortality shows a rough correlation with bat activity as measured by Anabat units (Table 4);
b) the majority of fatalities occur during the post-breeding or fall migration season (roughly August and September);

c) migratory tree-roosting species (eastern red, hoary, and silver-haired bats) comprise almost 75% of reported bat fatalities, and;

d) the highest reported numbers of fatalities occur at wind-energy facilities located along forested ridge tops in the eastern and northeastern US; however, recent studies in agricultural regions of Iowa and Alberta, Canada, report relatively high fatalities as well (Table 4).

Based on these patterns, current guidance to estimate potential mortality levels at a proposed wind project involves evaluation of the on-site bat acoustic data in terms of activity levels, seasonal variation, and species composition (Kunz et al. 2007b), as well as comparison to regional patterns.

**Overall Activity**

To date, six studies of wind energy projects have concurrently recorded both Anabat detections per night and bat mortality (Table 4). Because these concurrent studies show correlation between bat activity and fatality rates, it is assumed that a similar relationship holds for pre-construction activity and post-construction fatalities. The addition of data sets like this one will contribute to our understanding of the relationship between bat activity near wind turbines and bat fatalities. To our knowledge, data for those studies in Table 4 were collected using Anabat detectors placed near the ground (i.e., none raised on metrological towers) and none of the detectors were located near features attractive to bats. Thus, this report relies on the mean activity rate for ground-based detectors placed near metrological towers and/or potential turbine locations to assess potential risk of bat fatality at the WRWRA relative to the six studies with similar data.

Bat activity recorded by ground detectors within the WRWRA (11.58 bat passes per detector-night) was somewhat higher than that observed at facilities in Minnesota and Wyoming, where bat mortality was relatively low, but was much lower than activity levels recorded at sites in West Virginia, Iowa, and Tennessee, where bat mortality rates were higher (Table 3). Thus, based solely on the expected relationship between pre-construction bat activity and post-construction fatalities, bat mortality rates at the WRWRA would be expected to be greater than the 2.4 bat fatalities/MW/year reported at Buffalo Ridge Minnesota, but much lower than the 31.5 fatalities/MW/year reported at Buffalo Mountain, Tennessee.

**Spatial Variation**

The proposed WRWRA is not located near any large, known bat colonies. However, the proposed project is located on forested ridges. In the eastern US, the highest bat fatality rates have been recorded at wind-energy facilities located on forested ridges (Table 4). However, the relatively large numbers of bat fatalities recently reported in northern Iowa (Jain 2005) and southwestern Alberta (Baerwald 2006) indicate that an open landscape does not guarantee low mortality.
Activity at the southern-most met tower (stations WR1 and WR2) was relatively higher compared to other stations, accounting for the majority (59.0%) of the calls recorded during this study. These stations were located next to an area currently being cut, which may have offered bats more foraging opportunities, relative to Anabats stationed in an area undergoing regeneration or in a previously clear cut area. Bat activity was lowest at the paired stations (WR5 and WR6) placed in a clear cut.

**Temporal Variation**

The number of bat calls detected per night at the WRWRA was highest from early June through mid-August. Activity in July likely corresponds with the reproductive season, when pups are being weaned and foraging rates are high. August activity may represent movement of migrating bats through the area. By October, activity dropped to lower rates though a small spike in late October suggests a late migratory wave during that time period.

Fatality studies of bats at wind-energy facilities in the US have shown a peak in mortality in August and September, with generally lower mortality levels earlier in the summer (Johnson 2005, Arnett et al. 2008). Bat mortality at wind energy projects throughout the US during the breeding season has been low, as only 4.1% of the fatalities have occurred between May 15 and July 15 (Johnson 2005). At several wind farms studied, low mortality has been documented during the breeding season even though relatively large bat populations were present in the area (Fiedler 2004, Gruver 2002, Howe et al. 2002, Johnson et al. 2004, Schmidt et al. 2003). These data suggest that high bat activity levels during the breeding season do not equate to high bat fatality rates.

While the survey effort varies among the different studies, the studies that combine Anabat surveys and fatality surveys show a general association between the timing of increased bat call rates and timing of mortality, with both call rates and mortality peaking during the late summer and early fall.

**Species Composition**

Of the 14 species of bat likely to occur in the study area, four are known fatalities at wind-energy facilities (Table 1). Acoustic bat surveys were able to classify bat calls to frequency groups that roughly correspond to groups of relative risk. Approximately 72% of passes were by low-frequency bats, suggesting higher relative abundance of species such as big brown and silver-haired bats, and hoary bats made up 8.2% of all low-frequency passes. These species are known to occur as fatalities at wind turbine operations in the Pacific Northwest and elsewhere (Table 1). Based on data from 10 wind energy facilities in the Pacific Northwest, hoary bats and silver-haired bats have comprised the majority (93.5%) of fatalities, while big brown bats are relatively uncommon wind turbine fatalities, comprising only 1.5% of the fatalities (Johnson and Erickson 2008).

Passes by LF species were more common than those by HF species every week of the study except for a two-week period in mid-September. The relative increase in HF passes at this time may reflect movement of HF species through the area. The high-frequency group at WRWRA would be comprised of the *Myotis* bats, western red bats (*Lasiurus blossevillii*), and the canyon bat (*Parastrellus hesperus*). Bats in the HF group are not typically found during fatality studies,
although little brown bat (*Myotis lucifugus*) fatalities were as common as red bat fatalities in Iowa, 1.7 times as common as silver-haired bats in Alberta, and comprised 10% of fatalities discovered at the Vansycle facility in Oregon (Arnett et al. 2008).

At raised stations, low-frequency passes greatly outnumbered high-frequency passes, which most likely reflects different migration flight heights or foraging patterns among species. Generally, low-frequency species tend to forage in less cluttered conditions (e.g., at greater heights) than high-frequency species due to their wing morphology and echolocation call structure (Norberg and Rayner 1987). To date, hoary and silver-haired bats have been found as fatalities in higher relative proportions than have big brown bats, and are therefore considered to be at greater risk for collision with wind turbines (e.g., Arnett et al. 2008).

Regional Fatality Studies

Bat mortality studies at wind-energy facilities across North America show a wide range of bat mortality rates, ranging from none to 39.70 bat fatalities/MW/year (Table 4). In general, fatality rates have been highest in the Northeast and lowest in the Northwest, although a high degree of variation in fatality rates is present for most regions. To date, bat fatality estimates in the Northwest region have ranged from 0.39 to 2.46 bat fatalities/MW/year, and averaged 1.18 (Johnson and Erickson 2008). However, all of these projects are located in the more arid eastern portions of the region, and it is not clear if similar results can be expected in the more forested western parts of the region.

CONCLUSIONS

The data collected in 2009 represent the third year of bat acoustical studies conducted at the WRWRA. In 2007, bat activity was monitored at two ground stations and one elevated station on a met tower during the period August 20 – October 21 (Solick et al. 2008). Both of these stations were located in upland habitats characteristic of proposed turbine locations. Bat activity levels were similar to those measured in 2009, as the mean number of bat passes per detector night was 7.91. In 2008, Anabat surveys were conducted at four ground stations from July 3 to October 7 (Johnson et al. 2009). Two stations were placed in clear cuts, one was placed along a logging road through a forest, and the fourth was placed adjacent to a pond in the study area to assess levels of bat activity and composition of primarily breeding bats in the project area. For all four units combined, a mean of 148.34 bat passes per detector-night was recorded. However, 80.7% of all calls were recorded at the detector set on the logging road, which was likely used as a travel corridor by bats and was not representative of cleared areas where turbines would be placed. The detector placed near the pond also recorded relatively high activity levels (178.03 bat passes/detector night). Bat activity at the two stations placed in clear cuts comprised only 19.1% of all bat passes recorded during the study (14.30 and 73.76 bat passes/detector night, respectively).

The data collected in 2009 were collected entirely at met tower locations, which were most representative of proposed turbine locations. In addition, the three units elevated on the met towers to a height of 45 m, within the rotor swept zone, likely provide the best data for assessing
risk to bats in the project area (Baerwald 2008). Based on results of the 2009 study, it does not appear that construction of a wind energy facility at the WRWRA would result in high bat mortality levels. However, no data on bat mortality levels associated with wind energy developments in western coniferous forests are available to help predict risk to bats at the WRWRA. Bat fatality patterns may differ from those in open habitats as well as in eastern deciduous forests. Post-construction monitoring of the Whistling Ridge wind energy facility would provide valuable data on bat collision mortality in this environment that would be useful for assessing risk to bats of future proposed wind energy developments in western coniferous forests.

INTRODUCTION AND BACKGROUND

Over the last decade, wind energy development has been occurring in Oregon and Washington within the Columbia Plateau physiographic region (ecoregion). With this development comes the potential for direct impacts to birds and bats through collision mortality and for indirect effects through habitat fragmentation or displacement of birds and other wildlife. Proposals for wind energy developments are commonly reviewed by natural resource agencies, private conservation groups, permitting authorities and other stakeholders. Frequently, baseline studies are conducted to estimate bird and bat abundance at proposed development sites for use in impact assessments and siting project features, followed by post-construction monitoring studies to measure actual impacts from the wind-energy facility.

With the possible exception of golden eagles (*Aquila chrysaetos*) at the Altamont Pass wind-energy facility, California, where an estimated 40–70 golden eagles are killed each year (Hunt 2002, Smallwood and Thelander 2004), no wind-energy facilities have been documented to cause population declines of any species (Johnson and Stephens 2010). The purpose of this report is to estimate cumulative impacts associated with all existing, permitted, and currently proposed wind-energy facilities within the Columbia Plateau Ecoregion (CPE) of eastern Washington and Oregon. This report updates a previous version (Johnson and Erickson 2008) to account for additional bird and bat fatality estimates from the Leaning Juniper and Klondike III wind energy projects in Oregon, as well as additional raw data on species composition of turbine fatalities from the Goodnoe and White Creek wind energy facilities in Klickitat County, Washington and the Pebble and Hay Canyon wind energy facilities in Oregon. For the purpose of this analysis, we assumed that for cumulative impacts to occur, there must be a potential for a long-term reduction in the size of a population of birds or bats. When assessing the potential for cumulative impacts, it is necessary to first define the population potentially affected by wind energy development. Because birds and other animals do not recognize geopolitical boundaries, we have defined the affected population as those birds and bats of each species that breed, winter, or migrate through the CPE.

ANALYSIS AREA AND WIND ENERGY PROJECTS

As of September 2009, there were 4159 MW of wind energy either built or under construction in Washington and Oregon (AWEA 2009), most of which has been within the Columbia Plateau Level III Ecoregion (Thorson et al. 2003; Figure 1). In the earlier version of this cumulative effects analysis (Johnson and Erickson 2008), we attempted to contact every county within the CPE in an effort to estimate future wind energy development based on existing permit applications, which resulted in an estimate of 6700 MW of wind energy development in the CPE. However, past experience indicates that not all of the projects that are proposed will ultimately be issued permits for the size originally proposed and not all permitted projects are built, or fully built-out. Consequently, this method can result in significantly over-estimating future wind energy development. However, for consistency, for the purpose of this analysis, we assumed that 6700 MW of wind power would be present in the CPE. We also calculated the numbers of
fatalities that reflect Northwest Power and Conservation Council (NPCC) estimates, which recognize constraints on wind development, such as transmission capacity. NPCC projects that 5,577 MW of wind energy development will be installed by the year 2013 (Jeff King, Senior Resource Analyst, presentation to the Northwest Wind Integration Forum Steering Committee, January 7, 2010).

The Columbia Plateau was historically characterized by open, arid shrub-steppe and grassland-steppe habitats. The current predominant land use of the Ecoregion is dryland agriculture, land enrolled in the Conservation Reserve Program (CRP), and rangeland (Figure 2). Precipitation through the region is 6 to 12 inches (about 15-30 centimeters) per year (Thorson et al. 2003). Surrounding ecoregions are more mountainous, receive more precipitation, and are more forested than the Columbia Plateau.

**METHODS**

This report provides a broad, qualitative analysis using existing public information about existing and proposed wind-energy facilities in the region, estimated population sizes of birds in the CPE, results of fatality monitoring studies, and published literature to compile a cumulative impact analysis for bird and bat resources. The general approach to the cumulative effects analysis was to summarize results of fatality monitoring studies at operational wind-energy facilities within the CPE, and use those results to estimate impacts for all constructed and proposed wind-energy facilities within the same ecoregion. Habitat and land use throughout the entire CPE are similar. This cumulative effects analysis relies heavily on data from 12 wind-energy facilities in the CPE where at least one full year of monitoring for fatalities has occurred. Most of the operating facilities have had or will have some sort of bird or casualty monitoring associated with them, and post-construction fatality monitoring data are available from 12 operational wind energy facilities in the CPE (Table 1). For each of the individual study areas from which fatality results are available, the predominant land use was a mosaic of agriculture, mainly dryland wheat farming, and grassland or shrub- steppe rangeland used for livestock grazing. In general, the region where future wind-energy facilities are being planned is similar in vegetation types (Quigley and Arbelbeide 1997), although, for any given facility, the amount of each type varies. It is assumed for the analysis that results from the existing studies would be applicable to new proposed facilities.

With the exception of the Condon, Oregon, wind-energy facility, where no scavenging or searcher efficiency trials were conducted to estimate total mortality, the 11 data sets used in this report were collected using similar methods, where observed fatality rates, calculated from standardized carcass searches, were adjusted for searcher efficiency and carcass removal biases. The analysis operates under the assumption that the bird and bat communities are similar across all wind-energy facilities because of habitat and land use similarities throughout the ecoregion, and thus are applicable to proposed facilities in this same ecoregion. Details about results, methods, and estimates of potential bird and bat impacts from each individual wind-energy facility are available in the referenced facility reports.
To define population sizes of those species most likely to be affected by wind energy development in the CPE, we used data from a recent publication that estimates breeding size of bird species by Bird Conservation Region, and then by that portion of each state within the Bird Conservation Region (see Blancher et al. 2007). Those portions of Washington and Oregon within the Great Basin Bird Conservation Region (see US NABCI Committee (2000) for a description) essentially comprise the same area that we have defined as the CPE. To our knowledge these are the only population estimates available for the entire CPE.

**Raptors**

Raptor use estimates and post-construction raptor fatality estimates are available for 12 facilities in eastern Washington and Oregon. Based on available data, it is likely that raptor mortality throughout the CPE would be on the same order of magnitude as other wind-energy facilities in the western US outside California, where it ranges from none to 0.15/MW/year (Johnson and Stephens 2010). Raptor use (raptors/survey) at wind resource areas (WRAs) in the CPE ranges from 0.26 to 1.64, and averages 0.68 observations per 20-min survey (Table 2). This use is substantially lower than that at Altamont Pass and High Winds, two facilities in California that have had relatively high levels of raptor mortality. Similar levels of raptor mortality in the CPE would not be expected. To predict raptor mortality for all existing and proposed wind-energy facilities in the CPE, we assumed it would be similar to the other existing wind-energy facilities in the CPE. Mean annual raptor mortality (fatalities/MW/year) at the 12 existing wind-energy facilities in eastern Washington and Oregon ranges from 0 to 0.21/MW/year, with a mean of 0.077/MW/year. Because the 1.5–3.0 MW turbines constructed or proposed for most new-generation wind-energy facilities are larger than turbines used at most of the existing wind-energy facilities, it is likely not appropriate to predict raptor mortality in the CPE using per turbine estimates from the other wind-energy facilities, as several of the existing facilities used smaller turbines, ranging from 0.66 – 1.5 MW in size. Therefore, we used per megawatt estimates of raptor mortality for extrapolating the estimated numbers of raptor fatalities in the CPE. To estimate cumulative mortality of individual species, we assumed that species composition of bird and bat fatalities associated with 6700 MW of wind energy would be similar to species composition of fatalities found at the 16 existing facilities in the CPE, including 12 with quantified fatality estimates and four with raw data on species composition and number of fatalities. For example, American kestrels (*Falco sparverius*) composed 31.4% of the raptor fatalities found at existing wind-energy facilities. To estimate the total number of American kestrel fatalities associated with 6700 MW of wind energy development, we assumed that they would also compose 31.4% of the total cumulative number of raptor fatalities per year.

**All Birds**

Compared with raptors, there is little correlation between total numbers of birds (all species) observed during pre-construction surveys (most of which are song birds) and post-construction mortality, presumably because many of the collision fatalities are nocturnal migrants (see Table 1), which are not accounted for during diurnal surveys. In addition, the survey methods for quantifying use are more relevant for large birds than for small birds. Total bird use at 24 wind-energy facilities in the CPE has ranged from 5–23.6 birds/survey and averaged 13.4 birds/survey (Table 2). Total bird use at the 12 wind-energy facilities in eastern Washington and Oregon with
post-construction fatality data ranged from 5.0 birds/survey at Wild Horse to 23.6 birds/survey at Leaning Juniper, and averaged 12.0 birds/survey (Table 1). Because total bird use at proposed wind-energy facilities with pre-construction bird use data is within the range of similar bird use values for existing wind-energy facilities in the CPE, it is reasonable to assume that mortality of all birds combined at CPE wind-energy facilities would be similar to that observed at the 12 existing wind-energy facilities in the CPE. Therefore, we multiplied the total number of MW by 2.5 fatalities/MW/year (the mean among the 12 CPE wind-energy facilities) to estimate total bird mortality. To estimate total cumulative mortality by bird type and/or species, we assumed the fatalities associated with 6700 MW of wind energy would have the same group and species composition as fatalities found at existing wind-energy facilities in the CPE.

**Bats**

To estimate cumulative bat mortality for all projects in the CPE, we assumed that bat mortality would be similar to the existing wind-energy facilities located in the CPE. Therefore, we multiplied the total number of MW by the mean number of bat fatalities/MW/year at the other CPE Projects (1.20/MW/year). We estimated the total number of fatalities by species assuming species composition would be similar to the species composition of bat fatalities found at existing wind-energy facilities in the CPE.

**RESULTS**

**Existing Data for CPE Projects**

**Raptors**

Raptor use estimates and post-construction raptor fatality estimates are available for 12 wind-energy facilities in eastern Washington and Oregon. Pre-construction raptor use estimates at these wind-energy facilities have ranged from 0.26 raptors/survey at Nine Canyon, to 0.90 raptors/survey at Bighorn I, and averaged 0.52/survey (Table 2). Raptor mortality was not documented at four of these wind-energy facilities (Klondike I, Klondike III, Vansycle and Combine Hills) during one-year post-construction mortality surveys, and was relatively low at the other eight, ranging from 0.05/MW/year at Nine Canyon, Washington to 0.21/MW/year at Leaning Juniper, Oregon. Quantitative mortality estimates were not made for Condon, but only one raptor fatality was documented at that facility.

The 70 raptor fatalities found at CPE wind-energy facilities have composed 8.4% of the total bird mortality. Most of the raptor fatalities have been American kestrels (22 fatalities; 31.4%), red-tailed hawks (*Buteo jamaicensis*; 14 fatalities; 20.0%) and short-eared owls (*Asio flammeus*; 7 fatalities; 10.0%). Other raptors found as fatalities at CPE wind-energy facilities include six Swainson’s hawks (*Buteo swainsonii*), four ferruginous hawks (*Buteo regalis*), three rough-legged hawks (*Buteo lagopus*), two of each of the following: great horned owl (*Bubo virginianus*), long-eared owl (*Asio otus*), northern harrier (*Circus cyaneus*), unidentified buteo, and one each of the following: golden eagle (*Aquila chrysaetos*), Cooper’s hawk (*Accipiter cooperii*), sharp-shinned hawk (*Accipiter striatus*), barn owl (*Tyto alba*), unidentified owl, and unidentified accipiter (Table 3).
All Birds
Eighty-nine species have occurred as fatalities at existing wind energy facilities in the CPE. Passerines (songbirds) have been the most abundant bird fatality at modern wind-energy facilities in western North America, comprising 59.3% of total bird fatalities (Johnson and Stephens 2010). Passerines are also the most commonly observed birds during pre-construction fixed-point bird use surveys at all of these sites. Both migrant and resident passerine fatalities have been observed. Songbird mortality at wind-energy facilities in eastern Oregon and Washington has been reasonably consistent among sites. Songbirds have composed 67.1% of the bird mortality at CPE wind-energy facilities. Horned larks (Eremophila alpestris) have been the most commonly observed songbird fatality in the CPE, composing 29.7% of all bird fatalities (Table 3), and have been the most abundant songbird observed during pre-construction fixed point bird use surveys at these sites. Based on long term Breeding Bird Survey (BBS) data, horned larks are likely one of the most common birds in the Columbia Plateau. No other resident songbird species comprised a large proportion of the fatalities observed at the wind-energy facilities in the CPE (Table 3). The one apparent migrant with the highest number of fatalities is the golden-crowned kinglet (Regulus satrapa; 47 fatalities; 5.6% of all fatalities).

Mourning doves (Zenaida macroura) and rock pigeons (Columba livia) have composed 4.3% of the mortality at CPE wind-energy facilities. Waterfowl, waterbirds and shorebirds have composed only 2.1% of the fatalities. Mortality compared to use by these groups is very low. For example, only two Canada goose fatalities were documented at the Klondike, Oregon wind-energy facility (Johnson et al. 2003a), even though 43 flocks totaling 4845 individual Canada geese were observed during pre-construction fixed-point bird use surveys (Johnson et al. 2002a). Shorebird use of wind-energy facilities in the CPE has been low, with the most common species being killdeer. Shorebirds as a group are rarely killed at wind-energy facilities; of 1247 avian fatalities collected at modern wind-energy facilities in western North America and summarized in Johnson and Stephens (2010), only three (0.2%) were shorebirds. Low shorebird mortality has occurred even though shorebirds have been recorded at virtually every wind-energy facility evaluated. Some waterfowl, shorebird and other waterbird mortality will occur at CPE wind-energy facilities, but based on all available data from other facilities, the numbers are expected to be low relative to the use of each area. Upland gamebirds documented during surveys of CPE wind-energy facilities include ring-necked pheasant (Phasianus colchicus), gray partridge (Perdix perdix), chukar (Alectoris chukar), and California quail (Callipepla californica). Upland gamebird mortality is fairly common, as upland gamebirds have comprised 9.6% of all fatalities at modern wind energy facilities in western North America, behind only passerines and raptors (Johnson and Stephens 2010). In the CPE, upland gamebirds are one of the most common fatalities, composing 12.6% of all identified fatalities (Table 4). Based on habitat present, results from other regional wind-energy facilities, and the presence of upland gamebirds during baseline surveys, some mortality of upland gamebirds is expected to occur at nearly all wind-energy facilities in the CPE.

Bats
Bat mortality estimates have been made for 11 existing wind-energy facilities in the CPE, where they ranged from 0.23–2.46 fatalities/MW/year, and averaged 1.20 fatalities/MW/year (Table 5). Bat mortality patterns at wind-energy facilities in Washington and Oregon have followed patterns similar to the rest of the country. Of 390 bat fatalities collected at existing wind-energy facilities.
facilities in eastern Oregon and Washington, 364 (93.4%) have been the two migratory species that occur in the CPE, including 180 hoary bats (*Lasiurus cinereus*) and 184 silver-haired bats (*Lasionycteris noctivagans*). The other mortalities have consisted of small numbers of big brown bats (*Eptesicus fuscus*), little brown bats (*Myotis lucifugus*), and unidentified bats (Table 6). Virtually all of the mortality has occurred in late summer and early fall, during the fall migration period for hoary and silver-haired bats.

**Mortality Estimates and Population Consequences**

**Birds (Excluding Raptors)**
For all birds combined, we estimate that total annual mortality in the CPE would be 16,750 birds/year. Despite several thousand bird fatalities from 6700 MW of wind power, these impacts are spread across numerous species and bird groups, as well as across seasons. Therefore, the overall impact to any given species or population of a species is substantially less. Based on species composition of fatalities at existing CPE wind-energy facilities (Table 3), passerines would compose approximately 67.1% of the fatalities, upland gamebirds would compose 12.6%, doves/pigeons would compose 4.3%, waterfowl/waterbirds/shorebirds would compose 2.1% and other bird types, such as woodpeckers, nighthawks and swifts, would compose 3.0%. Approximately 4.5% of the mortality would be composed of non-protected European starlings (*Sturnus vulgaris*), rock pigeons and house sparrows (*Passer domesticus*)

**Raptors**
Using raptor mortality estimates from existing wind energy facilities in the CPE, we estimate total raptor mortality in the CPE would be 516 fatalities per year. American kestrels account for 31.4%, red-tailed hawks account for 20.0% and short-eared owls account for 10.0% of the raptor fatalities recorded at the regional wind projects studied (see Table 3). Assuming this trend holds true for all proposed wind-energy facilities in the CPE, and assuming there would be 516 raptor fatalities per year, it would be expected that on average 162 American kestrels, 103 red-tailed hawks and 52 short-eared owls would be killed each year.

The other species of raptors occurring in the CPE have had no or few fatalities at existing wind-energy facilities, and would likely represent a much smaller number of fatalities. For example, no peregrine falcon (*Falcon peregrinus*) or prairie falcon (*Falco mexicanus*) fatalities have been reported to date; therefore, our mortality estimate for this species is necessarily zero. Although one prairie falcon was found in the parking lot of the White Creek wind energy facility, it was not considered turbine related and was therefore not included in this analysis. Three species of concern in the region, golden eagle, ferruginous hawk and Swainson’s hawk, have all been found as turbine collision victims in the CPE. Ferruginous hawks have composed 5.7% of the raptor fatalities, Swainson’s hawks have composed 8.6%, and golden eagles have composed 1.4%. Assuming a total of 516 raptor fatalities could occur each year in the CPE, this would result in 29 ferruginous hawk, 44 Swainson’s hawk, and seven golden eagle fatalities per year.

The three species of raptors with the largest expected numbers of fatalities due to wind energy development in the CPE are American kestrel, red-tailed hawk and short-eared owl. Raptor fatalities in the CPE have occurred throughout the year, with 23.1% in the spring, 43.1% in the summer,
21.5% in the fall, and 10.8% in the winter (Table 7). Approximately 56.9% of the raptor fatalities have occurred during the spring and fall migration, and during winter periods, when the affected population could contain birds from numerous local breeding populations in the Pacific Northwest as well as further north in Canada. Assuming approximately 43.1% of the mortality would occur during the breeding season, it would be expected that approximately 70 American kestrel, 44 red-tailed hawk and 22 short-eared owl fatalities would occur during the breeding season. An estimate of the breeding population in the Columbia Plateau, based on the BBS long-term average data, is approximately 170,000 breeding American kestrels, 77,000 breeding red-tailed hawks and 21,000 breeding short-eared owls (Blancher et al. 2007). Annual collision mortality in the CPE would represent approximately 0.04% of the breeding population of American kestrels, 0.06% of the breeding population of red-tailed hawks and 0.10% of the breeding population of short-eared owls. Even if we assumed all mortality (instead of 43.1%) would occur to adult breeding birds, this would still represent only 0.10%, 0.13% and 0.25% of the breeding American kestrels, red-tailed hawks and short-eared owls, respectively, in the CPE. Background mortality for these species is much higher than this estimate and the additional wind energy related mortality is likely insignificant from a population standpoint. Typical annual mortality rates for red-tailed hawks are 54% of juveniles, 20% of subadults, and 20% of adults. American kestrels suffer even higher mortality, as the annual mortality rate is 69% of juveniles and 45% of adults (Millsap and Allen 2006). Annual survival data are not available for short-eared owls (Wiggins et al. 2006). Given these numbers, plus the fact that most raptor populations can withstand additional harvest of nestlings and migrating birds by falconers of 10-20% or even higher (Millsap and Allen 2006), it is unlikely that the additional mortality of <0.30% associated with projected wind power development in the CPE would lead to measurable population effects for American kestrels, red-tailed hawks and short-eared owls. Based on an analysis of population sizes and survival rates, the US Fish & Wildlife Service conservatively estimates that falconers could harvest 13,216 juvenile red-tailed hawks and 19,575 juvenile American kestrels each year in the US without any consequences to populations (Millsap and Allen 2006). Actual harvest by falconers in 2004 was only 1062 raptors comprised of 15 species (Milsap and Allen 2006). Given these estimates of a sustainable harvest and the actual number of birds harvested, the number of birds killed in 2004 by wind turbines in North America should have fallen into a range of sustainable mortality.

Even though only four ferruginous hawk, six Swainson’s hawk, and one golden eagle fatalities have been found at existing wind energy facilities in the CPE, these raptors are species of concern and warrant additional analysis. The ferruginous hawk is listed as threatened by the Washington Department of Fish and Wildlife (WDFW) and as “critical” by the Oregon Department of Fish and Wildlife (ODFW), while the Swainson’s hawk is listed as “vulnerable” by the ODFW. The estimated breeding population in the CPE is 1000 ferruginous hawks (Blancher et al. 2007). Ferruginous hawks may occur in the CPE throughout the year and their populations include breeders, migrants and winter residents, as well as juveniles and adults. Given our estimate of 29 ferruginous hawk fatalities on an annual basis, even if all turbine mortality occurred to resident breeding adult birds, this would represent 2.9% of the breeding ferruginous hawks in the CPE. Because mortality would likely be spread out among migrants, winter residents, resident breeders, and juveniles as well as adults, mortality of adult ferruginous hawks actually breeding in the CPE would be less than 2.9%, likely on the order of 1–2%. According to Millsap and Allen (2006), ferruginous hawk populations can sustain 1% harvest rates (limited to juveniles) without affecting
populations. This harvest rate was considered conservative because it was modeled using data obtained from red-tailed hawk banding or marking studies, which typically greatly underestimate survival in raptors compared to telemetry studies. Therefore, the sustainable harvest rate is likely greater than 1%. To put a 1-2% mortality rate into perspective, we examined existing mortality rates of ferruginous hawks. A study of ferruginous hawks in Washington State found that annual adult mortality was 24%, and mortality of juvenile ferruginous hawks was 57% between the first and second year (Watson 2003). A ferruginous hawk banding study in Alberta, Canada found that first year mortality was 60% (Schmutz and Fyfe 1987), and a study of ferruginous hawks in Utah found that annual mortality was 25% for adults and 66% for juveniles the first year (Woffinden and Murphy 1989). Another study in Canada (Alberta and Saskatchewan) found that annual adult mortality was 29.2%, and first year mortality of nestlings was 45.5%. Despite annual adult mortality of 29.2%, the authors concluded that adult survival was not limiting the population; abundance of ground squirrels, which affected nesting success, appeared to be the primary factor regulating population size (Schmutz et al. 2008). Given published annual mortality rates for adult ferruginous hawks of 24–30%, additional losses of 1–2% of resident breeders associated with 6700 MW of wind energy development in the CPE would not likely have measurable population consequences.

The above analysis is for the entire population of 1000 ferruginous hawks in the CPE. It assumes that wind energy development and ferruginous hawk populations are spread uniformly across the entire CPE, which is not the case. Given the actual locations of existing and proposed wind energy facilities and ferruginous hawk population centers, actual impacts are likely lower. For example, the existing and proposed wind energy development in Klickitat County, Washington is approximately 1902 MW, or 28% of the 6700 MW of all currently existing and proposed wind energy development in the CPE. However, only three breeding pairs of ferruginous hawk are known to occur in the county (Jim Watson, Wildlife Research Scientist, Washington Department of Fish and Wildlife, pers. commun). Therefore, the county with the largest amount of wind energy development has a low breeding population of ferruginous hawks, which reduces the potential for significant impacts to this species across its entire range in the CPE. There is consequently little overlap between areas of intensive wind energy development and core breeding areas for ferruginous hawk, which further reduces the potential for cumulative impacts to this species. Although local populations of ferruginous hawk may be reduced in areas of intensive wind energy development, the evidence suggests that this impact is not likely to affect the ferruginous hawk population in the entire CPE.

Breeding Bird Survey data collected over the last 27 years (1980–2007) show a negative trend in population growth for ferruginous hawks in the CPE (Sauer et al. 2008), but the negative trend is not statistically significantly due to low sample sizes and uncertainty (Sauer et al. 2008). If ferruginous hawk populations are declining in the region, and wind energy development continues at its current rate of growth in the CPE, ferruginous hawk collision mortality could eventually reach a point that populations may begin to decline without some form of mitigation. Mitigation could include establishing conservation easements around ferruginous hawk breeding territories, erecting artificial nest structures, or otherwise improving habitat for ferruginous hawks in the CPE (Johnson et al. 2007).
The estimated Swainson’s hawk breeding population in the CPE is 10,000 (Blancher et al. 2007). Unlike ferruginous hawks, Swainson’s hawks occur in the CPE only during summer and most are resident breeders. Given our mortality estimate of 44 Swainson’s hawks per year, this would represent only 0.44% of the Swainson’s hawks in the CPE. Compared to many other raptor species, there is little data on annual survival of Swainson’s hawks (England et al. 1997). The annual mortality rate of Swainson’s hawks was reported in one study from western Canada, where it was estimated to be 15.7%, and nestling mortality rates ranged from 56–81% over the multi-year study (Schmutz et al. 2006). Given these mortality rates, additional losses of <0.5% would be considered sustainable and would not have measurable population consequences.

The golden eagle is federally protected by the Bald and Golden Eagle Protection Act and is listed as a candidate species by the WDFW, but does not have any special status in Oregon. The estimated breeding population in the CPE is 1770 (Blancher et al. 2007). Golden eagles may occur in the CPE throughout the year and their populations include breeders, migrants and winter residents, as well as juveniles and adults. Given our annual estimate of seven golden eagle fatalities, even if all turbine mortality occurred to resident breeding adult birds, this would represent 0.4% of the breeding golden eagles in the CPE. Because mortality would likely be spread out among migrants, winter residents, resident breeders, and juveniles as well as adults, mortality of adult golden eagles that breed in the CPE would be less than 0.4%. Mortality of golden eagles the first year after independence ranges from 54% to 82% (Kochert et al. 2002). At the Altamont Pass Wind Resource Area in California, mortality of radio-marked golden eagles was 16% the first year, 21% for floating birds one to three years old, and 9% for adult breeders (Hunt 2002). Based on a regression analysis of banding data, Harmata (2002) estimated that only 50% of golden eagles survive to the age of three years. Given these published mortality rates for golden eagles, additional losses of <0.4% of the population associated with 6700 MW of wind energy development in the CPE would not likely have measurable population consequences for golden eagles.

Upland Gamebirds

Upland gamebirds represent a higher percentage (12.6%) of the bird fatalities in the Columbia Plateau than in other regions in the US. No native upland gamebirds have been found as fatalities at wind-energy facilities in the CPE. All of the fatalities have been ring-necked pheasant, gray partridge, and chukar, which are all introduced species. Given our total bird mortality estimate of 16,750, approximately 2110 upland gamebird fatalities would be expected to occur on an annual basis.

The species most impacted, ring-necked pheasant, gray partridge, and chukar, are all common in mixed agricultural native grass/steppe habitats. Habitats throughout the Columbia Plateau are highly suitable for these species and the large populations likely influence the higher mortality rate for the regional wind-energy facilities. The total estimated population size of these three species combined in the CPE of Oregon and Washington is 370,900 (Blancher et al. 2007); therefore, wind energy fatalities would compose approximately 0.57% of the population. As with non-native (non-protected) passerine species, there is generally lower concern over impacts to exotic upland gamebirds. Given the vast amount of suitable habitat and the ability of these species to withstand harvest rates substantially higher than 0.57%, it is unlikely that additional fatalities from wind energy development would be significant from a population standpoint.
Waterfowl, Waterbirds and Shorebirds

Waterfowl, waterbirds and shorebirds represent a very small percentage (2.1%) of all fatalities at existing wind energy projects in the CPE. Based on our total bird mortality estimate of 16,750, approximately 352 fatalities could result on an annual basis.

Populations of waterfowl, waterbirds and shorebirds in the CPE are considerable. In addition, members of these groups are present year-round in the form of resident breeders, migrants, and winter residents. Given that we estimate only a few hundred individuals will be killed by turbine collisions on an annual basis, no cumulative impacts on these species are likely. In addition to killdeer, another shorebird commonly associated with upland habitats where wind-energy facilities are placed, is long-billed curlew. To date, however, only one fatality of this sensitive species has been documented at existing wind-energy facilities in the CPE.

Passerines

For projects in the CPE, approximately 67.1% of the bird fatalities have been passerines (Table 5). Assuming that 67.1% of all bird mortality would be composed of passerines, approximately 11,239 passerine fatalities would occur annually in the CPE. Of all passerine fatalities recorded during the regional monitoring studies, horned lark made up nearly half (44.3%) of the fatalities. Assuming this pattern holds for all CPE wind-energy facilities, it could be expected that on average there would be 4975 horned lark fatalities per year. Another common grassland breeder in the CPE, western meadowlark (Sturnella neglecta), composed approximately 4.8% of the passerine fatalities at wind-energy facilities, and therefore total annual mortality of this species related to wind turbine collisions would be approximately 540 individuals. At wind-energy facilities in the CPE, migrant passerines of several species generally composed approximately 30% of the bird fatalities (Table 1). Assuming these estimates are representative of all CPE wind-energy facilities, approximately 5025 nocturnal migrant fatalities would be expected per year if 6700 MW of wind power were constructed. The most common migrant fatality at existing wind-energy facilities in the CPE was golden-crowned kinglet (Table 3). Approximately 5.6% of the passerine fatalities were of this species; therefore, estimated annual mortality for this species would be approximately 938 individuals.

According to Blancher et al. (2007), the estimated size of the breeding population of horned larks in that portion of the CPE in Washington and Oregon is 2.2 million. Given our estimate of 4975 horned lark fatalities, and if it is assumed that the horned lark fatalities are spread equally over the year, then roughly 25% (~1244) of these fatalities would be during the breeding season. This represents approximately 0.06% of the breeding horned lark population. Given that most of the mortality will be composed of common species with widespread distribution and large populations, that annual mortality rates of song birds typically range from 30–70% (Lack 1966; Welty 1982), losses amounting to less than one percent are impacts to individuals, and therefore not significant from a population standpoint.

While this example represents a plausible means of addressing potential population impacts under a number of assumptions, it illustrates the low level of effect on the common grassland/agricultural species that comprise the largest portion of the fatalities. Similar examples could be used for the other species that illustrate lower effects. For example, the BBS data indicate the breeding
population of western meadowlarks in the CPE of Oregon and Washington is one million (Blancher et al. 2007). Given our estimate of 540 western meadowlark fatalities, the impact on the western meadowlark breeding population in the Columbia Plateau would be minor and insignificant. The number of fatalities from other species are even fewer (see Table 3) and unlikely to have any population effects.

In general, while modern turbines are getting taller, new wind-energy facilities do not appear to have a large impact on migrant birds. Results of marine radar surveys for proposed wind-energy facilities have indicated that the vast majority of nocturnal migrants fly at altitudes that do not put them at risk of collision with turbines (Young and Erickson 2006). Also, there have been only two multiple individual mortality events during a migration season reported at newer wind-energy facilities in the US. At Buffalo Ridge, Minnesota, fourteen migrating passerine fatalities (vireos, warblers, flycatchers) were observed at two turbines during a single night in May 2002 (Johnson et al. 2002b), and 33 migrating passerine fatalities (mostly warblers) were observed near one turbine and a well-lit substation at the Mountaineer, West Virginia, wind-energy facility in May 2004 (Kerns and Kerlinger 2004). At wind-energy facilities in the CPE, migrant passerines of several species generally composed approximately 30% of the bird fatalities. Some impacts are expected for nocturnal migrating species; however, impacts are not expected to be great for the CPE. The apparent migrant with the greatest number of collision fatalities is golden-crowned kinglet. Our annual mortality estimate for golden-crowned kinglet was 938, which would represent 0.13% of the estimated breeding population size of this species in the CPE of Oregon and Washington, which is 720,000 (Blancher et al. 2007). Golden-crowned kinglets are typically associated with forested habitats during the breeding season, so it is assumed that many of the impacted individuals were from surrounding mountainous ecoregions or populations further north (e.g., Canada), rather than from the CPE. As with horned lark, estimating the potential population size from which these birds came requires a number of assumptions. However, while the potential population size is unknown, it is possible that the individual fatalities came from several populations in surrounding or more northern ecoregions, thus further diluting the impacts on any one population. Other potential migrant species were found in lower numbers. Cumulatively the impacts to migrants would be spread over a much larger population base and are not considered significant.

Sensitive Bird Species
In addition to golden eagle and ferruginous and Swainson’s hawks discussed above, other species classified as sensitive species by the WDFW and/or ODFW have been found as fatalities at CPE wind energy projects. These include long-billed curlew (Numenius americanus), Lewis’s woodpecker (Melanerpes lewis), grasshopper sparrow (Ammodramus savannarum), sage thrasher (Oreoscoptes montanus), sage sparrow (Amphispiza belli) and Vaux’s swift (Chaetura vauxi). Only one fatality of each of the above species has been found at CPE wind energy projects. Given that 837 bird fatalities have been found at these projects and estimated total bird mortality is 16,750, the estimated mortality for each of these species would be approximately 20 fatalities per year. The estimated population sizes of each of these species in the CPE based on Blancher et al. (2007) is 25,000 Lewis’s woodpeckers, 149,000 grasshopper sparrows, 1,060,000 sage thrashers, 314,000 sage sparrows, and 110,000 Vaux’s swifts; no estimate was provided for long-billed curlew. Given these estimated populations sizes, the loss of 20 individuals per year would not have measurable population consequences.
Bats

Based on bat mortality estimates at the other regional wind-energy facilities, total bat mortality in the CPE was estimated at 8040 per year. Based on species composition of bat fatalities found at CPE wind-energy facilities, approximately 3795 silver-haired and 3714 hoary bat fatalities would occur in the CPE on an annual basis.

Unlike birds, there is little information available about population sizes of most bat species, especially the non-hibernating, solitary tree-roosting species that compose most of the wind-energy facility related mortality in North America. Results of monitoring studies across the US and Canada have found similar trends in impacts. Risk to bats from wind turbines is unequal across species and across seasons. The majority of bat fatalities at wind projects in western North America have been tree roosting bats that are long-distance migrants (Johnson and Stephens 2010). Silver-haired bats throughout the US and species in the *Lasiurus* genus, the hoary bat in the western U.S. and the eastern red bat (*L. borealis*) in the Midwest and eastern U.S., are the most abundant fatalities found at wind-energy facilities. Less common fatalities include big brown bats and *Myotis* species (Arnett et al. 2008, Johnson 2005, Johnson and Stephens 2010). The highest mortality occurs during the fall migration period for bats, from roughly late-July through September (Arnett et al. 2008, Johnson 2005). Much lower mortality rates occur in the spring and summer, particularly in the CPE.

More recently, studies at different locations in the US and Canada appear to indicate that bat mortality is not related to site features or habitat, and dissimilar results for ecologically similar facilities have been found (Baerwald and Barclay 2009). While it is hypothesized that eastern deciduous forests in mountainous areas may be the highest risk areas, relatively high bat mortality has also occurred at wind-energy facilities in prairie/agricultural settings (Alberta, Canada; Baerwald 2008) and row crop agricultural settings in the Midwestern US (Jain 2005, Gruver et al. 2010). Bat mortality in the CPE would involve primarily silver-haired and hoary bats. Most mortality is observed during the fall migration period. The regional monitoring studies suggest resident bats do not appear to be significantly affected because very low numbers of resident bat species have been observed as fatalities. One species of potential concern is the Townsend’s big-eared bat (*Corynorhinus townsendii*), a state candidate species in Washington. Very little is known about the current distribution of Townsend’s big-eared bat in Washington. According to Marshall et al. (1996) the subspecies *Corynorhinus townsendii pallescens* occurs east of the Cascade Range, within the CPE. A Biological Assessment prepared to address the potential for a wind-energy facility in West Virginia to impact the federally endangered Virginia big-eared bat (*Corynorhinus townsendii virginianus*), a subspecies of Townsend’s big-eared bat, concluded that the collision risk to this species is very low because it is non-migratory and forages well below the space occupied by turbine blades (Johnson and Strickland 2003). These conclusions are also likely applicable to Townsend’s big-eared bat, and to date no fatalities of this species have been found at any wind energy facility in the CPE.

Hoary bats and silver-haired bats occupy forested habitats during the breeding season – habitat distinctly lacking and localized throughout the CPE. The significance of wind energy impacts on hoary and silver-haired bat populations is difficult to predict, as there is no information available on the overall population sizes of these bats. However, hoary and silver-haired bats are widely
distributed throughout North America. Most concern over impacts to bats is with wind-energy facilities built on ridgetops in the Appalachian Mountains, where mortality levels have been as high as 39.7 bat fatalities/MW/year (Kerns et al. 2005), substantially higher than the average of 1.20 bat fatalities/MW/year observed in the Pacific Northwest.

In general, mortality levels on the order of one to two bats per MW are likely not significant to populations, although cumulative effects may have greater consequences for long-lived, low-fecundity species such as bats. Unlike many bird species that may have multiple clutches of multiple young per year, bats are long-lived species with relatively low reproductive rates. For example, hoary and silver-haired bats typically produce only two young per year (Shump and Shump 1982, Kunz 1982). As such, their populations are much slower to recover from large fatality events than other species, such as most birds, that have much higher reproductive rates. Bats tend to live longer than birds, however, and may have a longer breeding lifespan. The impact of the loss of breeding individuals to populations such as these may have greater consequences.

Because migratory tree bats are primarily solitary tree dwellers that do not hibernate, it has not been possible to develop any suitable field methods to estimate their population sizes (Carter et al. 2003). As a result, impacts on these bat species caused by wind energy development cannot be put into perspective from a population impact standpoint. To help solve this problem, population genetic analyses of DNA sequence and microsatellite data are being conducted to provide effective population size estimates, to determine if populations are growing or declining, and to see if these populations are comprised of one large population or several discrete subpopulations that use spatially segregated migration routes (Amy L. Russell, Assistant Professor, Grand Valley State University, Allendale, Michigan, pers. commun.).

Since it is most likely breeding populations from surrounding mountainous/forested ecoregions or from more northern areas (e.g., Canada) are affected at the Columbia Plateau wind-energy facilities during the fall migration, the dynamics of these populations would need to be known to predict population effects. For large and stable populations the level of impact is not expected to be significant, although impacts could be more pronounced for less stable populations. Bat Conservation International (BCI), the American Wind Energy Association (AWEA), the US Fish & Wildlife Service (USFWS), and the US Department of Energy National Renewable Energy Laboratory (NREL) have initiated a research effort termed the Bat Wind Energy Cooperative to conduct research and further understand bat and wind turbine interactions and how to prevent or minimize bat fatalities at wind energy facilities.

**Indirect Effects**

Grassland and shrub-steppe communities are the most abundant native communities in the CPE, but they are also highly subjected to development and conversion to agriculture (Johnson and O’Neil 2001). In addition to potentially thousands of new vertical structures, added wind energy generation in the region will result in more roads (mostly dirt and gravel) and increased human activity due to turbine construction and maintenance. A substantial portion of these impacts will be to already heavily-disturbed agricultural fields and moderately disturbed rangeland used for...
livestock grazing. The percent of direct impacts actually occurring in native grassland or shrub-steppe habitat are difficult to predict and would be based on individual facility design and layout. However, based on the community types that existing wind-energy facilities are located in, we assume that approximately 25% of the existing and proposed facilities would be in cultivated cropland. Based on terrestrial vegetative communities in the CPE (Figure 2), only seven of the 47 existing or proposed wind energy facilities as of late 2008 were in communities classified as shrub steppe, with two additional facilities in areas classified as grasslands. The remaining facilities were all within vegetative communities classified by Quigley and Arbelbeide (1997) as agricultural lands. These lands include croplands as well as rangelands used for cattle grazing, but are apparently degraded such that they are no longer classified as shrublands or grasslands. Therefore, most of the wind energy facilities in the CPE are in areas already degraded to some extent from conversion to pastures and cultivated cropland.

Assuming that on average the permanent impacts associated with a turbine and the associated access roads are 1.5 acres per turbine, and that 1.5-3.0 MW turbines are used for all new projects in the foreseeable future, then approximately 5000 acres (7.8 mi²) of non-agricultural vegetation types, primarily grassland shrub-steppe vegetation, would be lost in the CPE with 6700 MW of wind energy. These impacts would be spread over a large area geographically (see Figure 1). Given that the CPE is 32,096 mi² in size, permanent impacts associated with 6700 MW of wind energy development would represent only 0.02% of the area.

While the CPE covers a large area, and characteristic grassland shrub-steppe habitat is widespread, it is also heavily fragmented by agricultural activities. Species that depend on native habitat face physical and ecological barriers within the region and at the region’s edges. The Columbia River, and other smaller rivers in the area, cut deep canyons and present linear alteration to the general physiography and potential barriers to some animal species movement. Large swaths of agricultural land are less obvious, but may pose significant obstacles to small or less mobile animals. While many birds are not impeded by such physical barriers, some smaller, habitat-specific birds that depend on brushy habitats for cover could be affected by such habitat fragmentation. Habitat specialists and obligates such as greater sage-grouse (*Centrocercus urophasianus*) and sage sparrow (*Amphispiza belli*) require large tracts of continuous sage habitat (Johnson and O’Neil 2001), which is largely missing from the Columbia Plateau, and the range for these species in the Columbia Plateau is already severely restricted. Assuming that agricultural vegetation types are not important wildlife habitat, habitat loss impacts are not expected to be a significant loss to any given species within the entire CPE. However, because existing and proposed wind-energy facilities tend to be concentrated within certain regions within the CPE (see Figure 1), habitat loss may lead to localized population declines of some species.

In addition to direct effects through collision mortality, wind-energy development results in direct loss of habitat where infrastructure is placed and indirect loss of habitat through behavioral avoidance and habitat fragmentation. Direct loss of habitat associated with wind-energy development is relatively minor compared to most other forms of energy development. Although wind-energy facilities can cover substantial areas, the permanent footprint of facilities such as the turbines, access roads, maintenance buildings, substations and overhead transmission
lines, generally occupies only 5 to 10% of the entire development area (Bureau of Land Management [BLM] 2005). Estimates of temporary construction impacts range from 0.2 to 1.0 ha (0.5 to 2.5 ac) per turbine (AWEA 2009). Behavioral avoidance, however, may reduce habitat suitability over much larger areas for some species of wildlife, depending on how far a species is displaced from wind-energy facilities. The greatest concern with displacement impacts in western North America has been where facilities were constructed in native habitats such as grasslands or shrublands (Leddy et al. 1999, Mabey and Paul 2007).

Most studies on raptors at wind-energy facilities indicate displacement effects to be negligible. A before-after/control impact study of avian use at the Buffalo Ridge wind-energy facility in Minnesota found evidence that northern harriers (Circus cyaneus) avoided turbines on a small scale (< 100 m [328 ft] from turbines) and large scales (range of 105 - 5,364 m [345 – 17,598 ft]) in the year following construction (Johnson et al. 2000a). Two years following construction, however, no large-scale displacement was detected. The only published report of avoidance of wind turbines by nesting raptors occurred at the Buffalo Ridge facility, where raptor nest density on 101 mi² (261.6 km²) of land surrounding the facility was 5.94 nests/39 mi² (5.94 nests/101.0 km²) yet no nests were present in the 12 mi² (31.1 km²) facility itself, even though habitat was similar (Usgaard et al. 1997). At a facility in eastern Washington, raptors still nested in the study area at approximately the same levels after construction, and several nests were located within a half-mile (0.8 km) of turbines (Erickson et al. 2004). Howell and Noone (1992) found similar numbers of raptor nests before and after construction of Phase 1 of the Montezuma Hills facility in California, and anecdotal evidence indicates that raptor use of the Altamont Pass wind resource area in California may have increased since installation of wind turbines (Orloff and Flannery 1992, AWEA 1995). At the Foote Creek Rim wind-energy facility in southern Wyoming, one pair of red-tailed hawks nested within 0.3 miles (0.5 km) of the nearest turbine, and seven red-tailed hawk nests, one great horned owl (Bubo virginianus) nest, and one golden eagle nest located within one mile (1.6 km) of the facility successfully fledged young (Johnson et al. 2000b, Western EcoSystems Technology, Inc. [WEST] unpublished data). The golden eagle pair successfully nested a half-mile (0.8 km) from the facility for three different years after the project became operational.

Studies in western North America concerning displacement of non-raptor species have concentrated on grassland passerines and waterfowl. Wind-energy facility construction appears to cause small-scale local displacement of some grassland passerines and is likely due to the birds avoiding turbine noise and maintenance activities. Construction also reduces habitat effectiveness because of the presence of access roads and large gravel pads surrounding turbines (Leddy 1996, Johnson et al. 2000a). Leddy et al. (1999) surveyed bird densities in Conservation Reserve Program (CRP) grasslands at the Buffalo Ridge wind-energy facility in Minnesota, and found mean densities of 10 grassland bird species were four times higher at areas >180 m (591 ft) from turbines than they were at grasslands nearer turbines. Johnson et al. (2000a) found reduced use of habitat within 100 m of turbines by seven of 22 grassland-breeding birds following construction of the Buffalo Ridge facility. At the Stateline wind-energy facility in Oregon and Washington, use of areas <50 m from turbines by grasshopper sparrow (Ammodramus savannarum) was reduced by approximately 60%, with no reduction in use >50 m from turbines (Erickson et al. 2004). At the Combine Hills facility in Oregon, use of areas
within 150 m of turbines by western meadowlark was reduced by 86%, compared to a 12.6% reduction in use of reference areas over the same time period (Young et al. 2005a). Horned larks, however, showed significant increases in use of areas near turbines at both of these facilities, likely because this species prefers areas of bare ground such as those created by turbine pads and access roads (Beason 1995).

Shaffer and Johnson (2008) examined displacement of grassland birds at two wind energy facilities in the northern Great Plains. Intensive transect surveys were conducted on plots with and without turbines. The study focused on five species at two study sites, one in South Dakota and one in North Dakota. Based on this analysis, killdeer (Charadrius vociferous), western meadowlark, and chestnut-collared longspur (Calcarius ornatus) showed no avoidance of wind turbines. However, grasshopper sparrow and clay-colored sparrow (Spizella pallida) showed avoidance out to 200 m (656 ft).

At the Buffalo Ridge facility, the abundance of several bird types including shorebirds and waterfowl was significantly lower at survey plots with turbines than at reference plots without turbines, indicating that the area of reduced use was limited primarily to areas within 100 m of the turbines (Johnson et al. 2000a). These results are similar to those of Osborn et al. (1998), who reported that birds at Buffalo Ridge avoided flying in areas with turbines.

Populations of mountain plovers (Charadrius montanus) at the Foote Creek Rim wind-energy facility in Wyoming declined during construction but have slowly increased since, although not to the same level present prior to construction. It is not known if the initial decline or subsequent increase was due to presence of the wind-energy facility or to regional changes in mountain plover populations. Nevertheless, some mountain plovers have apparently become habituated to the turbines, as 11 of 28 nests found during surveys (39%) were located within 75 m (246 ft) of turbines (Young et al. 2005b).

Breeding dabbling ducks (mallard, blue-winged-teal [Anas discors], gadwall [A. strepera], northern pintail [A. acuta], and northern shoveler [A. clypeata]) were counted on wetland complexes at two wind-energy facilities and similar reference areas in North and South Dakota during the 2008 breeding season (Walker et al. 2008, unpublished report). Breeding duck numbers were similar between developed and undeveloped areas. The study is continuing through 2010 to further assess response of breeding ducks to wind-energy development.

The CPE wind energy facilities will be sited in vegetation communities common to the region, and other similar vegetation types are abundant. Furthermore, the actual area occupied by turbines and other infrastructure in a typical modern wind energy facility is only 5-10% of the total project area (BLM 2005). However, it is not known if displaced individuals simply move somewhere else and breed successfully, have reduced breeding success, do not breed at all, or some combination of the above. In addition, habitat fragmentation and disturbance from turbines and maintenance activities may make the entire wind-energy facility unsuitable for some species. If this occurs, a reduction in the number of breeding birds within the wind-energy facility and adjacent areas may occur, and the effect may be more pronounced in areas with concentrated facilities in circumstances where habitat is a limiting factor. However, the total area occupied by wind-energy facilities is only a small
fraction of the CPE (see Figure 1), and measurable population impacts are not likely for the entire region.

DISCUSSION

Mortality estimates for this analysis were based on species composition of fatalities found at 16 existing wind energy facilities in the CPE. Sample sizes for this analysis were relatively small for some groups. For example, we estimated ferruginous hawk mortality assuming that they would compose 5.7% of all raptor fatalities based on four ferruginous hawk fatalities out of 70 raptor fatalities found at the existing wind energy facilities. This ratio could easily change as additional fatality data are collected at new wind energy facilities in the CPE.

Our cumulative mortality estimates should be considered tentative, as no comparable fatality data exist for the large 2.0-3.0 MW turbines proposed for many of the future wind-energy facilities in the CPE. These estimates assume bird and bat fatality rates for a 3.0-MW turbine would be twice as high as a 1.5-MW turbine, which may not be accurate. Although the 2.0-3.0 MW turbines have a larger rotor diameter, which may increase collision risk to raptors, the rotor-swept area is higher off the ground and the turbine rotates at slower speeds, which may actually reduce risk to some raptors. Based on an analysis of avian fatality data at wind farms with turbines ranging in size from 0.04–1.8 MW, tower heights ranging from 24–94 m and rotor diameters ranging from 15–80 m, Barclay et al. (2007) concluded that avian fatality rates were not affected by any of these parameters. Therefore, inflating our estimates to account for larger turbines may lead to over-estimates of avian mortality.

This cumulative effects analysis was based largely on results of existing studies of wind-energy facilities in the region, and in particular monitoring studies that estimated the direct impacts of a particular wind-energy project. The overall design for these studies incorporates several assumptions or factors that affect the results of the fatality estimates. First, all bird casualties found within the standardized search plots during the study periods were included in the analyses. It is assumed that carcass found incidentally within a search plot during other activities would have been found during a standardized carcass search. Second, it was assumed that all carcasses found during the studies were due to collision with wind turbines. True cause of death is unknown for most of the fatalities. It is highly likely that some of the casualties included in the data pool for the various projects were due to natural causes or background mortality such as predation, disease, other natural causes, or manmade causes such as farming activity or vehicles on county/project roads. The overall effect of these assumptions is that the analyses provide a conservative estimate (an overestimate) of mortality.

This cumulative impacts analysis assumed that up to 6700 MW of wind energy could be developed in the CPE. However, based on recent estimates by the Northwest Power and Conservation Council (NPCC), which recognize constraints on wind development, such as transmission capacity, the NPCC projects that 5577 MW of wind energy development will be installed by the year 2013 (Jeff King, Senior Resource Analyst, presentation to the Northwest Wind Integration Forum Steering Committee, January 7, 2010). Because our estimates of bird and bat fatalities assuming that 6700 MW of wind energy would be developed are likely
overestimates, for comparison purposes we also derived estimates assuming that 5577 MW of wind energy would be developed (Table 8).

A few studies of wind-energy facilities in other regions of the country have provided information on background mortality. During a four-year study at Buffalo Ridge, Minnesota, 2482 fatality searches were conducted on study plots without turbines to estimate reference mortality in the study area. Thirty-one bird fatalities comprising 15 species were found (Johnson et al. 2000a). Reference mortality adjusted for searcher efficiency and carcass removal for the study was estimated to average 1.1 fatalities per plot per year. At a second study, pre-project carcass searches were conducted at a proposed wind-energy facility in Montana (Harmata et al. 1998). Three bird fatalities were found during eight searches of five transects, totaling 10.94 miles (17.61 km) per search. On average, approximately 1.12 miles (1.8 km) of transect are searched within each turbine plot in the referenced studies for the CPE (Table 2). The amount of transect searched at the Montana site per search was equivalent to searching approximately seven to nine turbines for the regional studies. The background estimate for observed mortality would be approximately 0.33 per turbine plot per year, unadjusted for scavenging and searcher efficiency. The background mortality information from the Minnesota and Montana studies suggests that the estimates of bird mortality include some fatalities not related to turbine collision, and this factor alone would lead to an over-estimate of actual bird collision mortality for wind-energy facilities.

Avian population estimates used in this analysis relied on breeding bird survey (BBS) data, and some of these estimates had relatively large standard errors. Thogmartin et al. (2006) reviewed the population estimation approach used by Blancher et al. (2007) and concluded that because BBS data were designed to detect long-term population trends, use of these data for estimating population sizes may be questionable. Regardless of these concerns, in order to estimate cumulative impacts, information on sizes of affected populations is required, and the population estimates provided by Blancher et al. (2007) are the only ones available for the CPE.

Finally, this cumulative impacts assessment only examined cumulative impacts of birds and bats due to wind energy development in the CPE. Wind energy development is only one factor affecting wildlife populations in the CPE, and is likely minor compared to other past, present, and future actions in the CPE, including large-scale conversion of native shrublands and grasslands to crop land; expansion of urban areas and rural subdivisions; road and highway construction; energy development, including dams for hydropower; and increases in other infrastructure, such as communication towers and power lines. For example, a review conducted by Erickson et al. (2001) found that wind energy contributes only a minor fraction of the overall avian collision mortality in the US due to powerlines, roads, communication towers and other structures. The ability to estimate wind energy development impacts on wildlife is unique because several studies have been conducted in the CPE to quantify bird and bat impacts. Similar estimates of bird and bat impacts due to direct mortality and loss or fragmentation of habitat caused by other activities are not available.

1.0 INTRODUCTION AND BACKGROUND

Over the last decade, there has been a surge of interest in wind power development in Oregon and Washington along the Columbia River corridor and within the Columbia Plateau physiographic region (ecoregion). A central issue for wind power developments is the potential impacts to avian and bat resources, and in particular direct impacts such as avian or bat fatalities. Wind power proposals are commonly reviewed by natural resource agencies, private conservation groups, permitting authorities and other stakeholders. Frequently, baseline studies are conducted that are designed to estimate avian presence and abundance at proposed development sites for use in the impact assessment and siting of the project followed by monitoring studies post construction which are designed to measure impacts from the project. As more wind power projects are constructed along the Columbia River and surrounding region, cumulative impacts from multiple projects have become a concern and are important to consider.

The proposed Shepherds Flat wind power project is located in Gilliam and Morrow Counties, in north-central Oregon. The proposed project would have from 300-326 turbines, each with a capacity of 2.3-2.5 megawatts (MW), for an overall project capacity of 750 MW. The total proposed project area using the lease area boundaries is approximately 31,270 acres (48.9 mi²). The project boundary comes within 1 mile of the Columbia River to the north. Land use is typical of other existing and proposed wind projects in the region and consists primarily of dryland agriculture, of which small amounts have been converted to Conservation Reserve Program (CRP) lands, and areas of native grassland rangeland.

Most wind power development in northern Oregon and southern Washington has been within the Columbia Plateau Level III Ecoregion (Thorson et al. 2003; Figure 1). The Columbia Plateau was historically characterized by open, arid shrub-steppe and grassland-steppe habitats. The current predominant land use of the Ecoregion is dryland agriculture, CRP lands, and rangeland. Precipitation through the region is 6-12 inches per year (Thorson et al. 2003). Surrounding ecoregions are more mountainous, receive more precipitation, and are more forested than the Columbia Plateau. While the Columbia Plateau has less vegetative strata than surrounding ecoregions, and is an excellent place for wind power development, plant and animals species that are specialized for this type of habitat may be recipient of a larger portion of the cumulative impacts from wind development.

2.0 METHODS

This report is intended to provide a broad, qualitative analysis using existing public information about existing wind projects and wind project proposals in the region and results of monitoring (fatality) studies to compile a cumulative impact analysis for avian and bat resources. The analysis relies heavily on existing information from studies in the Columbia Plateau Ecoregion. Information about wind project proposals was gathered from a variety of sources such as federal and state agencies (e.g., BPA, Oregon EFSC), permitting agencies (e.g., Klickitat County), non-
profit renewable energy advocates (e.g. Renewable Northwest Project), and other public sources such as internet resources. Basic information such as the proposed capacity, turbine size and number, and location about each project identified was gathered and summarized to the extent possible. In many cases the actual boundary of the proposal could not be identified and only a general location was known.

The general approach to the cumulative effects analysis was to summarize results of fatality monitoring studies at operational wind projects within the same ecoregion, and then use the results to estimate impacts for all constructed and proposed wind projects within approximately 100 km of the proposed Shepherds Flat project (Figure 1). The 100km buffer is somewhat arbitrary but due to similarities of habitat and land use throughout the whole Columbia Plateau ecoregion the resources potentially impacted by wind projects are similar for all projects. The Vansycle and Combine Hills wind projects occur just outside a 100km distance from Shepherds Flat and are included in the analysis (Figure 1).

This cumulative effects analysis considers data from seven projects in the Columbia Plateau ecoregion where monitoring for fatalities has occurred. Predominant vegetation type and land use for all the projects where monitoring occurred is similar (dryland agriculture, grassland and shrub-steppe rangeland), and the fatality and avian survey data were all collected using similar methods. The data sets used in this report were collected using similar methods, where observed fatality rates calculated from standardized carcass searches were adjusted for searcher efficiency and carcass removal biases. The analysis operates under the assumption that the avian and bat communities are similar across all projects because of habitat and land use similarities throughout the ecoregion, and thus applicable to the new proposed projects in this same ecoregion. Details about results, methods, and estimates of potential avian impacts from each individual project are available in the referenced project reports.
Figure 1. Level III ecological regions and wind power development projects in southeastern Washington and northeastern Oregon.
3.0 RESULTS

3.1 Study Area and Wind Projects

As of early 2007, 12 wind projects were in operation in the Columbia Plateau Ecoregion and 10 of these were in operation within approximately 100 km of the proposed Shepherds Flat project (Figure 1, Table 1). Two operating facilities, Hopkins Ridge and Wild Horse, are about 180 km to the east and 140 km to the north respectively and still within the Columbia Basin ecoregion.

Currently, up to 19 other wind power projects are planned or being constructed within approximately 100 kilometers of the Shepherds Flat project (Figure 1, Table 1). While the capacity and number of turbines could not be determined for all proposals, when completed and including the Shepherds Flat project, they could result in up to 1600 additional turbines in the region, contributing over 4060 MW of power (Table 1).

Most of the operating facilities have had or will have some sort of avian or casualty monitoring associated with them and post-construction fatality monitoring data are available from five of the wind projects within approximately 100km of Shepherds Flat and six over all (Table 2). The Vansycle project was constructed in 1998 and avian/bat fatalities were monitored during 1999 (Erickson et al. 2000). The Stateline project was constructed in several phases starting in 2001. Avian observations and fatality monitoring were conducted at Stateline from 2001-2003 (Erickson et al. 2004). Klondike I was completed in 2001 and fatalities were monitored for one year following construction (Johnson et al. 2003) Combine Hills I was constructed in 2003 and fatality monitoring results are available for 2004 (Young et al. 2005). Nine Canyon I became operational in fall 2002 and fatalities were monitored for one year (Erickson et al. 2003). Nine Canyon II was online in 2004 but also only underwent some short term monitoring for one season. The Hopkins Ridge project was completed in 2005 and monitored in 2006 (Young et al. 2007). The Condor project was online by June 2002 and a short term non-standardized monitoring study took place in 2003\(^1\). Construction for Leaning Juniper was partially completed in 2006, with the second half of the project scheduled to come on line in 2007. The Big Horn project was completed in 2006. Both of these projects are being monitored in 2007.

For each of the individual study areas from which fatality results are available, the predominant land use was a mosaic of agriculture, mainly dryland wheat farming, and grassland or shrub-steppe rangeland used for livestock grazing. In general, the region where future wind power projects are being planned is similar in vegetation types although for any given project the amount of each type varies (Quigley and Arbelbeide 1997, Figure 2). It is assumed for the analysis that results from the existing studies, which are similar, would be applicable to new proposed projects.

\(^1\) Monitoring at the Condon wind project took place for less than one year in 2002-2003 (Fishman 2003). This study did not use similar methods to the other studies and was not as rigorous. No searcher efficiency or carcass removal surveys were conducted so the reported results are simply observed number of fatalities for the study and not comparable to the other studies.

*a not adjusted for searcher efficiency or scavenger removal; study methods differed from other projects and were not as rigorous; therefore this estimate should be regarded as a minimum mortality estimate and it was not used in calculation of the mean values.

3.2 Direct Impacts to Birds

Annual avian mortality estimates at wind farms in the Columbia Plateau Ecoregion ranged from 0.9 to 2.9 birds per MW (Table 2). The average for six projects with comparable data collection methods was 1.9 avian deaths/MW/year. All constructed, planned, and under construction projects within 100km and including Shepherds Flat would contribute about 4060 MW of power. Assuming that mortality rates are representative of the region, new wind power generation could cause between approximately 3,650 and 11,775 and on average 7,715 avian deaths per year in the region.

Raptors

At modern wind power projects in the Columbia Plateau Ecoregion, raptor species generally constitute only a small portion of avian use, ranging from 0.26 to 0.64 observation per 20-min survey. Raptor mortality has also been low ranging from 0 to 0.14 raptor fatalities per MW per year. An added 4060 MW of capacity in the region could result in between 0 and 568, and on average about 200 raptor deaths per year.

Red-tailed hawk, American kestrel, and northern harrier account for most of the raptor use at other projects where avian use was studied (see Erickson et al 2001, 2002). In the winter, rough-legged hawk and red-tailed hawk account for majority of the raptor use. If it is assumed that raptor use is correlated with mortality, these species are expected to be the raptor species with the highest collision risk across the projects. The potential exists for other species to collide with turbines,
including Swainson’s hawk, ferruginous hawk, turkey vulture, golden eagle, Cooper’s hawk, sharp-shinned hawk, prairie falcon, and bald eagle; however, the mortality risk associated with these species is expected to be lower than the mortality for red-tailed hawks and American kestrel due to the lower use by these species in general. In addition, American kestrel and red-tailed hawk have been the most common fatality at regional wind projects (Table 3; Erickson et al. 2001, 2004, Young et al. 2007). Common owl species such as great-horned, which are typically not effectively surveyed during the day, may also be at risk of collision, although short-eared owl has been the only owl species fatality recorded at the regional wind projects (Table 3). While use is often high for turkey vultures, they appear less susceptible to collision than most other raptors (see Orloff and Flannery 1992, Erickson et al. 2001). In addition, there have been very few northern harrier, ferruginous hawk, rough-legged hawk, and Accipiter species fatalities recorded at wind projects (Table 3, Erickson et al. 2001, 2002).

**Passerines**

Passerines have been the most abundant avian fatality at wind projects studied (see Erickson et al. 2000, 2001, 2002, Johnson et al. 2002, Young et al. 2003, 2005, 2007), often representing more than 80% of the avian fatalities. For projects in the Columbia Plateau Ecoregion on average approximately 69% of the avian fatalities have been passerines (Table 4). Both migrant and resident passerine fatalities have been observed, with migrants generally making up 20-30% of the avian fatalities. Assuming that 69% of all bird mortality would be passerine fatalities between approximately 2,518 and 8,125 and on average 5,323 passerine deaths per year in the region would occur. Some impacts are expected for nocturnal migrating species, however, impacts are not expected to be great for the Columbia Plateau Ecoregion. Estimates for nocturnal migrant mortality at the regional wind projects have ranged from 0.27 to 0.73 per MW per year (Table 2). Assuming these estimates are representative of Columbia Plateau wind projects, between approximately 1,090 and 2,960 nocturnal migrant fatalities would be expected if 4060 MW of wind power were constructed.

Passerine species most common to the project sites will likely be most at risk, including horned lark, western meadowlark, and European starling, however, there is generally little concern over potential mortality of this non-native, non-protected species. Horned larks have been the most commonly observed fatality at several wind projects, including Vansycle, Combine Hills, and Stateline (Table 3, Erickson et al. 2003, Young et al. 2005, Erickson et al. 2004) and represent approximately 35% of the avian fatalities in the Columbia Plateau ecoregion at wind projects. Golden crowned kinglet, a tree/forest dwelling species, have been recorded as fatalities at a few projects and are generally considered migrants.

**Upland gamebirds**

For projects in the Columbia Plateau Ecoregion, upland gamebirds have composed a higher percentage of avian fatalities than in other regions of the U.S., approximately 18% of all avian fatalities (Table 4). Three introduced species, ring-necked pheasant, chukar, and gray (Hungarian) partridge are the most commonly found non-passerine fatalities (Table 3). Estimates for upland game bird mortality in the Columbia Plateau Ecoregion have varied from 0.27 to 0.47 per MW per year. Provided these estimates are representative, between 1,090 and 1,910 upland gamebird fatalities would be expected per year for 4060 MW of wind power.

### 3.3 Direct Impacts to Bats

Results of fatality monitoring for the Columbia Plateau Ecoregion wind projects indicate mortality ranges of approximately 0.63 to 2.46 bats per MW per year (Table 5). Based on these results, and considering the similarities in the characteristics of the project areas and other regional projects, a conservative estimate of total bat mortality would be between 2,550 and 9,990 bats per year, assuming 4060 MW of wind power is constructed.

<sup>1</sup> Most reports do not provide number per MW of energy produced so this number was calculated based on the mortality per turbine and capacity of turbines studied.

Only four species of bat fatalities have been documented for six wind projects monitored in the Columbia Plateau Ecoregion (Table 6). The vast majority of the fatalities were composed of two species: silver-haired bat (48%) and hoary bat (46%), two species of foliage (tree) dwelling migratory bats (see Erickson et al. 2003, 2004; Young et al. 2005, Johnson et al. 2003, Young et al 2007). Monitoring studies at other wind projects nationwide have documented impacts to bats with some common results for all regions (Johnson 2005). The species at highest risk appear to be foliage dwelling (forest, trees) fall migratory species. The annual period when most bat fatalities occur is in August and September. Hoary and silver-haired bats are wide spread across North America and breed into the boreal forests regions of Canada and migrate south to winter in the southern U.S., Mexico, and potentially further south in Central America. Many bats will migrate short distances to suitable hibernacula for the winter; however, short distance migrant species do not appear to be at as great a risk based on the monitoring studies results.

Bat foraging areas such as riparian zones, shrublands, streams, and other water sources are generally limited in the Columbia Plateau Ecoregion and usually confined to river and stream corridors. The sites chosen for wind development in the ecoregion generally have few bat
foraging or concentration areas. At several wind projects studied in the U.S., bat collision mortality during the breeding season was far less, despite the fact that relatively large populations of resident bats of several species were documented in proximity to the wind plant (see Gruver 2002; Johnson et al., 2002; Johnson 2005). Based on these studies, it appears that wind projects, especially those in open habitats, pose little risk to non-migratory bat populations.

3.4 Habitat Impacts

Grassland and shrub-steppe habitat is one of the most abundant habitat types in Eastern Oregon and Washington, but it is also highly subjected to development and conversion to agriculture (Johnson and O’Neil 2001). In addition to potentially thousands of new vertical structures, added wind generation in the region will result in more roads (mostly dirt and gravel) and increased human activity due to turbine construction and maintenance. Most habitat impacts will be to already heavily disturbed agriculture fields and moderately disturbed grazing/rangeland. The percent of direct impacts actually occurring in grassland or shrub-steppe habitat are difficult to predict and would be based on individual project design and layout.

Because of the location of the proposed wind projects (Figure 2, Table 1), it is expected that the majority of habitat impacts will occur in dryland agriculture vegetation. Under a set of assumptions about impacts and project location, the amount of cumulative impacts to vegetation communities can be estimated. Assuming that: (1) on average the permanent impacts associated with a turbine and the associated roads are between 1.5 and 2.5 acres per turbine; (2) 25% of a project layout occurs in non-agricultural vegetation types, which in many cases is a drastic overestimate; and (3) 1.5-2.5 MW turbines are used for the proposed build out identified (Table 1), then between 630 and 1750 acres of non-agricultural vegetation type, primarily grassland shrub-steppe vegetation, would be lost in the Columbia Plateau Ecoregion with 4060 MW of wind projects. These impacts would be spread over a large area geographically (see Figure 1) and are considered an overestimate because of efforts to locate projects in agricultural vegetation types. On a local (project) scale, these impacts are generally on the edge of native vegetation areas where they abut agriculture fields.

While the Columbia Plateau covers a large area, and characteristic grassland shrub-steppe habitat is widespread, it is also heavily fragmented by agricultural activities. Species that depend on native habitat face physical and ecological barriers within the region and at the region’s edges. The Columbia River and other smaller rivers in the area cut deep canyons and present linear alteration to the general physiography and potential barriers to some animal species movement. Large swaths of agricultural land are less obvious, but may pose significant obstacles to small or less mobile animals. While many birds are not impeded by such physical barriers, some smaller, habitat specific birds that depend on brushy habitats for cover could be affected by such habitat fragmentation. Habitat specialists and obligates such as sage-grouse (*Centrocercus urophasianus*) and sage sparrow (*Amphispiza belli*) require large tracts of continuous sage habitat (Johnson and O’Neil 2001), which is largely missing from the Columbia Plateau, and the range for these species in the Columbia Plateau is already severely restricted. Assuming that agricultural vegetation types are not critical wildlife habitat, habitat loss impacts are not expected to be a significant loss to any given species.
4.0 DISCUSSION

This cumulative effects analysis was based largely on results of other studies of wind projects in the region and in particular monitoring studies that estimated the direct impacts of a particular wind project. The overall design for these studies incorporates several assumptions or factors that affect the results of the fatality estimates. First, all bird casualties found within the standardized search plots during the study periods were included in the analyses. It is assumed that carcass found incidentally within a search plot during other activities would have been found during a standardized carcass search. Second, it was assumed that all carcasses found during the studies were due to collision with wind turbines. True cause of death is unknown for most of the fatalities. It is highly likely that some of the casualties included in the data pool for the various projects were due to natural causes or background mortality such as predation, disease, other natural causes, or manmade causes such as farming activity or vehicles on county/project roads. The overall effect of these assumption is that the analyses provide a conservative estimate (an over estimate) of mortality due to the studied wind project.

A few wind studies in other regions of the country have provided information on background mortality. During a four-year study at Buffalo Ridge, Minnesota, 2,482 fatality searches were conducted on study plots without turbines to estimate reference mortality in the study area. Thirty-one (31) avian fatalities comprising 15 species were found (Johnson et al. 2000). Reference mortality adjusted for searcher efficiency and carcass removal for the study was estimated to average 1.1 fatalities per plot per year. At a second study, pre-project carcass searches were conducted at a proposed wind project in Montana (Harmata et al. 1998). Three bird fatalities were found during 8 searches of 5 transects, totaling 17.61 km per search. On average, approximately 1.8 km of transect is searched within the turbine plots in the referenced studies for the Columbia Plateau region (Table 2). The amount of transect searched at the Montana site per search was equivalent to searching approximately 7-9 turbines for the regional studies. The background estimate for observed mortality would be approximately 0.33 per turbine plot per year, unadjusted for scavenging and searcher efficiency. The background mortality information from the Minnesota and Montana studies suggests that the estimates of bird mortality include some avian fatalities not related to turbine collision, and this factor alone would lead to an over-estimate of true avian collision mortality for wind projects.

It should also be noted that the fatality estimates may vary from the expected range based on many factors that may influence bird and bat use of a project site such as habitat, topography, foraging areas, migratory patterns, as well as project characteristics such as turbine size, met towers, proximity to high bird use areas and other site specific and/or weather variables. It is difficult to determine the influence these parameters have on impacts from wind projects; however, because of the general similarities of results from the monitoring studies within the Columbia Plateau Ecoregion (see Table 2) it is generally believed that future direct impacts from new wind development in the region are also likely to be similar.
4.1 Significance of Impacts to Birds

Despite several thousand bird fatalities from 4060 MW of wind power, these impacts are divided across numerous species and groups of species and also across seasons, and thus the overall mortality to any given species or population of a species is substantially less and not expected to be significant.

Passerines
For most studies that have occurred in agricultural settings, a few common species make up the majority of bird observations and fatalities at the site, however, a variety of other species, including migrants, have been recorded as fatalities but typically in low numbers and frequency. The majority of avian deaths (69%) due to wind power facilities in the Columbia Plateau region were of common passerines in mixed agriculture and grassland habitat (see Table 3). Horned larks are the most common fatality at most of the projects studied. For example at the Stateline, Combine Hills, Nine Canyon I, horned larks were 39%, 41%, and 47% of all avian fatalities, respectively and a much higher percentage of the passerine fatalities. Other shrub-steppe and open country passerines such as western meadowlarks and European starling were also found regularly. For example, European starling made up 18% of the fatalities at the Hopkins Ridge project (Young et al. 2007).

Given that most of the mortality will be common species with widespread distribution and large populations, impacts are expected to be to individuals and not populations. For example, over all passerines recorded during the regional monitoring studies, horned lark made up over half (51%) of the fatalities. Assuming this pattern holds for the regional wind development, it could be expected that on average there would be 2,715 horned lark fatalities per year. Local populations of horned larks are difficult to define because of the vast amount of suitable habitat for this species in the Columbia Plateau. Based on data from the USGS Breeding Bird Survey routes in the Columbia Plateau, the long term average was 50.3 horned larks detected for 71 routes in the ecoregion (Saur et al. 2005). Each BBS route covers 25 miles with a survey plot radius of 0.25 mile for a total survey area of roughly 12.5 square miles or 8,000 acres. The total area surveyed in the 71 routes (~568,000 acres) represent ~2.8% of the 20,280,000 acre Columbia Plateau. The annual average observed number of horned larks for the 71 routes was approximately 3,573. Assuming this represents 2.8% of the breeding horned lark population in the Columbia Plateau, the total would be approximately 127,500 horned larks. This is a likely a minimum estimate because horned larks are a small bird that is detected with relatively low probability beyond 200 m. If it is further assumed that the 2,715 horned lark fatalities are spread equally over the year, then roughly one-quarter of these (~679) would be during the breeding season. This represents approximately 0.5% of the breeding horned larks and is not considered significant. It is likely that other background mortality of breeding horned larks is greater than this estimate.

While this example represents a plausible means of addressing potential population impacts under a number of assumptions, it illustrates the low level of effect on the common grassland/agricultural species that have been the most impacted. Similar examples could be used for the other species which illustrate lower effects. For example the BBS data indicates a long term average of 77.61 western meadowlarks for routes in the Columbia Plateau (Saur et al. 2005). Western meadowlark represents approximately 6% of the passerine fatalities at wind projects. Based on similar
calculations the impact on the western meadowlark breeding population in the Columbia Plateau would be minor and insignificant. The number of fatalities from other species are even fewer (see Table 3) and unlikely to have any population effects.

**Nocturnal Migrants**
In general, while modern turbines are getting taller, new wind projects do not appear to have a large impact on migrant birds. Results of marine radar surveys for proposed wind projects have indicated that the vast majority of nocturnal migrants fly at altitudes that do not put them at risk of collision with turbines (Young and Erickson 2006). Also, there have been only two multiple individual mortality events during a migration season reported at newer wind projects in the U.S. At Buffalo Ridge, Minnesota, fourteen migrating passerine fatalities (vireos, warblers, flycatchers) were observed at two turbines during a single night in May 2002 (Johnson et al. 2002), and 33 migrating passerine fatalities (mostly warblers) were observed near one turbine and a well-lit substation at the Mountaineer, West Virginia, wind project in May 2004 (Kerns and Kerlinger 2004). In general for wind projects in the Columbia Plateau, approximately 25% of the fatalities have been considered migrants spread over many species. The most common migrant fatality was golden-crowned kinglet (Table 3). Approximately 9% of the passerine fatalities were of this species. Golden-crowned kinglets are typically associated with tree or wooded habitats during the breeding season so it is assumed that many of the impacted individuals were from surrounding more mountainous ecoregions or populations further north (e.g., Canada). As with horned lark, estimating the potential population size from which these birds came requires a number of assumptions. However, while it is unknown, it is possible that the individual fatalities came from multiple populations in surrounding or more northern ecoregions, thus diluting the impacts on any one population. Other potential migrant species were found in lower numbers. Cumulatively the impacts to migrants would be spread over a much larger population base and are not considered significant.

**Raptors**
Red-tailed hawk and American kestrel account for more than 69% of the raptor fatalities recorded at the regional wind projects studied (see Table 3). Assuming this trend holds true for all proposed wind projects in the Columbia Plateau, it would be expected that on average 70 red-tailed hawk and 70 American kestrels would be killed each year. Following a similar analysis as that used for horned lark (above) it would be expected that approximately 18 red-tails and kestrels fatalities would occur during the breeding season. An estimate of the breeding population in the Columbia Plateau based on the BBS long-term average data is approximately 6820 breeding red-tailed hawks and 6288 breeding American kestrels. The impact to the breeding population would represent approximately 0.26% and 0.28% respectively. Background mortality for these species is likely higher than this estimate and it is considered insignificant. The other species of raptors have been impacted far less and would represent a much smaller number of fatalities.

**Upland Gamebirds**
Upland gamebird species represent a higher percentage (18%) of the avian fatality pool in the Columbia Plateau than in other regions in the U.S., although it is believed that many of the fatalities that are recorded are not wind turbine related. A large percentage of the upland gamebird fatalities are feather spots, suggesting the possible cause of death was predation or other non-turbine related cause. The species impacted, ring-necked pheasant, gray partridge, and chukar are introduced species common in
mixed agricultural native grass/steppe habitats. Habitat throughout the Columbia Plateau is highly suitability for these species and the large populations likely influence the higher mortality rate for the regional wind projects. As with non-native (non-protected) passerine species, there is generally low concern over impacts to upland gamebirds. These species are regulated by state agencies as game species. Impacts to these species are not expected to be significant and given the vast amounts of suitable habitat and other impacts to these species (i.e., hunting) it is unlikely that fatalities from wind development to these species would be significant.

### 4.2 Significance of Impacts to Bats

Unlike with birds, there is little information available about populations of bat species. For most species that are not threatened or endangered and have large distributions, very little is known about potential numbers that exist. Results of monitoring studies across the U.S. and Canada have found similar trends in impacts such as risk to bats from wind turbines is unequal across species and across seasons. The majority of bat fatalities at wind projects in the U.S. and Canada have been foliage/tree or forest dwelling long-distance migrant species. Species in the *Lasiurus* genus, hoary bat (*L. cinereus*) in the west and red bat (*L. borealis*) in the east, and silver-haired bats (*Lasionycteris noctivagans*) are the most abundant fatalities found at wind projects. Less common fatalities are of big brown bats and *Myotis* species. Numerous studies across the U.S. and Canada have shown this trend (see Johnson 2005). The highest mortality occurs during what is believed to be the fall migration period for bats from roughly late-July through September. Numerous studies across the U.S. and Canada have also shown this trend (see Johnson 2005). Much lower mortality rates, and particular in the Columbia Plateau Ecoregion, occur in the spring and summer.

More recently however, studies at different location in the U.S. and Canada, appear to indicate that bat mortality is not related to site features or habitat and dissimilar results for ecologically similar projects have been found. While it is hypothesized that eastern deciduous forests in mountainous areas may be the highest risk areas, higher bat mortality has also occurred at wind projects in prairie/agricultural settings (Alberta, Canada) and mixed deciduous woods and agricultural settings (Maple Ridge, New York). For example, a wind project in dryland agricultural prairie type habitats in southern Alberta has reported fairly high observed bat mortality (not corrected for searcher and carcass removal biases) of 12-15 bats per turbine per year or 7-8 bats per MW per year (Baerwald 2006). In contrast, other nearby (within 25 km) wind projects to that site have reported similar bat mortality (1-2 bats per MW per year) to the wind projects studied in the Columbia Plateau Ecoregion (Baerwald, pers. comm.).

Bat mortality in the Columbia Plateau Ecoregion would involve primarily silver-haired and hoary bats (see Table 6), and no impacts to threatened or endangered bat species are anticipated. The regional monitoring studies suggest resident bats do not appear to be significantly affected because in general, very low numbers of resident bat species have been observed fatalities. Hoary bats and silver-haired bats generally occupy forested or treed habitats during the breeding season – habitat distinctly lacking and localized in the Columbia Plateau Ecoregion. Most mortality is observed during the fall migration period and of these migrant species. The significance of this impact on hoary and silver-haired bat populations is difficult to predict, as
there is very little information available regarding the overall population size and distribution of the bats potentially affected. Hoary bat and silver-haired bats are widely distributed in North America. In general, mortality levels on the order of 1-2 bats per turbine or per MW are thought to be on individuals and not significant to populations, however, cumulative effects may have greater consequences for long-lived low-fecundity species such as bats. Unlike many avian species that may have multiple clutches of multiple young per year, hoary bats and silver-haired bats likely only raise one or two young per year and only breed once per year (Shump and Shump 1982, Kunz 1982). Bats tend to live longer than birds, however, and may have a long breeding lifespan. The impact of the loss of breeding individuals to populations such as these is generally unknown but may have greater consequences.

Since it is most likely breeding populations from surrounding mountainous/forested ecoregions or from more northern area (e.g., Canada) that are affected at the Columbia Plateau wind projects during the fall migration, the dynamics of these populations would need to be know to predict population effects. If these populations are large and stable the level of impact is not expected to be significant. However, if population trends are decreasing the added impact from wind development may continue to cause population declines. This information is generally unknown and future study is needed before the significance of the impacts can be estimated.

Olympia, WA 98504-3172

Subject: Certificate of Land Use Consistency Review for Whistling Ridge Wind Energy Project

Dear Mr. Fiksdal:

Skamania County has reviewed the Application for Site Certification that was submitted to the Washington State Energy Facility Site Evaluation Council on March 10, 2009 for the Whistling Ridge Energy Project. The application was reviewed to determine if the project was consistent or inconsistent with applicable County land use plans and zoning ordinances.

If the application had been submitted to the County, the project would require the following county issued reviews and permits: a SEPA Review, a Conditional Use Permit (only for the portion of the project located within the zoned area), a National Scenic Area (NSA) Permit (only for the portion of the project related to road and intersection widening that is located within the NSA), Building Permits, Critical Area Review (outside of the NSA), On-site Septic Permit, Well Drilling Inspection, and a Water Availability Verification Evaluation (W.A.V.E) Application. However, the final requirements and conditions of approval for the project would be determined by EFSEC during their review process.

Zoning Update:

In December 2007, the County began work to revise Title 21, the current Zoning Ordinance. Part of the update process was to try and incorporate small and large-scale energy facilities into the County regulations. The County’s SEPA decision (A Determination of Non-Significance) for the zoning draft was appealed by two organizations. In their appeal, the organizations were requesting the County to prepare an EIS for non-project actions that may lead to significant adverse impacts. On February 19,
2009, the Hearing Examiner decided in favor of the appellants, the Determination of Non-Significance was reversed, and remanded to the County for preparation of an EIS. Since this decision, the map and text updates for the Zoning Ordinance project have permanently been placed on hold. It has not been decided whether or not the County will continue with this project or start from scratch when the zoning update process resumes. There is no scheduled time to return to the zoning project. The current adopted zoning is what applies to this project, drafts of “proposed” or “future” zoning ordinances or any Hearing Examiner review of such documents have no basis or bearing on this application before EFSEC. Only 7 of the potential 50 turbines are even located within an area that has a zoning classification. The remainder of the project area is unzoned.

Consistency Review:

After reviewing the location of the proposed Whistling Ridge Wind Energy Facility project I find that the project is consistent with the following land use codes and maps: SCC Title 21 Zoning Code, SCC 21A Critical Areas, Title 24 Clearing and Grading, the Comprehensive Plan, and resource maps. The project is not within SCC Title 20 (Shorelines) jurisdiction.

After reviewing the location of the proposed road improvements, SCC Title 22 Columbia River Gorge National Scenic Area Ordinance, and the resource maps, I find the road improvement portion of the application consistent with SCC Title 22 with conditions of approval. I further find that similar road improvement projects (road widening, realignments, etc.) have been found consistent with SCC Title 22 in the past.

For more detailed findings see the attached staff reports.

Sincerely,

Karen A. Witherspoon, AICP,
Community Development Department Director

Certificate of Land Use Consistency Review for Whistling Ridge Wind Energy Project
RESOLUTION 2009-22

(Certification of Land Use Consistency Review for Whistling Ridge Wind Energy Project)

WHEREAS, Whistling Ridge Energy Project, LLC ("Applicant") filed an Application for Site Certification ("ASC") to the Washington Energy Facility Site Evaluation Council ("EFSEC") on March 10, 2009 for the Whistling Ridge Energy Project ("Project") pursuant to RCW 80.50; and

WHEREAS, EFSEC has assumed lead agency status pursuant to the State Environmental Policy Act, RCW 43.21C for the environmental review of this Project. Skamania County anticipates participating in the SEPA process; and

WHEREAS, the Skamania County Community Development Director reviewed the ASC to determine the project’s consistency with applicable County land use plans and zoning ordinances and prepared a Certificate of Land Use Consistency; and

WHEREAS, the Board of County Commissioners have reviewed the Community Development Director’s Certification of Land Use Consistency; and

WHEREAS, the Board of County Commissioners on May 5, 2009 considered the Community Development Director’s determination at a regularly scheduled, public meeting; and

WHEREAS, due notice of the Commissioner’s meeting set forth above has been given as required by law; and

WHEREAS, the development of the Whistling Ridge Energy Project, if approved, will be specifically governed by a Site Certification Agreement signed by the Governor and the Applicant, including conditions of approval developed through the upcoming public process, including SEPA review; and

WHEREAS, more detailed findings of consistency are included in the Community Development Director’s Certificate of Land Use Consistency, which is attached hereto and is incorporated herein by reference as if set forth in full; and

NOW THEREFORE, BE IT RESOLVED, the Board of County Commissioners, after due deliberation, adopts the Certificate of Land Use Consistency and resolves that the Whistling Ridge Energy Project is consistent with the Skamania County land use plans and applicable zoning ordinances. A representative for Skamania County appointed by the Board of Commissioners is serving as a member of the Siting Council. Consequently, Skamania County does not, at this time, make any findings or determination regarding compliance with any other regulatory requirements or siting standards, and any potential conditions of approval recommended by Skamania County will be made at such time as the SEPA review is completed and after public meetings and hearings have been duly conducted by EFSEC, in accordance with Chapter 80.50 RCW.
PASSED IN REGULAR SESSION this 5th day of May 2009.

BOARD OF COUNTY COMMISSIONERS
SKAMANIA COUNTY, WASHINGTON

Chairman

Commissioner

Commissioner

ATTEST:

Clerk of the Board

APPROVE AS TO FORM ONLY:

Prosecuting Attorney
STAFF REPORT FOR LAND USE CONSISTENCY REVIEW

I. SUMMARY OF PROPOSED ACTION (Project description)

This Land Use Consistency Review Staff Report is to address the application for the Whistling Ridge Energy Project to the Washington State Energy Facility Site Evaluation Council.

As proposed by the application submitted March 10, 2009 to the Energy Facility Site Evaluation Council (EFSEC), Jason Spadaro President of SDS Lumber Co, and of Whistling Ridge Energy LLC, is proposing a facility, collectively called the Whistling Ridge Energy Project, of up to 50 1.2- to 2.5-MW wind turbines with a total capacity of 75 MW of electricity. The project would be located on a 1,152-acre site in unincorporated Skamania County owned by SDS Co, LLC and Broughton Lumber Company, on the forested ridges of Saddleback Mountain. Each turbine would be up to approximately 426 feet tall to the tops of the blades extended over the tower of the wind turbine. In addition to the turbines, the planned facility would include: electrical transformers, 34.5 kilovolt collector lines and systems (primarily underground), permanent meteorological towers, an Operations and Maintenance facility (including bathrooms and kitchen), a new well for potable water, an on-site septic system, a substation located adjacent to BPA’s existing North Bonneville to Midway 230-kv transmission line, and approximately 2.4 miles of newly-constructed and 7.2 miles of improved roads to provide access to the wind turbine locations during construction and for Operations and Maintenance.

The proposal states that several wind turbines will be placed in a Residential 10 (R10) zoning designation on the project site. While researching the parcels using the County’s Geographic Information System (GIS), legal descriptions and official zoning maps, no R10 zoning designation was found within the project site. The proposal states that roughly 400 acres of the project site is located within FOR/AG 20 zoning and Residential 10 zoning designations. However, Community Development staff research of the County’s GIS and assessor maps show that approximately 1,036 acres of the project site is unzoned, and approximately 127 acres of the project site is zoned FOR/AG 20. County GIS and assessor maps show the project area to be approximately 1,163 acres, however, this is just an approximation based on legal descriptions since no boundary survey was conducted. This information does not affect the consistency review of the project, rather it is a clarification of the project based on County’s consistency review.

The proposal further includes improvements to roads and intersections within the National Scenic Area in order to provide access to the project site. The roadways
affected include Cook Underwood Road, Kollock-Knapp Road, Scoggins Road and private road logging CG2930. Improvements to the county roadways and the private logging road would be necessary to support the long and heavy loads that would be required for the delivery of the wind energy components from SR 14 to the proposed project site. These improvements may include 1) Rebuilding large sections of the existing roadway network, 2) Widening certain sections of the existing roadway network, 3) Flattening and/or rebuilding existing roadway topography both horizontally and vertically, and 4) Placing asphalt in select areas for equipment access.

II. GENERAL INFORMATION

Owner(s): SDS Lumber Co  Broughton Lumber Co
            PO Box 266  92 Office Road
            Bingen, WA  Underwood, WA
            98605  98651

Applicant(s)/Applicant(s) Representative:
            Jason Spadaro, President, SDS Lumber Co
            and Whistling Ridge Energy, LLC
            PO Box 266
            Bingen, WA 98605

Tax Parcel Number(s):
            03-10-00-0-0-0300-00 (portion)
            03-10-00-0-0-0400-00 (full)
            03-10-00-0-0-0800-00 (portion)
            03-10-00-0-0-1100-00 (portion)
            03-09-00-0-0-2990-00 (portion)

Location:
            Skamania County Road Right-of-Way
            The subject parcels are located in the eastern portion of Skamania T3N, R10E & T3N, R9E, W.M.

Zoning:
            127 acres of the proposed project area is zoned FA20. The remaining 1,036 acres is un-zoned.
            NSA: the roadways within the NSA are zoned General Management Area, Large-Scale Agriculture (Ag-1), Commercial Forest (F-1), Small Woodland (F-3), Residential, and Open Space (OS).

Comprehensive Plan Designation
            Conservancy (outside NSA)

Square Footage/Acreage:
            The entire project area is located outside of the NSA and is 1,152 acres (1,163 acres by County calculations), spanning portions of five parcels. Approximately 384 acres would be developed for the wind turbine foundations, connecting roadways, and overhead and underground transmission lines.

Proposed Use
            Semi-public utility facility
            Road Improvements (w/in NSA)

Number of Lots:
            The project area spans portions of five parcels.

Density:
            N/A
III. HISTORY/BACKGROUND:
Skamania County is one of ten counties in Washington State that is not required to fully plan under the Growth Management Act. The County is not required to establish zoning classifications on all the land within its jurisdiction.

The 2007 Comprehensive Plan applies to all unincorporated land within Skamania County. The National Scenic Area is a sub-area which uses the Columbia River Gorge Management Plan as its Comprehensive Plan. Not all of unincorporated Skamania County has a zoning classification. The critical area regulations only apply outside of the NSA. Within the NSA there is a comprehensive land use application that reviews projects for Scenic, Natural, Cultural, and Recreational resources. The project area is outside of the NSA. The only potential work to be conducted within the NSA is improvements to existing roads which is an allowable review use in the NSA Land Use classification.

SDS Co. LLC submitted their application for the Whistling Ridge Energy Project on March 10, 2009. Skamania County Community Development Department is providing EFSEC with a consistency review of all county regulations that apply to the project.

IV. SEPA THRESHOLD DETERMINATION:
EFSEC issued a scoping notice on April 6, 2009 to begin the EIS review process. A revised notice was issued April 21, 2009.

V. PUBLIC HEARING NOTICE:
EFSEC published all required notices.

VI. NATURAL ENVIRONMENT
A. Topography:
The resource maps indicate that the subject parcels within the project area, have slopes ranging from zero percent to over 40%. Under Skamania County’s Critical Areas Ordinance (Title 21A), the subject parcels are located in a Class II Landslide Hazard Area. As such, this requires a geotechnical assessment report be completed for the proposed project. A geotechnical assessment report is prepared by a Washington state licensed hydrologist or geologist and requires the following, at minimum:
a. a description of the topography, surface and subsurface hydrology, soils geology, and vegetation of the site;
b. an evaluation of the analysis area's inherent erosion hazards;
c. a site plan of the area delineating all areas of the site subject to erosion hazard; and
d. proposed mitigation measures to be implemented by the applicant, including, but not limited to, minimizing site disturbance or grading, implementing erosion control measures, such as the retention of existing vegetation and controlling surface water drainage through stormwater retention and detention systems.

B. Soils:
According to the Natural Resources Conservation Service (NRCS) Soil Survey of Skamania County, the soil types of the parcels are: McElroy gravelly loam (types 66, 67, 68), Timberhead gravelly loam (types 135, 136), Underwood loam (type 144). Each of these soils has a T Factor of 5. Under Skamania County's Critical Areas Ordinance, Title 21A, the subject parcels are located in a Class I Erosion Hazard Area.

C. Surface Water:
Within the proposed project area there is: One (1) Class 4N stream; 19 Class 5N streams; and five (5) unclassified streams.

The proposal states that one stream, a Class V, will be crossed. This stream is located outside of the project area (see review in NSA Title 22) within the National Scenic Area boundary. The proposal states that no new construction will occur within any stream or its associated buffer that is located within the project area (outside of the NSA).

D. Vegetation:
The project area is covered by second and third growth commercial timber stands.

E. Wildlife:
The entire project area is within Elk winter range habitat. No other habitat was found on resource maps.

F. Sensitive Areas:
No Sensitive Areas were found on the Resource maps within the proposed project area. No known cultural or archaeological resources were found within the project area.

VII. NEIGHBORHOOD CHARACTERISTICS
The Comprehensive Plan designation of this project area is Conservancy. Some of the surrounding area is Rural Lands II, with the majority being Conservancy.

The southern project boundary line (including the southeast project line) borders the Columbia River Gorge National Scenic Area.
VIII. TRANSPORATION PLANS
Access of the proposed site would be provided from State Route 14 to Cook-
Underwood Road, Kollack-Knapp Road, Scoggins Road and a private logging road
listed as CG2930, located on SDS Lumber Company and Broughton Lumber
Company property. These access roads are located within the National Scenic Area.

IX. UTILITIES
A. Stormwater:
Discharge of stormwater runoff would be regulated by EFSEC based on the
Department of Ecology’s stormwater pollution control program. The proposal
indicates mitigation measures by Best Management Practices and by
implementing a Stormwater Pollution Prevention Plan (SWPPP) during and after
construction. The final design would conform to the applicable Ecology
Stormwater Management Manual in effect at the time or as instructed by EFSEC.

B. Wastewater Disposal:
The Applicant is required to apply for an On-Site Septic System permit as the
Operations and Maintenance Building will include bathroom and kitchen facilities.
Prior to issuance of any building permit, the applicant is required to have an
approved On-Site Septic System Design.

C. Potable Water:
Prior to the issuance of a building permit for the proposed Operations
and Maintenance Building, the applicant is required to have an approved Water
Availability Verification Evaluation (WAVE).

X. COMPREHENSIVE PLAN
The following Goals and Policies of the Skamania County Comprehensive Plan are
applicable to the proposed project.

Chapter 2: Land Use Element
Goals and Policies
Conservancy Designation

Goal LU.1: To integrate long-range considerations (comprehensive planning) into the
determinations of short-term action (individual development applications).

Policy LU.1.2: The plan is created on the premise that the land use areas designated
are each best suited for the uses proposed therein. However, it is not the intention
of this plan to foreclose on future opportunities that may be made possibly by
technical innovations, new ideas and changing attitudes. Therefore, other uses that
are similar to the uses listed here should be allowable uses, review uses or
conditional uses, only if the use is specifically listed in the official controls of
Skamania County for that particular land use designation.

Finding:
The project area lies within the Conservancy Comprehensive Plan Designation.
Within the conservation designation, public facilities and utilities, and utility
substations are allowed.
Conclusion:
The project is considered a semi-public utility facility and would therefore be consistent with the Conservancy Designation.

Goal LU.3: To coordinate public and private interests in land development.

Policy LU.3.3: Encourage industry that would have minimal adverse environmental or aesthetic effects.

Finding:
The project area is located outside of the Columbia River Gorge National Scenic Area boundary. The turbines would be painted gray to minimize aesthetic effects. The proposed project would be located within an area where roadways and high voltage regional transmission lines already exist, which would minimize the need for new disturbances.

Conclusion:
The project is consist with this goal and policy.

Goal LU.4: To promote interagency cooperation and effective planning and scheduling of improvements and activities so as to avoid conflicts, duplication and waste.

Policy LU.4.3: Land use patterns, which minimize the cost of providing adequate levels of public services and infrastructure, should be encouraged.

Finding:
High-voltage regional transmission lines, owned and operated by Bonneville Power Administration (BPA) are located on the project site. Access roadways already exist. The project uses existing patterns in Land Use which helps to minimize the public costs of providing services and new infrastructure.

Conclusion:
The project is consistent with this goal and policy.

Goal LU.5: To promote improvements which make our communities more livable, healthy, safe and efficient.

Policy LU.5.5: Promote compatibility of industry with the surrounding area or community by fostering good quality site planning, landscaping, architectural design, and a high level of environmental standards.

Policy LU.5.7: Adequate on-site wells and septic systems should be properly installed, monitored and maintained in accordance with local and state health departments.

Finding:
The proposed project is located in the Conservancy Designation, which allows for public utility facilities and utility stations. The surrounding areas are Conservancy Designation, as well as Rural Lands II Designation, which also allows for utility facilities and utility substations. The project site has been previously logged by forestry activities and the proposal would allow the forestry activities to continue.
High-voltage transmission lines, cell towers and rock quarries currently exist in the area, so the project would be compatible with these uses.

The proposed Operations and Maintenance Building would include bathroom and kitchen facilities and would therefore be required to have an approved on-site septic system as well as an adequate potable water supply. This would be a condition of approval.

**Conclusion:**
The project is consistent with the goals and policies. A valid OSS and proof of potable water should be a condition of approval.

*Chapter 3: Environmental Element*  
*Goals and Policies*

**Goal E.1:** To ensure the proper management of the natural environment to protect critical areas and conserve land, air, water and energy resources.

**Policy E.1.4:** Implement and preserve critical area buffers based on Best Available Science adjacent to critical areas to adequately protect such areas from development and land use impacts.

**Finding:**
Several streams exist on the proposed project site, with buffers ranging from 25' to 50', which must be maintained at all times unless exemptions are met or variances are granted.

**Conclusion:**
This proposal is consistent with the goals and policies.

**Goal E.3:** To minimize the loss of life and property from landslides, seismic, volcanic or other naturally occurring events, and minimize or eliminate land use impacts on geologically hazardous areas.

**Policy E.3.4:** Require geotechnical studies to determine construction methods and technologies necessary to further public safety in geologically hazardous areas. The development design and construction technology used shall be appropriate to the soil limitations on the particular site.

**Finding:**
The project should require a geotechnical assessment report and soil borings to be conducted on-site. The report should be reviewed and accepted by Skamania County prior to issuing any building permits. Any and all setbacks determined within the report must be followed.

**Conclusion:**
The project is consistent with these goals and policies.

*Chapter 4: Transportation Element*
Goal T.1: Transportation – Encourage an efficient multi-modal transportation network that is based on regional priorities and coordinated with county and city comprehensive plans.

Goal T.3: Public Facilities and Services – Ensure that those public facilities and services necessary to support development should be adequate to serve the development at the time the development is available for occupancy and use without decreasing current service levels below locally established minimum standards.

Finding:
All roadways that will be used for this proposal are existing and some improvement will be necessary for the transportation of the equipment and construction materials. Some intersection improvements are needed to allow safe turning of construction and equipment delivery vehicles. These improvements, as well as the added traffic, would not degrade the existing levels of service at nearby intersections below minimum standards. The applicant should consult with the Skamania County Public Works Department regarding the sufficiency of roads. Turbine equipment would likely be transported to either the Port of Longview or the Port of Vancouver, and much of it transported by barge up the Columbia River to the Applicant’s existing barge and dock facilities in Bingen, Washington. If rail is used, it will be by existing rail lines.

Conclusion:
This proposal is consist with these goals and policies. The road improvements will enhance the level of service on these roads and benefit the community.

Chapter 5: Archaeology and Historic Preservation Element

Goal AHP.1: Identify and encourage the preservation of lands, sites, and structures that have historical or archaeological significance:

Policy AHP.1.3: Coordinate county inventory efforts with Native American groups and governmental efforts.

Finding:
Research conducted by Skamania County Community Development found no archaeological or historical resources located on the project area. CH2M HILL conducted an intensive cultural resource inventory survey of the proposed area of potential effect in August 2003. No evidence of prehistoric activity was observed and no archaeological sites or historic properties were identified, although two historic archaeological isolates were found and documented, consisting of piled basalt cobbles and scatter of historic debris previously disturbed by power line construction and logging. No known archaeological or cultural resources were found on the Washington State Department of Archaeological and Historic Preservation (DAHP) resource maps which staff used to research the project area.

Further, if the project would have applied for a Conditional Use permit, the application would have been sent to various state agencies, federal agencies, and Native American Governments, allowing the opportunity to comment on the project. EFSEC should consult with these groups during the process.
Conclusion:
This project is consistent with these goals and policies.

Goal AHP.3: Protect historic, archaeological, and cultural resources through a comprehensive planning approach.

Finding:
Research conducted by Skamania County Community Development found no archaeological or historical resources located on the project area. CH2M HILL conducted an intensive cultural resource inventory survey of the proposed area of potential effect in August 2003. No evidence of prehistoric activity was observed and no archaeological sites or historic properties were identified, although two historic archaeological isolates were found and documented, consisting of piled basalt cobbles and scatter of historic debris previously disturbed by power line construction and logging.

Conclusion:
This project is consistent with these goals and policies.

XI. STATUTES/CODES:

Skamania County Code Title 21 – Zoning

Chapter 21.64 – Unmapped Classification (UNM)

21.64.020 – Allowable Uses
In the areas classified as Unmapped, all uses which have not been declared a nuisance by statute, resolution, ordinance, or court of jurisdiction are allowable. The standards, provisions, and conditions of this title shall not apply to unmapped areas.

Finding:
1,036 acres of this project is unzoned and therefore there are no restricted uses. Utility facilities and utility substations have not been declared a nuisance by a known Washington State Court or by local ordinance or resolution or by any known state or federal statutes.

Conclusion:
The project is consistent with the zoning designation of UNM.

Chapter 21.56 – Resource Production Zone Classification (FOR/AG 10 & 20)

21.56.030 – Conditional Uses
(C) Semi-public facilities and utilities

Finding:
Approximately 127 acres of this project is located within the FOR/AG 20 zoning classification. The "A" string of the project within this zoning classification. The "A" string includes seven turbines. All other proposed turbines are outside of the zoned area. Semi-public facilities and utilities are a conditional use within this zoning designation. The applicant would need to submit a conditional use application for review by the Hearing Examiner for
approval of this project if the County was conducting the project review. Conditional use permits are reviewed and issued by the County Hearing Examiner.

21.16.070 - Hearing Examiner - Duties and Responsibilities

The Hearing Examiner shall hear and decide:

A. Applications for conditional uses. Conditional uses are those uses, which may or may not be compatible with permitted uses in a specific zoning designation. If the Hearing Examiner determines the use is not compatible with permitted or existing uses in the specific area of the proposed use then the proposed use shall be denied. Alternatively, if the Hearing Examiner determines that the proposed use is compatible with permitted and existing uses in the specific area of the proposed use then the proposed use shall then the proposed use may be approved or approved with conditions to make it make it compatible with the area.

1. In determining whether the use is compatible with the area, the proposed use shall:

   a. Be either compatible with other uses in the surrounding area or is no more incompatible than are other outright permitted uses in the applicable zoning district;

Finding:
The proposal is to install up to 50 wind turbines on a parcel of land in unincorporated Skamania County, 1,036 acres are unzoned, and 127 acres are zoned FOR/AG 20. The entire proposal is located within the Conservancy Comprehensive Plan Designation.

Unzoned areas of Skamania County and the Conservancy Comprehensive Plan Designation allow for public utility facilities and utility substations. The FOR/AG 20 zoning district lists semi-public utility facilities and utility substations as a conditional use and allows public facilities outright with no additional zoning review being required.

The surrounding areas are located within the Conservancy Designation, as well as the Rural Lands II Designation, both of which allow public utility facilities and utility substations. The property is currently uses for commercial forestry activities, and these activities will be allowed to continue once the turbines are constructed. Cell towers, high-voltage transmission lines and rock quarries exist in the area. There is a small portion of the project site that abuts Residential 10 (R10) zoning, which also lists semi-public utilities as conditional use.

Conclusion:
The proposal is compatible with other uses within the area, both within the Comprehensive plan designation and the zoning designation.

   b. Not materially endanger the health, safety, and welfare of the surrounding community to an extent greater than that associated with other permitted uses in the applicable zoning district.

Finding:
The subject parcel is located in a geological hazard area due to the slope and soil type and requires a geotechnical assessment report.
The applicant is required to show proof of potable water and obtain an on-site septic system permit from the Skamania County Community Development Department through the building permit process. The proposal includes bathroom and kitchen facilities located in the Operation and Maintenance Building.

EFSEC has required an EIS to be prepared and will ultimately decide what conditions of approval would be necessary for the project to be found to not materially endanger the health, safety and welfare of the surrounding community. By obtaining the water, septic and building permits, conducting the geotechnical analysis and best management practices during construction, the project could be found consistent with this provision.

**Conclusion:**
The proposal will not materially endanger the health, safety, and welfare of the surrounding community.

1. **c. Not cause the pedestrian and vehicular traffic associated with the use to conflict with existing and anticipated traffic in the neighborhood to an extent greater than that associated with other permitted uses in the applicable zoning district.**

**Finding:**
Access of the proposed site would be provided from State Route 14 to Cook-Underwood Road, Kollack-Knapp Road, Scoggins Road and a private logging road listed as CG2930, located on SDS Lumber Company and Broughton Lumber Company property.

All roadways that will be used for this proposal are existing and some improvement will be necessary for the transportation of the equipment and construction materials. Some intersection improvements are needed to allow safe turning of construction and equipment delivery vehicles. These improvements, as well as the added traffic, would not degrade the existing levels of service at nearby intersections below minimum standards. The applicant will consult with the Skamania County Public Works Department regarding the sufficiency of roads and road upgrade requirement. Other permitted uses include: single family residences in conjunction with forest or farm management, recreational facilities, semi-public facilities and utilities, saw mills, shake and shingle mills, chippers, pole and log yards, geothermal energy facilities, aircraft landing fields, cluster developments, child mini day care centers, and child day care centers.

**Conclusion:**
The proposal will not cause a conflict with existing pedestrian and vehicular traffic.

2. **d. Be supported by adequate service facilities and would not adversely affect public services to the surrounding area.**

**Finding:**
The proposal states that an Engineering, Procurement, and Construction (EPC) contractor will prepare a safety plan that would apply to all personnel working on-site. The plan would ensure compliance will all laws, ordinances, regulations
and standards concerning health and safety. An Environmental Compliance Program would cover avoidance of sensitive areas during construction, waste handling and storage, stormwater management, spill prevention and control, and other components required by State and County regulations. An Emergency Response Plan would be established to ensure employee safety from the following: medical emergency, major power loss, fire, extreme weather, earthquake, volcano, and bomb threat. This plan would be established prior to construction.

**Condition:**
All safety plans and programs are required to be in place prior to construction. These plans and programs should be included as a conditional of approval.

  e. *Not hinder or discourage the development of permitted uses on neighboring properties in the applicable zoning district as a result of the location, size, or height of the buildings, structures, walls, or required fences or screening vegetation to a greater extent than other permitted uses in the applicable zoning district.*

**Finding:**
The proposal is to install up to 50 wind turbine structures on a project site spanning portions of five parcels. This use is classified as a semi-public utility facility within the FOR/AG 20 zoning designation.

Other uses in the FOR/AG 20 zoning designation include, among others: forestry practices and associated management activities of forest crop, commercial and domestic agriculture, water resource management facilities, log sorting and storage areas, etc.

Surrounding zoning includes FOR/AG 20, as well as R10 (Residential 10) outside of the NSA. To the south of the project area, inside the NSA, the surrounding area is zoned Large Scale Agriculture, Commercial Forest, Small Woodland and Open Space. Current uses surrounding the project site include commercial forestry uses, agriculture including pear and apple orchards, and three small, unincorporated residential communities and other agriculture related dwellings.

**Conclusion:**
The proposal is compatible with other uses in the region and will not effect the allowed uses on those parcels. The proposal states commercial forestry activities will likely continue on the project site parcels as well.

  f. *Not be in conflict with the goals and policies expressed in the current version of the County’s comprehensive plan.*

**Finding:**
As discussed above, the proposal is consistent with the Skamania County Comprehensive Plan.

  2. *Criteria for determining conditions to be imposed on conditional uses shall be based on the health, safety, and general welfare of the public, any environmental standards in force in Skamania County,*
other applicable provisions set forth in this Title and shall be subject to conditions which may include, but are not limited to the following:

a. Limiting the manner in which the use is conducted including restricting the time an activity may take place, and restraints to minimize such environmental effects as noise, vibration, air pollution, glare, and odor.

Finding:
The EIS and EFSEC will determine what conditions, if any, are required to be implemented for this project.

b. Establishing a special yard, open space, lot area or lot dimensions.

Finding:
Not applicable

c. Limiting the height, size, or location of a building or other structure.

Finding:
127 acres of this project site, which includes seven proposed turbines, is located within FOR/AG 20 zoning designation. Under the current FOR/AG 20 zoning designation, the required front yard setback is 35-feet from the centerline of the private road or 20-feet from the front property line with the front defined as the line which parallels a public road right-of-way or a private road easement, or that line where a road, driveway, or access panhandle enters a lot. The required rear setback under the current regulations is 20-feet from the rear lot line with the rear defined as the lot line which is opposite and farthest away from the front lot line.

The remainder of this parcel, 1,036 acres, is unzoned and therefore has setbacks as determined by the Building code list from Title 15. Building Code setback requirements for un-zoned lots 12,500 square feet or larger is:
Front Yard: No building or accessory building shall be constructed closer than 45 feet from the centerline of the public road right-of-way or 35 feet from the centerline of the private road (note including private driveways), or road or 15 feet from the front property line, whichever is greater;
Side Yard: On each side of the building or accessory building a side yard shall be provided for not less than 5 feet; and
Rear Yard: A rear yard shall be provided of not less than 15 feet, including accessory buildings.

Conclusion:
Under the current regulations, the proposed location meets the minimum requirements. However, EFSEC may require additional setbacks or micro-siting of turbines.

d. Designating the size, number, location, and nature of vehicle access points.
Finding:
No new roads are proposed at this time. The EIS traffic studies and road design plan will determine any requirements for vehicle access points.

   e. Increasing the amount of street dedication, roadway width, or improvements within the street right-of-way.

Finding:
The EIS traffic studies and road design plans will determine the necessary road improvements. No new roads are proposed at this time.

   f. Limiting or otherwise designating the number, size, location, height, and lighting of signs.

Finding:
Non-applicable

   g. Limiting the location and intensity of outdoor lighting and requiring it to be shielded.

Finding:
Lighting of turbine strings will need to meet Federal Aviation Administration (FAA) requirements. Lighting on buildings are requested to be hooded and shielded. This is a request and not currently a requirement in the County zoning code.

   h. Requiring berming, screening, landscaping, or another facility to protect adjacent or nearby properties and designating standards for its installation and maintenance.

Finding:
The residences closest to the project site are located approximately 0.48 mile and 0.8 mile from proposed turbine locations. A new homesite location has been applied for, and would be approximately 2,000 feet (0.38 Mile) from the south property line. The unincorporated community of Willard is located approximately 2.25 miles northwest of the project site. The unincorporated community of Mill A is also located near the project site, approximately 1.5 miles west of the site. The homes near the project site are rural, primarily single family, between 30 and 50 years old, and low- to medium-density.

Conclusion:
In order to protect adjacent and nearby properties, the applicant should only excavate the minimum needed to install the wind turbines and accessory structures, and the Operations and Maintenance facility, maintain existing trees, and re-vegetate all undeveloped disturbed areas with native trees and shrubs along the west and south lot lines. However, since this land is being used for Commercial Forestry, the removal of timber in conjunction with this operation should not be restricted.

   i. Designating the height, location, and materials for a fence.

Finding:
EFSEC will determine if any fencing is required for safety and/or aesthetic
reasons.

j. Protecting and preserving existing trees, vegetation, water resources, wildlife habitat, or other significant natural, historic, or cultural resources.

Finding:
The proposed project is located within a Class II Landslide Hazard Area and a Class I Erosion Hazard Area due to the soil type and requires a geotechnical assessment report. The entire project site is also located within elk winter range habitat. Several streams exist on site, which would require buffers ranging between 25' to 50'. There are no current County requirements to preserve trees or vegetation outside of critical resource stream buffers. No cultural or historic resources found in database research.

Conclusion:
In order to prevent possible wind and water erosion, the applicant should use Best Management Practices during all phases of construction and replant all undeveloped disturbed areas with native vegetation. The project requires a geotechnical assessment report to address the landslide hazard on the property.

Skamania County Code Title 21A – Critical Areas

21A.04.010 - General Provisions

A. RELATIONSHIP TO SHORELINES MANAGEMENT MASTER PLAN AND SHORELINES MANAGEMENT ACT PERMITS ORDINANCE.

In event of any conflict between this Title and regulations contained in the Shorelines Ordinance, those regulations that provide greater protection of Critical Areas shall apply.

Finding:
There are several streams located on the subject parcel. The proposal is to erect up to 50 wind turbine structures. No stream located on-site is a Shoreline of Countywide or Statewide significance and therefore the Skamania County Shoreline Management Program does not apply.

Conclusion:
Skamania County Critical Areas Ordinance, Title 21A, provides the greatest protection to the critical areas and only applies outside of the National Scenic Area.

21A.04.030 - STREAMS, CREEKS AND RIVERS

(4) Buffer Widths

(b) ... undisturbed buffers shall be preserved around all regulated streams, creeks and rivers.

(c) The required width of undisturbed buffer areas shall depend upon the class of water represented by the stream, creek or river protected, the type or scale of use or development proposed by an applicant and the vegetative community adjacent to the water body.
(iv) For Class IV streams, creeks and rivers, the standard buffer zone width shall be 50 feet.  
(v) For Class V streams, creeks and rivers, the standard buffer zone width shall be 25 feet.

Finding:
The proposed project area includes several streams ranging from a 25’ to 50’ undisturbed buffer requirement. The proposal states that no new construction would occur within wetlands, streams, or associated buffers. The existing road improvements in these regulated fish and wildlife protection areas do not exceed the allowed expansion threshold (100% or less of the original footprint).

The only existing roadway to receive improvements crosses a Class V stream within the National Scenic Area. (See Title 22 below)

Conclusion:
Maintaining critical areas buffers should be a condition of approval.

21A.05.050 – Fences in Deer and Elk Winter Range
(A) New development permits issued by the County shall include a requirement that, in deer and elk winter range, construction of new and replacement fences shall be subject to the following:
1. New fences in deer and elk winter range shall be allowed only when necessary to control livestock or pets or to exclude wildlife from specified areas, such as gardens or orchards. Fenced areas shall be the minimum necessary to meet the needs of the project applicant.
2. New and replacement fences in winter range shall comply with the following, unless the applicant demonstrates the need for an alternative design:
   a. The top wire shall not be more than 42 inches high to make it easier for deer to jump over the fence.
   b. The distance between the top two wires shall be at least 10 inches to make it easier for deer and to free themselves if they become entangled.
   c. The bottom wire shall be at least 16 inches above the ground to allow fawns to crawl under the fence. It should consist of smooth wire because barbs often injure animals as they crawl under the fence.
   d. Stays or braces placed between strands of wire shall be positioned between fence posts where deer are most likely to cross. Stays create a more rigid fence, which allows deer a better chance to wiggle free if their hind legs become caught between the top two wires.
3. Woven wire fences may be authorized only when a project applicant clearly demonstrates that such a fence is required to meet his or her specific needs, such as controlling hogs and sheep.

Finding:
EFSEC will determine if any fencing is required for safety and/or aesthetic reasons.
Conclusion:
If EFSEC requires fencing, a condition of approval should be to follow the above guidelines for fencing within deer and elk winter range.

21A.06 Geologically Hazardous Areas
21A.06.010 Erosion Hazard Areas

A. Class I Erosion Hazard Areas:
Class I Erosion Hazard Areas (EHAs) area areas that are subject to severe development constraints due to a site’s susceptibility to erosion from wind and/or water.

Class I EHAs are identified in the Soil Survey of Skamania County Areas, Washington, prepared by the United States Department of Agriculture, Soil Conservation Service, as having an index of greater than or equal to 3.75

21A.06.020 Landslide Hazard Areas

A. Class II Landslide Hazard Areas (LHAs) are areas with slopes 20% and 30% that are underlain by soils that consist largely of silt, clay or bedrock, and all areas with slopes greater than 30%.

Class II LHAs shall be identified using the Soil Survey of Skamania County Areas, Washington, prepared by the United States Department of Agriculture, Soil Conservation Service. Department personnel shall make a preliminary determination of percentage of slope. The applicant shall verify soil type and precise percentage of slope.

Finding:
The proposed project site is located within a Class I Erosion Hazard Area and a Class II Landslide Hazard Area under Skamania County Critical Areas Ordinance Title 21A. The resource maps indicate that the subject parcels have slopes ranging from zero percent to over 40%. As such, this requires a geotechnical assessment report be completed for the proposed project. A geotechnical assessment report is prepared by a Washington state licensed hydrologist or geologist and requires the following, at minimum:

a. a description of the topography, surface and subsurface hydrology, soils geology, and vegetation of the site;

b. an evaluation of the analysis area’s inherent erosion hazards;

c. a site plan of the area delineating all areas of the site subject to erosion hazard; and

d. proposed mitigation measures to be implemented by the applicant, including, but not limited to, minimizing site disturbance or grading, implementing erosion control measures, such as the retention of existing vegetation and controlling surface water drainage through stormwater retention and detention systems.
Conclusion:
The proposal discusses submitting a geotechnical assessment report and performing soil borings on site. This report must be reviewed and approved by Skamania County and will be a condition of approval.

Skamania County Code Title 22 – Columbia River Gorge National Scenic Area

ADMINISTRATION
SCC Section 22.06.020, states that "No building, structure or parcel of land shall be used, and no building or structure shall be hereafter erected, altered or enlarged, including those proposed by local, state or federal agencies, in that portion of the County lying within the Columbia River Gorge National Scenic Area in any manner that is inconsistent with the provisions of this Title."

ZONING
The subject roadways are in the General Management Area (GMA), on lands zoned Large-Scale Agriculture (Ag-1), Commercial Forest (F-1), Small Woodland (F-3), Residential, and Open Space (OS). The following sections of Skamania County Code Title 22 are what the proposed road modifications would be reviewed under within each land use designation:

SCC Section 22.14.010(C) Large-Scale Agricultural (Ag-1) Zone Review Uses:
   (h) Construction, reconstruction or modifications of roads, not in conjunction with agriculture or with forest use or forest practices.

SCC Section 22.14.030(E) Commercial Forest (F-1) Zone Review Uses:
   (h) Construction, reconstruction or modifications of roads, not in conjunction with agriculture or with forest use or forest practices.

SCC Section 22.14.050(E) Small Woodland (F-3) Zone Review Uses:
   (h) Construction, reconstruction or modifications of roads, not in conjunction with agriculture or with forest use or forest practices.

SCC Section 22.14.060(D) Residential Zone Review Uses:
   (c) Construction, reconstruction or modifications of roads.

SCC Section 22.14.110(C) Open Space (OS) Zone Review Uses:
   (c) Repair, maintenance, operation and improvement of existing structures, trails, roads, railroads, utility facilities and hydroelectric facilities.

Finding:
The proposed Whistling Ridge Energy Project will require the improvement of roads and intersections within the National Scenic Area in order to provide access to a semi public utility facility. The roads that would require improvement are within five different land use designations within the General Management Area of the National Scenic Area. Each of these five designations allows for the modification or improvement of existing road as a review use. Prior to implementation of any road improvements a National Scenic Area Land Use Application should be submitted to the Skamania County Community Development Department. It would be reviewed with the Columbia River Gorge
National Scenic Area Ordinance Title 22 that is in effect at the time of the application.

SCENIC RESOURCE PROTECTION

**TOPOGRAPHIC VISIBILITY**
The road improvement project within the National Scenic Area is topographically visible from the following key viewing areas from the approximate distances:

</table>
The improvements to the existing roads within the National Scenic Area will require review for consistency with the provisions for the protection of scenic resources. Projects within the National Scenic Area are reviewed to ensure that the development will be visually subordinate as seen from twenty-two (22) key viewing areas within the National Scenic Area. **The criteria for Scenic Resource Protection (in Chapter 22.18) cannot be used as grounds to deny a proposed use, but may affect the siting, location, size and other design features of proposed developments (see Section 22.18.010(A)).**

**Finding:**
Prior to implementation of any road improvements a National Scenic Area Land Use Application should be submitted to the Skamania County Community Development Department. It would be reviewed with the Columbia River Gorge National Scenic Area Ordinance Title 22 that is in effect at the time of the application. Conditions may be applied to various elements of the proposed development to ensure they are visually subordinate to their setting as seen from key viewing areas.

**NATURAL RESOURCE PROTECTION**
The existing logging road CG2930 includes the crossing of one stream. This crossing will require road expansion. SCC Section 22.20.020(A)(2) allows for the modification, expansion, replacement or reconstruction of serviceable structures, if the actions would not:

- a. Increase the size of an existing structure by more than 100 percent,
- b. Result in a loss of wetlands acreage or functions, or cause a loss of water quality, natural drainage, and fish and wildlife habitat in streams, ponds, lakes and riparian areas, or
- c. Intrude further into a water resource zone. Structures shall be considered intruding further into a water resource zone if any portion of the modified, expanded, replaced, or reconstructed structure is located closer to the water resource than the existing structure.

In order to allow for the expansion of the crossing of the one seasonal stream, the project will be required to meet the Practicable Alternative Test found in SCC Section 22.20.010:

A) An alternative site for a proposed use shall be considered practicable if it is available and the proposed use can be undertaken on that site after taking into consideration cost, technology, logistics, and overall project purposes. A practicable alternative does not exist if a project applicant satisfactorily demonstrates all of the following:

1) The basic purpose of the use cannot be reasonably accomplished using one or more other sites in the vicinity that would avoid or result in less adverse effects on wetlands, ponds, lakes, riparian areas, wildlife or plant areas and/ or sites;

2) The basic purpose of the use cannot be reasonably accomplished by reducing its proposed size, scope, configuration, or density, or by changing the design of the use in a way that would result in less adverse effects on wetlands, ponds, lakes, riparian areas, wildlife or plant areas and/ or sites; and;

3) Reasonable attempts were made to remove or accommodate constraints that caused a project applicant to reject alternatives
to the proposed use. Such constraints include inadequate infrastructure, parcel size, and land use designations. If a land use designation or recreation intensity class is a constraint, an applicant must request a Management Plan amendment to demonstrate that practicable alternatives do not exist.

If these conditions are met, the stream crossing expansion will require best management practices, must not alter or destroy stream function and water quality, and the applicant will need to rehabilitate the area to the maximum extent practicable.

**Finding:**
Prior to implementation of any road improvements a National Scenic Area Land Use Application should be submitted to the Skamania County Community Development Department. It would be reviewed with the Columbia River Gorge National Scenic Area Ordinance Title 22 that is in effect at the time of the application. Conditions may be applied to various elements of the proposed development to ensure that the project meets the above-mentioned requirement.

The following sensitive wildlife areas or sites may occur within 1,000 feet of the project:
Mule, Blacktail Deer and Elk habitat, Cliffs/Bluffs habitat, Osprey nest site, Ringneck snake, Larch Mountain Salamander Hood Area and sites, Western Gray Squirrel nest sites, California Mountain Kingsnake, and Waterfowl Wintering Area.

SCC Section 22.20.030 requires that all projects within the National Scenic Area that are located within 1,000 feet of any known wildlife area or sites require review for wildlife habitat protection. The project is located within 1,000 feet of known wildlife areas and sites within the National Scenic Area. Skamania County Community Development would work with the Washington State Department of Fish and Wildlife (WDFW) to determine if the applicant would be required to hire a wildlife biologist to prepare a Wildlife Management Plan.

**Finding:**
Prior to implementation of any road improvements a National Scenic Area Land Use Application should be submitted to the Skamania County Community Development Department. It would be reviewed with the Columbia River Gorge National Scenic Area Ordinance Title 22 that is in effect at the time of the application. The applicant may be required to hire a wildlife biologist in order to determine the impact the proposed road improvements of the project would have on wildlife areas and sites and how those impacts could be mitigated. Mitigation measures would be included as conditions of approval.

The following sensitive plant areas or sites may occur within 1,000 feet of the project:
Oregon White Oak/ Idaho Fescue, Douglas fir / Common Snowberry – Oceanspray, Diffuse Stickseed.

SCC Section 22.20.040 requires that all projects within the National Scenic Area that are located within 1,000 feet of any known sensitive plants require review.
for sensitive plant protection. The project is located within 1,000 feet of known sensitive plants within the National Scenic Area. Skamania County Community Development would work with the Washington Natural Heritage Program (WNHP) to determine if the applicant would be required to hire a person with recognized expertise in botany or plant ecology to conduct a field survey. If this is required, buffers or protection and rehabilitation plans may be required.

**Finding:**
Prior to implementation of any road improvements a National Scenic Area Land Use Application should be submitted to the Skamania County Community Development Department. It would be reviewed with the Columbia River Gorge National Scenic Area Ordinance Title 22 that is in effect at the time of the application. The applicant may be required to hire a person with recognized expertise in botany or plant ecology to conduct a field survey. If this is required, buffers or protection and rehabilitation plans may be required. Mitigation measures would be included as conditions of approval.

**CULTURAL RESOURCE PROTECTION**
Upon the submittal of a National Scenic Area Land Use Application the proposed road improvement project would be reviewed in accordance with SCC Chapter 22.22, Cultural Resource Protection. The application materials would be forwarded to Marge Dryden, Heritage Resources Program Manager for the Columbia River Gorge National Scenic Area. Ms. Dryden will determine if the proposed project requires Reconnaissance and Historic Survey reports. The proposed road improvement project would be considered a large-scale use, as SCC Section 22.22.010(E)(1)(e)(ii) includes public transportation facilities as a large-scale use. The applicant will be responsible for hiring a qualified professional to conduct a Reconnaissance Survey and prepare a report on their findings.

**Finding:**
Prior to implementation of any road improvements a National Scenic Area Land Use Application should be submitted to the Skamania County Community Development Department. It would be reviewed with the Columbia River Gorge National Scenic Area Ordinance Title 22 that is in effect at the time of the application. The applicant will be responsible for hiring a qualified professional to conduct a Reconnaissance Survey and prepare a report on their findings. Sections 22.22.060 Cultural Resources Discovered After Construction Begins and 22.22.070 Discovery of Human Remains as conditions of approval. These conditions will act as an Inadvertent Discovery Plan.

**RECREATIONAL RESOURCE PROTECTION**
SCC Section 22.24.010 Applicability of Chapter – Maps.
Proposed resource-based recreation facilities or uses shall be consistent with recreation intensity classes as set out on the Recreation Intensity Class maps adopted by the Columbia River Gorge National Scenic Area.

**Skamania County Code Title 24 – Clearing & Grading**

24.02.50 **Applicability**
Unless exempted under SCC Section 24.02.060, no person shall perform any grading activity without having first obtained a permit from the Department. Exemption from the permit process shall not relieve any person the requirement
for installation of appropriate erosion control measures for their project. No
permit or exemption granted pursuant to this title shall remove an applicant's
obligation to comply in all respects with the applicable provisions of any other
federal, state, or local law or regulation.

24.02.060 Exemptions
The following activities are exempt from the permit requirements of this title.
Materials from exempted excavations may require a separate permit for
placement as fill.
A. Mining, quarrying, excavating, processing, or stockpiling activities of rock,
sand, gravel, or clay if such operations are authorized by a valid Department
of Natural Resources Surface Mine Reclamation Permit or Skamania County
Conditional Use Permit or other provision of Skamania County Code.
B. All State Department of Natural Resources regulated Class I, II, III, or IV
special forest practice activity conducted in accordance with Chapter 76.09
RCW and WAC Title 222.
C. Grading, clearing, filling or excavation of less than 500 cubic yards, only if
located outside Critical Areas (SCC Title 21A) and regulated Shorelines (SCC
Title 20).
D. Emergency actions which must be undertaken immediately or for which there
is insufficient time for full compliance with this title in the event that:
1. There is an imminent threat to public health or safety.
2. There is imminent danger to public or private property;
3. There is an imminent threat of serious environmental degradation;
   a. A person or agency determines that the need to take
      emergency action is so urgent that there is not sufficient time
      for review by the Department; such emergency action may be
      taken immediately. Any person or agency undertaking such
      action shall notify the Department within one working day
      following the commencement of the emergency action.
      Following such notification the Department shall determine if
      the action taken was within the scope of the emergency
      actions allowed in this subsection. If the Department
determines that the action taken or part of the action taken is
beyond the scope of allowed emergency action, enforcement
action is authorized, as outlined in SCC Section 24.02.120.
   b. If the action taken qualifies as an emergency, and would have
      otherwise required a grading permit under this Title, then an
      application for a grading permit will be submitted with in 30
days following the emergency event. The application
      requirements, review, issuance, and inspections will be
      conditioned as outlined in this Title.
E. All exemptions as enumerated in the Critical Area and Shoreline Ordinances.
F. Nothing herein may interfere or overrule the Right to Farm Ordinance.
G. Nothing in this ordinance shall be retroactive and all current projects are
   hereby vested

Finding:
The proposal will include excavation work to install concrete foundations with a diameter
of up to approximately 60 feet for each wind turbine. The Collector System will disturb
an area approximately 30 feet in width, with 8.5 miles of underground collector cable
trenches proposed. Approximately 2.4 miles of new gravel access roads will be constructed as part of the proposal.

**Conclusion:**
As the volume and area of the clearing activities exceeds the exemption amount of volume and/or area, the applicant/property owner is required to obtain a Clearing and Grading Permit under SCC Section 24.02.050. EFSEC will make a determination on what conditions of approval are necessary.

**24.02.070 Application Requirements**
Unless exempted under SCC Section 24.02.060, all persons proposing to conduct grading and/or clearing activity within the jurisdictional boundaries of unincorporated Skamania County shall first apply for a grading permit. The applicant shall obtain a grading permit in conformance with this title prior to any grading activity.

A. The permit application shall at a minimum include the following:
   1. A completed application, signed by the property owner and the applicant, a vicinity map, environmental checklist (if required), and any relevant supplemental information required by the Director.
   2. Grading plans as described in SCC Section 24.02.080.
   3. A full identification and written description of the work to be covered by the permit for which the application is made.
   4. A timeline for completion of the project.
   5. Non-refundable application fee as determined by resolution of the Board of County Commissioners.

**Finding:**
The applicant/property owner does not meet the exempt criteria for a Clearing and grading permit and is therefore required to submit a Clearing and Grading permit application.

**Conclusion:**
The proposed project will require a Clear and Grading permit application which should be a condition of approval.

The proposal states that an Engineer licensed in the State of Washington will prepare detailed clearing and grading plans that will be submitted to EFSEC for review and approval prior to the start of construction. These plans will substantively comply with SCC Title 24 standards.

A. Granting of Permits
   1. After an application has been filed and reviewed the Director shall ascertain whether such proposed grading work complies with the provisions of this title. If the application and plans so comply, or if they are corrected or amended so as to comply, and the proposal is consistent with all other relevant county codes, the Director shall issue a grading permit.
   2. The applicant/property owner shall maintain the approved grading plans and permit available on the site, and provide an individual copy to any grading contractor who will be working at the site.
3. A grading permit shall be valid for a period of two years from the date of permit issuance, only for the grading work applied for. An extension may be granted for an additional 12 months for special circumstances. Request for extensions shall be submitted in writing to the Department prior to expiration of the current permit, setting forth the reasons and justification for the request. No permit may be extended more than once. Renewal of permits may be accomplished with existing plans and reports, if no changes are being made to the proposal, and no new significant issues are raised during the review.

Conclusion:
In order to be in compliance with this section of the Clearing and Grading Ordinance, a condition of approval shall be that the permit and grading plans are available on site and that the grading permit is valid for two years.

24.02.080 Grading Plan
An application for clearing and grading shall be accompanied by a grading plan. If the clearing and grading project involves engineered grading, then an engineered grading plan based on an engineering report or an engineering geology report shall be submitted with the application. Engineered grading plans shall be prepared and stamped by an engineering geologist, geotechnical engineer and/or civil engineer licensed to work in the State of Washington. Grading within a geological hazard critical area may require a geotechnical assessment report in compliance with the Critical Area Protection Ordinance (SCC Title 21A). A grading plan shall include:

A. An easily reproducible drawing at a scale of appropriate size to show location and details of all cuts and all fills including depth and finished slopes of all cuts and all fills.
B. A general vicinity map of the area and site plan of the project.
C. North arrow.
D. Dimensions and location of subject property boundary lines, location of the permit area boundary, existing and proposed roads, or driveways, easements, natural or man made bodies of water and drainages, critical areas, shorelines, and any existing or proposed structures, wells or septic systems on the site, and the distance between such features.
E. Bodies of water, critical areas, structures, wells, and septic systems on adjacent property and lying within 50 feet of the subject grading activity boundary that could be affected by the proposed grading operations.
F. Location and dimensions of buffer areas to be maintained or established, and location and description of proposed erosion-control devices or structures.
G. Map drawn with contour intervals (5 foot or less) that adequately depict existing and proposed slope for the proposal.
H. Total quantities, in cubic yards, and type of cut and fill material, including on-site grading material, and imported material. Cross section drawings that include:
   1. Maximum depth of fill and maximum height of cuts.
   2. Existing and proposed buildings and their setbacks from cut or fill slopes.
   3. Existing grades extending a minimum of 20 feet beyond the scope of work.
4. Finished grades of cuts and fills extending a minimum of 20 feet beyond the scope of work.
5. Retaining walls and the adjacent grade at least 20 feet on either side of the wall(s).
6. Grades of all existing cut and fill areas expressed as a ratio of horizontal to vertical slope.

I. The disposal site for excavated material. Off-site disposal may require a separate grading permit.

J. The location of proposed erosion and sedimentation control measures showing compliance with the requirements of SCC Section 24.02.090.

K. Detailed plans of all surface and subsurface drainage devices, walls, cribbing, dams, berms, settling ponds, or other water or erosion control devices to be utilized as a part of the proposed work.

L. Any recommendations included in an engineering geology or geotechnical assessment or report for grading or developing the property. If required, assessment and reports shall be completed in compliance with SCC Title 21A prior to issuance of a clearing and grading permit.

Finding:
Under Skamania County’s Critical Area Ordinance (Title 21A), the subject parcel is designated as a Class I Erosion Hazard Area due to the soil susceptibility to wind and water erosion and a portion of the subject parcel is designated as a Class II Landslide Hazard Area due to 20% slopes underlain with clay type soils. A geotechnical assessment report is required for the proposed project. The project is further required to have effective erosion control measures in place during all phases of the project.

Conclusion:
The proposal states that an Engineer licensed in the State of Washington will prepare detailed clearing and grading plans that will be submitted to EFSEC for review and approval prior to the start of construction. These plans will substantively comply with SCC Title 24 standards.

24.02.090 Grading Standards
Unless otherwise recommended in an approved soils engineering or engineering geology report, grading shall conform to the following standards. Erosion control measures may be installed as outlined in this title, unless otherwise recommended by a project engineer.

A. Appropriate erosion control measures shall be installed prior to any grading activity. All erosion control measures shall be maintained in place until vegetation is established for suitable erosion and sedimentation control. No sediment from grading operations shall be permitted to leave the site or enter any surface waters or wetlands. If the grading activity timeline includes winter months, then a “winter shutdown” standard for site erosion control will be provided by the applicant.

B. Sites shall have a finished grade that drains away from structural foundations for a minimum of 10 feet.

C. All sites shall be cleaned upon project completion, including installation of permanent native grass seeding, landscaping, or other organic means of erosion control.

D. Cuts or fills of five feet in depth or greater shall be set back from property lines by a minimum of 25 feet. This can be decreased with appropriate
engineering. Setback dimensions shall be horizontal distances measured perpendicular to the site boundary.

E. The top of cut slopes shall not be made nearer to a permit area boundary line than one fifth of the vertical height of cut with a minimum of two feet and a maximum of 10 feet. The setback needs to be increased for any required interceptor drains.

F. The toe to fill slopes shall be made not nearer to the permit area boundary line than one-half the height of the slope with a minimum of two feet and a maximum of 20 feet.

G. The Director may approve alternate setbacks at the request of the applicant. In approving these alternate setbacks, the Director may require an investigation and recommendation by a qualified engineer or engineering geologist to demonstrate that the intent of this section has been satisfied.

H. Any proposed finished slope that is steeper than two horizontal to one vertical shall be engineered.

I. The ground surface shall be prepared to receive fill by removing all organic material, non-complying fill, and scarifying topsoil.

J. Solid Waste as defined in this chapter, and detrimental amounts of organic material shall not be used as fill materials.

K. Fill slopes shall not be constructed on natural or cut slopes steeper than two units horizontal in one unit vertical (50 percent slope) unless the permittee furnishes a geotechnical engineering or an engineering geology report or both, stating that the site has been investigated and giving an opinion that a cut at a steeper slope will be stable and not create a hazard to public or private property.

L. At the request of the applicant, the Director may approve the use of alternate grading standards. These approvals shall be based on sound engineering practices and may require the submittal of additional documentation, reports, or testing.

M. No grading shall obstruct or alter any existing natural drainage way, stream, or any other natural body of water.

N. No grading shall alter or increase surface drainage onto any adjacent properties.

Finding:
The proposal states that an Engineer licensed in the State of Washington will prepare detailed clearing and grading plans that will be submitted to EFSEC for review and approval prior to the start of construction.

Conclusion:
These plans will substantively comply with SCC Title 24 standards.

24.02.100 Grading Inspection
Grading projects for which a permit is required shall be subject to inspection by the Director. A licensed Washington State professional engineer shall provide professional inspections of grading operations if engineering is required elsewhere in this title. An inspection schedule shall be established for each project prior to permit issuance based on the following:

A. A civil engineer shall provide professional inspections within such engineer’s area of technical specialty, which shall consist of observation and review as to the establishment of line, grade and surface drainage of
the development area. If revised plans are required during the course of the work, they shall be prepared by the civil engineer.

B. A geotechnical engineer and/or engineering geologist shall provide professional inspection within such engineer’s area of technical specialty, which shall include observation during grading and testing for required compaction. The engineer shall provide sufficient observation during the preparation of the natural ground and placement in accordance with the conditions of the approved plan and the appropriate requirements of this title. He or she shall also provide professional inspection of any excavation to determine if conditions encountered are in conformance with the approved report or plan. Revised recommendations relating to conditions differing from the approved engineering, geology or geotechnical reports shall be submitted to the permittee, the Department, and the civil engineer.

C. The permittee shall be responsible for the work being performed in accordance with the approved plans and specifications and in conformance with the provisions of the title. When approved by the Director, the permittee may engage consultants, if required, to provide professional inspections on a timely basis. The permittee shall act as a coordinator between the consultants, the contractor and the Department. In the event of changing conditions, the permittee shall be responsible for informing the Department of such change and shall provide revised plans for approval.

D. The Department may inspect the project in various stages of work.

E. If, in the course of fulfilling their respective duties under this title, the civil engineer, geotechnical engineer, or engineering geologist finds that the work is not being done in conformance with this title or approved grading plans, the discrepancies shall be reported in writing within three working days to the permittee and to the Department.

F. If the civil engineer, geotechnical engineer, or engineering geologist of record is changed during grading, the work shall be stopped until the replacement has agreed in writing to accept the responsibility within the area of technical competence for approval upon completion of the work. It shall be the duty of the permittee to notify the Department in writing of such a change prior to the recommencement of such grading.

Finding:
The proposal states that an Engineer licensed in the State of Washington will prepare detailed clearing and grading plans that will be submitted to EFSEC for review and approval prior to the start of construction.

Conclusion:
These plans will substantively comply with SCC Title 24 standards.
Appendix D-2
Land Use Consistency Determination
Skamania County, December 2009
RESOLUTION 2009-54

(Certification of Land Use Consistency Review for the amended application for the
Whistling Ridge Wind Energy Project. This resolution repeals Resolution 2009-22 in its
entirety.)

WHEREAS, Whistling Ridge Energy Project, LLC ("Applicant") filed an Application for Site
Certification ("ASC") to the Washington Energy Facility Site Evaluation Council ("EFSEC") on
March 10, 2009 for the Whistling Ridge Energy Project ("Project") pursuant to RCW 80.50; and

WHEREAS, EFSEC has assumed lead agency status pursuant to the State Environmental Policy
Act, RCW 43.21C for the environmental review of this Project. Skamania County anticipates
participating in the SEPA process; and

WHEREAS, the Applicant filed an amended ASC to EFSEC on October 12, 2009 for the
project; and

WHEREAS, said amended ASC removes all ground disturbing and review uses from any area
within the National Scenic Area jurisdiction; and

WHEREAS, the Skamania County Community Development Director reviewed the amended
ASC to determine the project’s consistency with applicable County land use plans and zoning
ordinances and prepared a Certificate of Land Use Consistency; and

WHEREAS, the Board of County Commissioners have reviewed the Community Development
Director’s Certification of Land Use Consistency for the amended application; and

WHEREAS, the Board of County Commissioners on December 22, 2009 considered the
Community Development Director’s determination at a regularly scheduled public meeting; and

WHEREAS, due notice of the Commissioner’s meeting set forth above has been given as
required by law; and

WHEREAS, the development of the Whistling Ridge Energy Project, if approved, will be
specifically governed by a Site Certification Agreement signed by the Governor and the
Applicant, including conditions of approval developed through the upcoming public process,
including SEPA review; and

WHEREAS, more detailed findings of consistency are included in the Community Development
Director’s Certificate of Land Use Consistency, which is attached hereto and is incorporated
herein by reference as if set forth in full; and

WHEREAS, this resolution repeals Resolution 2009-22 in its entirety; and
NOW THEREFORE, BE IT RESOLVED, the Board of County Commissioners, after due deliberation, adopts the Certificate of Land Use Consistency as a staff report to EFSEC, not a decision, and resolves that the Whistling Ridge Energy Project is consistent with the Skamania County land use plans and applicable zoning ordinances. A representative for Skamania County appointed by the Board of Commissioners is serving as a member of the Siting Council. Consequently, Skamania County does not, at this time, make any findings or determination regarding compliance with any other regulatory requirements or siting standards, and any potential conditions of approval recommended by Skamania County will be made at such time as the SEPA review is completed and after public meetings and hearings have been duly conducted by EFSEC, in accordance with Chapter 80.50 RCW.

PASSED IN REGULAR SESSION this 22nd day of December 2009.

BOARD OF COUNTY COMMISSIONERS
SKAMANIA COUNTY, WASHINGTON

Chairman
Commissioner
Commissioner

ATTEST:

Famely Johnson
Clerk of the Board

APPROVE AS TO FORM ONLY:

Prosecuting Attorney
STAFF REPORT FOR LAND USE CONSISTENCY REVIEW

I. SUMMARY OF PROPOSED ACTION (Project description)

This Land Use Consistency Review Staff Report is to address the application for the Whistling Ridge Energy Project to the Washington State Energy Facility Site Evaluation Council. This is not a land use decision. It is a review to provide guidance to EFSEC as to the proposed project’s potential consistency with Skamania County land use plans and zoning ordinances.

If the application had been submitted to the County, the project would require the following county issued reviews and permits: a SEPA Review, a Conditional Use permit (only for the portion of the project located within the zoned area), Building Permits, Critical Area Review, On-site Septic Permit, Well Drilling Inspection, and a Water Availability Verification Evaluation. Further, a Moratorium Lift application would be required as the alternative location for the Operations and Maintenance Building is located on tax parcel #03-09-00-0-0-0100-00, which currently has a Forest Practice Moratorium on the parcel. This Forest Practice Moratorium applies to the entire parcel and will expire in 2015.

The amended application would include all of the previously mentioned reviews. The project will no longer contain any ground disturbance or reviewable activities within the National Scenic Area.

As originally proposed by the application submitted March 10, 2009 to the Energy Facility Site Evaluation Council (EFSEC), Jason Spadero, President of SDS Lumber Co, and of Whistling Ridge Energy LLC, is proposing a facility, collectively called the Whistling Ridge Energy Project, of up to 50 1.2- to 2.5- MW wind turbines with a total capacity of 75 MW of electricity. The project would be located on a 1,152-acre site in unincorporated Skamania County owned by SDS Co, LLC and Broughton Lumber Company, on the forested ridges of Saddleback Mountain. Each turbine would be up to approximately 426 feet tall to the tops of the blades extended over the tower of the wind turbine. In addition to the turbines, the planned facility would include: electrical transformers, 34.5 kilovolt collector lines and systems (primarily underground), permanent meteorological towers, an Operations and Maintenance facility (including bathrooms and kitchen), a new well for potable water, an on-site septic system, a substation located adjacent to BPA’s existing North Bonneville to Midway 230-kV transmission line, and approximately 2.4 miles of newly-constructed gravel roads. There are 7.9 miles of existing private logging roads and road improvements, 7.8 miles located in the project area and 2.5 miles of access roads or road improvements not in the
project area, but outside of the National Scenic Area boundary. All existing, improved, and new roads will provide access to the wind turbine locations during construction and for operations and maintenance.

An amendment to this application was submitted to EFSEC on October 12, 2009. The amendment discusses an alternative location for the Operations and Maintenance Building, as well as moving the proposed access road improvements outside of the National Scenic Area boundary. The first proposed location for the Operations and Maintenance building is adjacent to the substation on the project site. The alternative location for the Operations and Maintenance building would be approximately 0.9 miles off site, located on the proposed new connection from Willard Road to West Pit Road. This parcel is owned by Broughton Lumber Co. and is zoned Residential-5 (R5). The maintenance yard was originally proposed as two acres in size as is now proposed as five acres in size.

The original proposal stated that several wind turbines would be placed in a Residential 10 (R10) zoning designation on the project site. While researching the parcels using the County’s Geographic Information System (GIS), legal descriptions and official zoning maps, no R10 zoning designation was found within the project site. This has been corrected in the amended submittal.

The original proposal states that roughly 400 acres of the project site is located within FOR/AG 20 zoning and Residential 10 zoning designations. The referral to Residential 10 zoning has been corrected in the amendment. However, Community Development staff research of the County’s GIS and assessor maps show that approximately 1,036 acres of the project site is unzoned, and approximately 127 acres of the project site is zoned FOR/AG 20. County GIS and assessor maps show the project area to be approximately 1,163 acres, however, this is just an approximation based on legal descriptions since no boundary survey was conducted. This information does not affect the consistency review of the project; rather it is a clarification of the project based on County’s consistency review.

The original proposal further included improvements to roads and intersections within the National Scenic Area in order to provide access to the project site. The roadways affected include Cook Underwood Road, Kollock-Knapp Road, Scoggins Road and private logging road CG2930. The October 12, 2009 amendment cites changes to the access roads that would take any ground disturbing activity outside of the National Scenic Area. Access to the site would now be provided from SR-14 to Cook Underwood Road to Willard Road and through a new connection to West Pit Road. No road improvements or changes would occur within the National Scenic Area boundaries.

The amended application proposes access to the project area via SR-14 to Cook-Underwood Road to Willard Road, with a new connection to West Pit Road. West Pit Road is an existing 2.5-mile-long logging road originally 8-12 feet wide. In summer 2009, the road was widened to approximately 20-26 feet wide. This road passes over a Class V stream with a current culvert, which will need to be widened as well.

Improvements to the county roadways and the private logging road would be necessary to support the long and heavy loads that would be required for the delivery of the wind energy components from SR 14 to the proposed project site. These improvements may
include 1) Rebuilding large sections of the existing roadway network, 2) Widening certain sections of the existing roadway network, 3) Flattening and/or rebuilding existing roadway topography both horizontally and vertically, and 4) Placing asphalt in select areas for equipment access. All improvements will be located outside of the National Scenic Area.

II. GENERAL INFORMATION

Owner(s): SDS Lumber Co  Broughton Lumber Co
PO Box 266  92 Office Road
Bingen, WA  Underwood, WA
98605  98651

Applicant(s)/Applicant(s)
Representative: Jason Spadero, President, SDS Lumber Co
and Whistling Ridge Energy, LLC
PO Box 266
Bingen, WA 98605

Tax Parcel Number(s):
03-10-00-0-0-0300-00 (portion)
03-10-00-0-0-0400-00 (full)
03-10-00-0-0-0800-00 (portion)
03-10-00-0-0-1100-00 (portion)
03-09-00-0-0-2990-00 (portion)
03-09-00-0-0-0100-00 (alternative location for the Operations & Maintenance Building)
Skamania County Road Right-of-Way

Location: The subject parcels are located in the eastern portion of Skamania T3N, R10E & T3N, R9E, W.M.

Zoning: 127 acres of the proposed project area is zoned FA20. The alternative location of the Operations & Maintenance Building is zoned R5. The remaining 1,036 acres is un-zoned.

Comprehensive Plan Designation: Conservancy (outside NSA)

Square Footage/Acreage: The entire project area is located outside of the NSA and is 1,152 acres (1,163 acres by County calculations), spanning portions of five parcels. If the alternative location for the Operations & Maintenance Building is used, it will span six parcels. Approximately 384 acres would be developed for the wind turbine foundations, connecting roadways, and overhead and underground transmission lines.

Proposed Use: Semi-public utility facility

Number of Lots: The project area spans portions of five parcels. If the alternative location for the Operations & Maintenance Building is used, it will span six parcels.
Density: N/A
Sanitary Sewer District: Individual On-Site Septic System for proposed Operations and Maintenance Facility
Domestic Water Supplies: Applicant is proposing an individual well to serve the kitchen and bathroom facilities in the Operations and Maintenance Building.
Fire District: Fire District #3
School District: #31 Mill A and White Salmon School Districts
Drainage Basin: Wind / White Salmon
WR1A: Wind / White Salmon
WR1A Number: 29B

III. HISTORY/BACKGROUND:
Skamania County is one of ten counties in Washington State that is not required to fully plan under the Growth Management Act. The County is not required to establish zoning classifications on all the land within its jurisdiction.

The 2007 Comprehensive Plan applies to all unincorporated land within Skamania County. Not all of unincorporated Skamania County has a zoning classification. The critical area regulations only apply outside of the NSA.

SDS Co. LLC submitted their application for the Whistling Ridge Energy Project on March 10, 2009. SDS Co. submitted an amended application to EFSEC on October 12, 2009. Skamania County Community Development Department is providing EFSEC with a consistency review of all county regulations that apply to the project. The County is not providing a decision on this project at this time.

The original application included roadway improvements on roads located within the National Scenic Area. The amended application has removed any roadway improvements and ground disturbing activity inside of the NSA. Therefore, portions of the previous staff report relating to the NSA activity, no longer apply.

IV. SEPA THRESHOLD DETERMINATION:
EFSEC issued a scoping notice on April 6, 2009 to begin the EIS review process. A revised notice was issued April 21, 2009.

V. PUBLIC HEARING NOTICE:
EFSEC published all required notices.

VI. NATURAL ENVIRONMENT
A. Topography:
The resource maps indicate that the subject parcels within the project area, have slopes ranging from zero percent to over 40%. Under Skamania County's Critical Areas Ordinance (Title 21A), the subject parcels are located in a Class II Landslide Hazard Area. As such, this requires a geotechnical assessment report be completed for the proposed project. A geotechnical assessment report is
prepared by a Washington state licensed hydrologist or geologist and requires the following, at minimum:

a. A description of the topography, surface and subsurface hydrology, soils geology, and vegetation of the site;
b. An evaluation of the analysis area’s inherent erosion hazards;
c. A site plan of the area delineating all areas of the site subject to erosion hazard; and
d. Proposed mitigation measures to be implemented by the applicant, including, but not limited to, minimizing site disturbance or grading, implementing erosion control measures, such as the retention of existing vegetation and controlling surface water drainage through stormwater retention and detention systems.

B. Soils:
According to the Natural Resources Conservation Service (NRCS) Soil Survey of Skamania County, the soil types of the parcels are: McElroy gravelly loam (types 66, 67, 68), Timberhead gravelly loam (types 135, 136), Underwood loam (type 144). Each of these soils has a T Factor of 5. Under Skamania County’s Critical Areas Ordinance, Title 21A, the subject parcels are located in a Class I Erosion Hazard Area.

C. Surface Water:
Within the proposed project area there is: One (1) Class 4N stream; 19 Class 5N streams; and five (5) unclassified streams.

D. Vegetation:
The project area is covered by second and third growth commercial timber stands.

E. Wildlife:
The entire project area is within Elk winter range habitat. No other habitat was found on resource maps.

F. Sensitive Areas:
No Sensitive Areas were found on the Resource maps within the proposed project area. No known cultural or archaeological resources were found within the project area.

VII. NEIGHBORHOOD CHARACTERISTICS
The Comprehensive Plan designation of this project area is Conservancy. The alternative location for the Operations and Maintenance Building is within Rural Lands II Comprehensive Plan designation. Some of the surrounding area is Rural Lands II, with the majority being Conservancy.

The southern project boundary line (including the southeast project line) borders the Columbia River Gorge National Scenic Area, but is not within the National Scenic Area.
VIII. TRANSPORTATION PLANS
The original proposed access was from State Route 14 to Cook-Underwood Road, to Kollock-Knapp Road to Scoggins Road. This would have required road improvements within the National Scenic Area. The amended application has access to the proposed site provided from State Route 14 to Cook-Underwood Road, to Willard Road and through a proposed new connection to existing West Pit Road, located on SDS Lumber Company and Broughton Lumber Company property. The alternative Operations & Maintenance building location would be accessed off of Willard Road.

IX. UTILITIES
A. Stormwater:
Discharge of stormwater runoff would be regulated by EFSEC based on the Department of Ecology’s stormwater pollution control program. The proposal indicates mitigation measures by Best Management Practices and by implementing a Stormwater Pollution Prevention Plan (SWPPP) during and after construction. The final design would conform to the applicable Ecology Stormwater Management Manual in effect at the time or as instructed by EFSEC.

B. Wastewater Disposal:
The Applicant is required to apply for an On-Site Septic System permit as the Operations and Maintenance Building will include bathroom and kitchen facilities. Prior to issuance of any building permit, the applicant is required to have an approved On-Site Septic System Design.

C. Potable Water:
Prior to the issuance of a building permit for the proposed Operations and Maintenance Building, the applicant is required to have an approved Water Availability Verification Evaluation (WAVE).

X. COMPREHENSIVE PLAN
The following Goals and Policies of the Skamania County Comprehensive Plan are applicable to the proposed project.

Chapter 2: Land Use Element
Goals and Policies
Conservancy Designation

Goal LU.1: To integrate long-range considerations (comprehensive planning) into the determinations of short-term action (individual development applications).

Policy LU.1.2: The plan is created on the premise that the land use areas designated are each best suited for the uses proposed therein. However, it is not the intention of this plan to foreclose on future opportunities that may be made possibly by technical innovations, new ideas and changing attitudes. Therefore, other uses that are similar to the uses listed here should be allowable uses, review uses or conditional uses, only if the use is specifically listed in the official controls of Skamania County for that particular land use designation.

Finding:
The project area lies within the Conservancy Comprehensive Plan Designation. The alternative location for the Operation and Maintenance Building lies within the Rural Lands II Comprehensive Plan Designation. Within the conservation designation and the Rural Lands II designation, public facilities and utilities, and utility substations are allowed.

**Conclusion:**
The project is considered a semi-public utility facility and would therefore be consistent with the Conservancy Designation.

**Goal LU.3:** To coordinate public and private interests in land development.

**Policy LU.3.3:** Encourage industry that would have minimal adverse environmental or aesthetic effects.

**Finding:**
The project area is located outside of the Columbia River Gorge National Scenic Area boundary. The turbines would be painted gray to minimize aesthetic effects. The proposed project would be located within an area where roadways and high voltage regional transmission lines already exist, which would minimize the need for new disturbances.

**Conclusion:**
The project is consistent with this goal and policy.

**Goal LU.4:** To promote interagency cooperation and effective planning and scheduling of improvements and activities so as to avoid conflicts, duplication and waste.

**Policy LU.4.3:** Land use patterns, which minimize the cost of providing adequate levels of public services and infrastructure, should be encouraged.

**Finding:**
High-voltage regional transmission lines, owned and operated by Bonneville Power Administration (BPA) are located on the project site. Access roadways already exist, with the exception of the proposed connection from Willard Road to West Pit Road. The project uses existing patterns in Land Use, which helps to minimize the public costs of providing services and new infrastructure.

**Conclusion:**
The project is consistent with this goal and policy.

**Goal LU.5:** To promote improvements which make our communities more livable, healthy, safe and efficient.

**Policy LU.5.5:** Promote compatibility of industry with the surrounding area or community by fostering good quality site planning, landscaping, architectural design, and a high level of environmental standards.
Policy LU.5.7: Adequate on-site wells and septic systems should be properly installed, monitored and maintained in accordance with local and state health departments.

Finding:
The proposed project is located in the Conservancy Designation, which allows for public utility facilities and utility stations. The surrounding areas are Conservancy Designation, as well as Rural Lands II Designation, which also allows for utility facilities and utility substations. The project site has been previously logged by forestry activities and the proposal would allow the forestry activities to continue. High-voltage transmission lines, cell towers and rock quarries currently exist in the area, so the project would be compatible with these uses.

The proposed Operations and Maintenance Building is located in the Rural Lands II Designation, which allows for public utility facilities and utility stations. It would include bathroom and kitchen facilities and would therefore be required to have an approved on-site septic system as well as an adequate potable water supply. If/when an application is submitted to this department, this would be a condition of approval.

Conclusion:
The project is consistent with the goals and policies. A valid OSS and proof of potable water would be a condition of approval.

Chapter 3: Environmental Element
Goals and Policies

Goal E.1: To ensure the proper management of the natural environment to protect critical areas and conserve land, air, water and energy resources.

Policy E.1.4: Implement and preserve critical area buffers based on Best Available Science adjacent to critical areas to adequately protect such areas from development and land use impacts.

Finding:
Several streams exist on the proposed project site, with buffers ranging from 25’ to 50’, which must be maintained at all times unless exemptions are met or variances are granted.

Conclusion:
This proposal is consistent with the goals and policies.

Goal E.3: To minimize the loss of life and property from landslides, seismic, volcanic or other naturally occurring events, and minimize or eliminate land use impacts on geologically hazardous areas.

Policy E.3.4: Require geotechnical studies to determine construction methods and technologies necessary to further public safety in geologically hazardous areas. The development design and construction technology used shall be appropriate to the soil limitations on the particular site.
Finding:
The project should require a geotechnical assessment report and soil borings to be conducted on-site. The report should be reviewed and accepted by Skamania County prior to issuing any building permits. Any and all setbacks determined within the report must be followed.

The proponent had a geotechnical assessment report prepared for this project. At this time, the report has not been reviewed by Skamania County.

Conclusion:
The project is consistent with these goals and policies.

Chapter 4: Transportation Element

Goal T.1: Transportation – Encourage an efficient multi-modal transportation network that is based on regional priorities and coordinated with county and city comprehensive plans.

Goal T.3: Public Facilities and Services – Ensure that those public facilities and services necessary to support development should be adequate to serve the development at the time the development is available for occupancy and use without decreasing current service levels below locally established minimum standards.

Finding:
Most roadways that will be used for this proposal exist and some improvement will be necessary for the transportation of the equipment and construction materials. A short road span connecting West Pit Road to Willard Road is proposed for access to the site. Other proposed roadways for the site will be located on the project site. Some intersection improvements are needed to allow safe turning of construction and equipment delivery vehicles. These improvements, as well as the added traffic, would not degrade the existing levels of service at nearby intersections below minimum standards. The applicant should consult with the Skamania County Public Works Department regarding the sufficiency of roads. Turbine equipment would likely be transported to either the Port of Longview or the Port of Vancouver, and much of it transported by barge up the Columbia River to the Applicant’s existing barge and dock facilities in Bingen, Washington. If rail is used, it will be by existing rail lines.

Conclusion:
This proposal is consist with these goals and policies. The road improvements will enhance the level of service on these roads and benefit the community.

Chapter 5: Archaeology and Historic Preservation Element

Goal AHP.1: Identify and encourage the preservation of lands, sites, and structures that have historical or archaeological significance:

Policy AHP.1.3: Coordinate county inventory efforts with Native American groups and governmental efforts.
Finding:
Research conducted by Skamania County Community Development found no archaeological or historical resources located on the project area. CH2M HILL conducted an intensive cultural resource inventory survey of the proposed area of potential effect in August 2003. No evidence of prehistoric activity was observed and no archaeological sites or historic properties were identified, although two historic archaeological isolates were found and documented, consisting of piled basalt cobbles and scatter of historic debris previously disturbed by power line construction and logging. No known archaeological or cultural resources were found on the Washington State Department of Archaeological and Historic Preservation (DAHP) resource maps that staff used to research the project area.

Further, if the project proponent applies for a Conditional Use permit, the application would be sent to various state agencies, federal agencies, and Native American Governments, allowing the opportunity to comment on the project. EFSEC should consult with these groups during the process.

Conclusion:
This project is consistent with these goals and policies.

Goal AHP.3: Protect historic, archaeological, and cultural resources through a comprehensive planning approach.

Finding:
Research conducted by Skamania County Community Development found no archaeological or historical resources located on the project area. CH2M HILL conducted an intensive cultural resource inventory survey of the proposed area of potential effect in August 2003. No evidence of prehistoric activity was observed and no archaeological sites or historic properties were identified, although two historic archaeological isolates were found and documented, consisting of piled basalt cobbles and scatter of historic debris previously disturbed by power line construction and logging.

Conclusion:
This project is consistent with these goals and policies.

XI. STATUTES/CODES:

Skamania County Code Title 21 – Zoning

Chapter 21.64 – Unmapped Classification (UNM)

21.64.020 – Allowable Uses
In the areas classified as Unmapped, all uses which have not been declared a nuisance by statute, resolution, ordinance, or court of jurisdiction are allowable. The standards, provisions, and conditions of this title shall not apply to unmapped areas.

Finding:
1,036 acres of this project is unzoned and therefore there are no restricted uses. Utility facilities and utility substations have not been declared a nuisance by a known Washington State Court or by local ordinance or resolution or by any known state or federal statutes.

**Conclusion:**
The project is consistent with the zoning designation of UNM.

*Chapter 21.56 – Resource Production Zone Classification (FOR/AG 10 & 20)*  
21.56.030 – Conditional Uses  
(C) Semi-public facilities and utilities

**Finding:**  
Approximately 127 acres of this project is located within the FOR/AG 20 zoning classification. The “A” string of the project within this zoning classification. The “A” string includes seven turbines. All other proposed turbines are outside of the zoned area. Semi-public facilities and utilities are a conditional use within this zoning designation. The applicant would need to submit a conditional use application for review by the Hearing Examiner for approval of this project if the County was conducting the project review. Conditional use permits are reviewed and issued by the County Hearing Examiner.

*Chapter 21.36 – Residential 5 Zone Classification (R5)*  
21.36.031 – Conditional Uses  
(G) Semi-public facilities

**Finding:**  
The proposed alternative location for the Operations and Maintenance Building is located approximately 0.9 acres from the project site on a parcel zoned Residential 5. The proposed maintenance yard would be approximately 5 acres. Semi-public facilities are a conditional use within this zoning designation. The applicant would need to submit a conditional use application for review by the Hearing Examiner for approval of this project if the County was conducting the project review. Conditional use permits are reviewed and issued by the County Hearing Examiner.

21.16.070 - Hearing Examiner - Duties and Responsibilities  
The Hearing Examiner shall hear and decide:  
A. Applications for conditional uses. Conditional uses are those uses, which may or may not be compatible with permitted uses in a specific zoning designation. If the Hearing Examiner determines the use is not compatible with permitted or existing uses in the specific area of the proposed use then the proposed use shall be denied. Alternatively, if the Hearing Examiner determines that the proposed use is compatible with permitted and existing uses in the specific area of the proposed use then the proposed use may be approved or approved with conditions to make it compatible with the area.

1. In determining whether the use is compatible with the area, the proposed use shall:
a. Be either compatible with other uses in the surrounding area or is no more incompatible than are other outright permitted uses in the applicable zoning district;

Finding:
The proposal is to install up to 50 wind turbines on a parcel of land in unincorporated Skamania County, 1,036 acres are unzoned, and 127 acres are zoned FOR/AG 20. The Operations and Maintenance Building will either be located on the project site adjacent to the substation or in an area off Willard Road approximately 0.9 miles from the project area and is zoned R5. The entire proposal is located within the Conservancy Comprehensive Plan Designation, with the exception of the alternative location for the Operations and Maintenance building which is located in Rural Lands II.

Unzoned areas of Skamania County and the Conservancy Comprehensive Plan Designation allow for public utility facilities and utility substations. The FOR/AG 20 and the R5 zoning districts list semi-public utility facilities and utility substations as a conditional use and allow public facilities outright with no additional zoning review being required.

The surrounding areas are located within the Conservancy Designation, as well as the Rural Lands II Designation, both of which allow public utility facilities and utility substations. The property is currently uses for commercial forestry activities, and these activities will be allowed to continue once the turbines are constructed. Cell towers, high-voltage transmission lines and rock quarries exist in the area. There is a small portion of the project site that abuts Residential 10 (R10) zoning, which also lists semi-public utilities as conditional use.

Conclusion:
The proposal is compatible with other uses within the area, both within the Comprehensive plan designation and the zoning designation.

b. Not materially endanger the health, safety, and welfare of the surrounding community to an extent greater than that associated with other permitted uses in the applicable zoning district.

Finding:
The subject parcel is located in a geological hazard area due to the slope and soil type and requires a geotechnical assessment report.

The applicant is required to show proof of potable water and obtain an on-site septic system permit from the Skamania County Community Development Department through the building permit process. The proposal includes bathroom and kitchen facilities located in the Operation and Maintenance Building.

EFSEC has required an EIS to be prepared and will ultimately decide what conditions of approval would be necessary for the project to be found to not materially endanger the health, safety and welfare of the surrounding
community. By obtaining the water, septic and building permits, conducting the geotechnical analysis and best management practices during construction, the project could be found consistent with this provision.

**Conclusion:**
The proposal will not materially endanger the health, safety, and welfare of the surrounding community.

c. *Not cause the pedestrian and vehicular traffic associated with the use to conflict with existing and anticipated traffic in the neighborhood to an extent greater than that associated with other permitted uses in the applicable zoning district.*

**Finding:**
Access of the proposed site would be provided from State Route 14 to Cook-Underwood Road, Willard Road and with a new connection to existing West Pit Road, located on SDS Lumber Company and Broughton Lumber Company property.

All roadways that will be used for this proposal exist, with the exception of the new connection from Willard to West Pit Road and access roads within the project site boundaries, and some improvement will be necessary for the transportation of the equipment and construction materials. Some intersection improvements are needed to allow safe turning of construction and equipment delivery vehicles. These improvements, as well as the added traffic, would not degrade the existing levels of service at nearby intersections below minimum standards. The applicant will consult with the Skamania County Public Works Department regarding the sufficiency of roads and road upgrade requirement. Other permitted uses include: single family residences in conjunction with forest or farm management, recreational facilities, semi-public facilities and utilities, saw mills, shake and shingle mills, chippers, pole and log yards, geothermal energy facilities, aircraft landing fields, cluster developments, child mini day care centers, and child day care centers.

**Conclusion:**
The proposal will not cause a conflict with existing pedestrian and vehicular traffic.

d. *Be supported by adequate service facilities and would not adversely affect public services to the surrounding area.*

**Finding:**
The proposal states that an Engineering, Procurement, and Construction (EPC) contractor will prepare a safety plan that would apply to all personnel working on-site. The plan would ensure compliance will all laws, ordinances, regulations and standards concerning health and safety. An Environmental Compliance Program would cover avoidance of sensitive areas during construction, waste handling and storage, stormwater management, spill prevention and control, and other components required by State and County regulations. An Emergency Response Plan would be established to ensure employee safety from the
following: medical emergency, major power loss, fire, extreme weather, earthquake, volcano, and bomb threat. This plan would be established prior to construction.

**Condition:**
All safety plans and programs are required to be in place prior to construction. These plans and programs should be included as a conditional of approval.

   e. *Not hinder or discourage the development of permitted uses on neighboring properties in the applicable zoning district as a result of the location, size, or height of the buildings, structures, walls, or required fences or screening vegetation to a greater extent than other permitted uses in the applicable zoning district.*

**Finding:**
The proposal is to install up to 50 wind turbine structures on a project site spanning portions of five parcels. This use is classified as a semi-public utility facility within the FOR/AG 20 zoning designation. If the alternative location for the Operations and Maintenance building were selected, the project would span six parcels. This use is classified as a semi-public utility facility within the R5 zoning designation.

Other uses in the FOR/AG 20 zoning designation include, among others: forestry practices and associated management activities of forest crop, commercial and domestic agriculture, water resource management facilities, log sorting and storage areas, etc. Other uses in the R5 zoning designation include, among others: single-family dwellings, commercial and domestic agriculture, public facility and utilities, and accessory equipment structures, etc.

Surrounding zoning includes FOR/AG 20, as well as R10 (Residential 10) and R5 outside of the NSA. To the south of the project area, inside the NSA, the surrounding area is zoned Large Scale Agriculture, Commercial Forest, Small Woodland and Open Space. Current uses surrounding the project site include commercial forestry uses, agriculture including pear and apple orchards, and three small, unincorporated residential communities and other agriculture related dwellings.

**Conclusion:**
The proposal is compatible with other uses in the region and will not affect the allowed uses on those parcels. The proposal states commercial forestry activities will likely continue on the project site parcels as well.

   f. *Not be in conflict with the goals and policies expressed in the current version of the County's comprehensive plan.*

**Finding:**
As discussed above, the proposal is consistent with the Skamania County Comprehensive Plan.
2. Criteria for determining conditions to be imposed on conditional uses shall be based on the health, safety, and general welfare of the public, any environmental standards in force in Skamania County, other applicable provisions set forth in this Title and shall be subject to conditions which may include, but are not limited to the following:

   a. Limiting the manner in which the use is conducted including restricting the time an activity may take place, and restraints to minimize such environmental effects as noise, vibration, air pollution, glare, and odor.

Finding:
The EIS and EFSEC will determine what conditions, if any, are required to be implemented for this project.

   b. Establishing a special yard, open space, lot area or lot dimensions.

Finding:
Not applicable

   c. Limiting the height, size, or location of a building or other structure.

Finding:
127 acres of this project site, which includes seven proposed turbines, is located within FOR/AG 20 zoning designation. Under the current FOR/AG 20 zoning designation, the required front yard setback is 35-feet from the centerline of the private road or 20-feet from the front property line with the front defined as the line which parallels a public road right-of-way or a private road easement, or that line where a road, driveway, or access panhandle enters a lot. The required rear setback under the current regulations is 20-feet from the rear lot line with the rear defined as the lot line which is opposite and farthest away from the front lot line.

The alternative location for the Operations and Maintenance building is on land designated Residential 5 (R-5). Under the current R5 zoning designation, the required front yard setback is 50-feet from the centerline of the public road right-of-way or 35-feet from the centerline of a private road right-of-way, or 20-feet from the property line, whichever is greater. The required rear setback is 20-feet and the required side yard setbacks are 20-feet.

The remainder of this parcel, 1,036 acres, is unzoned and therefore has setbacks as determined by the Building code list from Title 15. Building Code setback requirements for un-zoned lots 12,500 square feet or larger is:
Front Yard: No building or accessory building shall be constructed closer than 45 feet from the centerline of the public road right-of-way or 35 feet from the centerline of the private road (note including private driveways), or road or 15 feet from the front property line, whichever is greater;
Side Yard: On each side of the building or accessory building a side yard shall be provided for not less than 5 feet; and
Rear Yard: A rear yard shall be provided of not less than 15 feet, including accessory buildings.

Conclusion:
Under the current regulations, the proposed location meets the minimum requirements. However, EFSEC may require additional setbacks or micro siting of turbines.

d. Designating the size, number, location, and nature of vehicle access points.

Finding:
No new major roads are proposed at this time. Only a small connection from Willard Road to West Pit Road will be constructed for access. Other proposed roads include access roads within project boundaries. The EIS traffic studies and road design plan will determine any requirements for vehicle access points.

e. Increasing the amount of street dedication, roadway width, or improvements within the street right-of-way.

Finding:
The EIS traffic studies and road design plans will determine the necessary road improvements. No new roads are proposed at this time, other than the short connection from Willard Road to West Pit Road and roads within project boundaries.

f. Limiting or otherwise designating the number, size, location, height, and lighting of signs.

Finding:
Non-applicable

g. Limiting the location and intensity of outdoor lighting and requiring it to be shielded.

Finding:
Lighting of turbine strings will need to meet Federal Aviation Administration (FAA) requirements. Lighting on buildings is requested to be hooded and shielded. This is a request and not currently a requirement in the County zoning code.

h. Requiring berming, screening, landscaping, or another facility to protect adjacent or nearby properties and designating standards for its installation and maintenance.

Finding:
The residences closest to the project site are located approximately 0.48 mile and 0.8 mile from proposed turbine locations. A new home site location has been applied for, and would be approximately 2,000 feet (0.38 Mile) from the south property line. The unincorporated community of Willard is located approximately
2.25 miles northwest of the project site. The unincorporated community of Mill A is also located near the project site, approximately 1.5 miles west of the site. The homes near the project site are rural, primarily single family, between 30 and 50 years old, and low- to medium-density.

The residence closest to the alternative location for the Operations and Maintenance building is approximately 0.25 miles.

**Conclusion:**
In order to protect adjacent and nearby properties, the applicant should only excavate the minimum needed to install the wind turbines and accessory structures, and the Operations and Maintenance facility, maintain existing trees, and re-vegetate all undeveloped disturbed areas with native trees and shrubs along the west and south lot lines. However, since this land is being used for Commercial Forestry, the removal of timber in conjunction with this operation should not be restricted.

1. *Designating the height, location, and materials for a fence.*

**Finding:**
EFSEC will determine if any fencing is required for safety and/or aesthetic reasons.

2. *Protecting and preserving existing trees, vegetation, water resources, wildlife habitat, or other significant natural, historic, or cultural resources.*

**Finding:**
The proposed project is located within a Class II Landslide Hazard Area and a Class I Erosion Hazard Area due to the soil type and requires a geotechnical assessment report. The entire project site is also located within elk winter range habitat. Several streams exist on site, which would require buffers ranging between 25' to 50'. There are no current County requirements to preserve trees or vegetation outside of critical resource stream buffers. No cultural or historic resources found in database research.

**Conclusion:**
In order to prevent possible wind and water erosion, the applicant should use Best Management Practices during all phases of construction and replant all undeveloped disturbed areas with native vegetation. The project requires a geotechnical assessment report to address the landslide hazard on the property. The applicant has already submitted a geotechnical assessment report, which has not been reviewed by the County.

**Skamania County Code Title 21A – Critical Areas**

21A.04.010 - General Provisions

A. *RELATIONSHIP TO SHORELINES MANAGEMENT MASTER PLAN AND SHORELINES MANAGEMENT ACT PERMITS ORDINANCE.*
In event of any conflict between this Title and regulations contained in the Shorelines Ordinance, those regulations that provide greater protection of Critical Areas shall apply.

Finding:
There are several streams located on the subject parcel. The proposal is to erect up to 50 wind turbine structures. No stream located on-site is a Shoreline of Countywide or Statewide significance and therefore the Skamania County Shoreline Management Program does not apply.

Conclusion:
Skamania County Critical Areas Ordinance, Title 21A, provides the greatest protection to the critical areas and only applies outside of the National Scenic Area.

21A.04.030 - STREAMS, CREEKS AND RIVERS
(4) Buffer Widths
(b) ... undisturbed buffers shall be preserved around all regulated streams, creeks and rivers.
(c) The required width of undisturbed buffer areas shall depend upon the class of water represented by the stream, creek or river protected, the type or scale of use or development proposed by an applicant and the vegetative community adjacent to the water body.
   (iv) For Class IV streams, creeks and rivers, the standard buffer zone width shall be 50 feet.
   (v) For Class V streams, creeks and rivers, the standard buffer zone width shall be 25 feet.

Finding:
The proposed project area includes several streams ranging from a 25' to 50' undisturbed buffer requirement. The proposal states that no new construction would occur within wetlands, streams, or associated buffers. Most of the existing road improvements in these regulated fish and wildlife protection areas do not exceed the allowed expansion threshold (100% or less of the original footprint).

West Pit Road is an existing logging road that will be used to access the site. The road was originally 8 to 12 feet in width, and has been widened to approximately 20 to 26 feet in width. Further widening of sections of the road is proposed to 25-feet in width, with 5' shoulders on each side. Also proposed is the widening of the existing culvert across the Class V stream on West Pit Road. No Critical Areas Variance will be required if the expansion/widening is less than 100% of the original size. If the expansion is greater than 100%, a Critical Areas Variance will be required.

Conclusion:
Maintaining critical areas buffers would be a condition of approval. If any expansion of existing roadways or culverts occurs within critical area buffers that are greater than 100% of the original size, a Critical Areas Variance will be required.
The applicant has already had a wetland delineation report prepared for the project. This report has not been reviewed by Skamania County at this time.

21A.05.050 – Fences in Deer and Elk Winter Range
(A) New development permits issued by the County shall include a requirement that, in deer and elk winter range, construction of new and replacement fences shall be subject to the following:

1. New fences in deer and elk winter range shall be allowed only when necessary to control livestock or pets or to exclude wildlife from specified areas, such as gardens or orchards. Fenced areas shall be the minimum necessary to meet the needs of the project applicant.

2. New and replacement fences in winter range shall comply with the following, unless the applicant demonstrates the need for an alternative design:
   a. The top wire shall not be more than 42 inches high to make it easier for deer to jump over the fence.
   b. The distance between the top two wires shall be at least 10 inches to make it easier for deer and to free themselves if they become entangled.
   c. The bottom wire shall be at least 16 inches above the ground to allow fawns to crawl under the fence. It should consist of smooth wire because barbs often injure animals as they crawl under the fence.
   d. Stays or braces placed between strands of wire shall be positioned between fence posts where deer are most likely to cross. Stays create a more rigid fence, which allows deer a better change to wiggle free if their hind legs become caught between the top two wires.

3. Woven wire fences may be authorized only when a project applicant clearly demonstrates that such a fence is required to meet his or her specific needs, such as controlling hogs and sheep.

Finding:
EFSEC will determine if any fencing is required for safety and/or aesthetic reasons.

Conclusion:
If EFSEC requires fencing, a condition of approval would be to follow the above guidelines for fencing within deer and elk winter range.

The proponent has already had a wildlife survey completed. This report has not been reviewed by Skamania County at this time.

21A.06 Geologically Hazardous Areas
21A.06.010 Erosion Hazard Areas
   A. Class I Erosion Hazard Areas:
Class I Erosion Hazard Areas (EHAs) are areas that are subject to severe development constraints due to a site's susceptibility to erosion from wind and/or water.

Class I EHAs are identified in the Soil Survey of Skamania County Areas, Washington, prepared by the United States Department of Agriculture, Soil Conservation Service, as having an index of greater than or equal to 3.75.

21A.06.020 Landslide Hazard Areas
A. Class II Landslide Hazard Areas (LHAs) are areas with slopes 20% and 30% that are underlain by soils that consist largely of silt, clay or bedrock, and all areas with slopes greater than 30%.

Class II LHAs shall be identified using the Soil Survey of Skamania County Areas, Washington, prepared by the United States Department of Agriculture, Soil Conservation Service. Department personnel shall make a preliminary determination of percentage of slope. The applicant shall verify soil type and precise percentage of slope.

Finding:
The proposed project site is located within a Class I Erosion Hazard Area and a Class II Landslide Hazard Area under Skamania County Critical Areas Ordinance Title 21A. The resource maps indicate that the subject parcels have slopes ranging from zero percent to over 40%. As such, this requires a geotechnical assessment report be completed for the proposed project. A geotechnical assessment report is prepared by a Washington state licensed hydrologist or geologist and requires the following, at minimum:

a. A description of the topography, surface and subsurface hydrology, soils geology, and vegetation of the site;
b. An evaluation of the analysis area's inherent erosion hazards;
c. A site plan of the area delineating all areas of the site subject to erosion hazard; and
d. Proposed mitigation measures to be implemented by the applicant, including, but not limited to, minimizing site disturbance or grading, implementing erosion control measures, such as the retention of existing vegetation and controlling surface water drainage through stormwater retention and detention systems.

Conclusion:
The proposal discusses submitting a geotechnical assessment report and performing soil borings on site. This report must be reviewed and approved by Skamania County and would be a condition of approval.

The applicant submitted a Geotechnical Assessment Report, which has not been reviewed by the County at this time.
Skamania County Code Title 22 – National Scenic Area

The original proposal included road improvements on existing roadways within the National Scenic Area. However, the amended proposal changes the access roads and road improvements to roadways not located within the National Scenic Area. Therefore, as currently proposed, no National Scenic Area review would be completed and is not required.

Skamania County Code Title 24 – Clearing & Grading

24.02.50 Applicability

Unless exempted under SCC Section 24.02.060, no person shall perform any grading activity without having first obtained a permit from the Department. Exemption from the permit process shall not relieve any person the requirement for installation of appropriate erosion control measures for their project. No permit or exemption granted pursuant to this title shall remove an applicant’s obligation to comply in all respects with the applicable provisions of any other federal, state, or local law or regulation.

24.02.060 Exemptions

The following activities are exempt from the permit requirements of this title. Materials from exempted excavations may require a separate permit for placement as fill.

A. Mining, quarrying, excavating, processing, or stockpiling activities of rock, sand, gravel, or clay if such operations are authorized by a valid Department of Natural Resources Surface Mine Reclamation Permit or Skamania County Conditional Use Permit or other provision of Skamania County Code.

B. All State Department of Natural Resources regulated Class I, II, III, or IV special forest practice activity conducted in accordance with Chapter 76.09 RCW and WAC Title 222.

C. Grading, clearing, filling or excavation of less than 500 cubic yards, only if located outside Critical Areas (SCC Title 21A) and regulated Shorelines (SCC Title 20).

D. Emergency actions which must be undertaken immediately or for which there is insufficient time for full compliance with this title in the event that:

   1. There is an imminent threat to public health or safety,
   2. There is imminent danger to public or private property;
   3. There is an imminent threat of serious environmental degradation;

   a. A person or agency determines that the need to take emergency action is so urgent that there is not sufficient time for review by the Department; such emergency action may be taken immediately. Any person or agency undertaking such action shall notify the Department within one working day following the commencement of the emergency action. Following such notification the Department shall determine if the action taken was within the scope of the emergency actions allowed in this subsection. If the Department determines that the action taken or part of the action taken is beyond the scope of allowed emergency action, enforcement action is authorized, as outlined in SCC Section 24.02.120.
b. If the action taken qualifies as an emergency, and would have otherwise required a grading permit under this Title, then an application for a grading permit will be submitted with in 30 days following the emergency event. The application requirements, review, issuance, and inspections will be conditioned as outlined in this Title.

E. All exemptions as enumerated in the Critical Area and Shoreline Ordinances.

F. Nothing herein may interfere or overrule the Right to Farm Ordinance.

G. Nothing in this ordinance shall be retroactive and all current projects are hereby vested

Finding:
The proposal will include excavation work to install concrete foundations with a diameter of up to approximately 60 feet for each wind turbine. The Collector System will disturb an area approximately 30 feet in width, with 8.5 miles of underground collector cable trenches proposed. Approximately 2.4 miles of new gravel access roads will be constructed for construction, maintenance and operation as part of the proposal.

Conclusion:
As the volume and area of the clearing activities exceeds the exemption amount of volume and/or area, the applicant/property owner is required to obtain a Clearing and Grading Permit under SCC Section 24.02.050. EFSEC will make a determination on what conditions of approval are necessary.

24.02.070 Application Requirements
Unless exempted under SCC Section 24.02.060, all persons proposing to conduct grading and/or clearing activity within the jurisdictional boundaries of unincorporated Skamania County shall first apply for a grading permit. The applicant shall obtain a grading permit in conformance with this title prior to any grading activity.

A. The permit application shall at a minimum include the following:

1. A completed application, signed by the property owner and the applicant, a vicinity map, environmental checklist (if required), and any relevant supplemental information required by the Director.

2. Grading plans as described in SCC Section 24.02.080.

3. A full identification and written description of the work to be covered by the permit for which the application is made.

4. A timeline for completion of the project.

5. Non-refundable application fee as determined by resolution of the Board of County Commissioners.

Finding:
The applicant/property owner does not meet the exempt criteria for a Clearing and grading permit and is therefore required to submit a Clearing and Grading permit application.

Conclusion:
The proposed project will require a Clear and Grading permit application, which would be a condition of approval.
The proposal states that an Engineer licensed in the State of Washington will prepare detailed clearing and grading plans that will be submitted to EFSEC for review and approval prior to the start of construction. These plans will substantively comply with SCC Title 24 standards.

A. Granting of Permits

1. After an application has been filed and reviewed the Director shall ascertain whether such proposed grading work complies with the provisions of this title. If the application and plans so comply, or if they are corrected or amended so as to comply, and the proposal is consistent with all other relevant county codes, the Director shall issue a grading permit.

2. The applicant/property owner shall maintain the approved grading plans and permit available on the site, and provide an individual copy to any grading contractor who will be working at the site.

3. A grading permit shall be valid for a period of two years from the date of permit issuance, only for the grading work applied for. An extension may be granted for an additional 12 months for special circumstances. Request for extensions shall be submitted in writing to the Department prior to expiration of the current permit, setting forth the reasons and justification for the request. No permit may be extended more than once. Renewal of permits may be accomplished with existing plans and reports, if no changes are being made to the proposal, and no new significant issues are raised during the review.

Conclusion:
In order to be in compliance with this section of the Clearing and Grading Ordinance, a condition of approval should be that the permit and grading plans are available on site and that the grading permit is valid for two years.

24.02.080 Grading Plan
An application for clearing and grading shall be accompanied by a grading plan. If the clearing and grading project involves engineered grading, than an engineered grading plan based on an engineering report or an engineering geology report shall be submitted with the application. Engineered grading plans shall be prepared and stamped by an engineering geologist, geotechnical engineer and/or civil engineer licensed to work in the State of Washington. Grading within a geological hazard critical area may require a geotechnical assessment report in compliance with the Critical Area Protection Ordinance (SCC Title 21A). A grading plan shall include:

A. An easily reproducible drawing at a scale of appropriate size to show location and details of all cuts and all fills including depth and finished slopes of all cuts and all fills.

B. A general vicinity map of the area and site plan of the project.

C. North arrow.

D. Dimensions and location of subject property boundary lines, location of the permit area boundary, existing and proposed roads, or driveways, easements, natural or man made bodies of water and drainages, critical areas, shorelines, and any existing or proposed structures, wells or septic systems on the site, and the distance between such features.
E. Bodies of water, critical areas, structures, wells and septic systems on adjacent property and lying within 50 feet of the subject grading activity boundary that could be affected by the proposed grading operations.

F. Location and dimensions of buffer areas to be maintained or established, and location and description of proposed erosion-control devices or structures.

G. Map drawn with contour intervals (5 foot or less) that adequately depict existing and proposed slope for the proposal.

H. Total quantities, in cubic yards, and type of cut and fill material, including on-site grading material, and imported material. Cross section drawings that include:
   1. Maximum depth of fill and maximum height of cuts.
   2. Existing and proposed buildings and their setbacks from cut or fill slopes.
   3. Existing grades extending a minimum of 20 feet beyond the scope of work.
   4. Finished grades of cuts and fills extending a minimum of 20 feet beyond the scope of work.
   5. Retaining walls and the adjacent grade at least 20 feet on either side of the wall(s).
   6. Grades of all existing cut and fill areas expressed as a ratio of horizontal to vertical slope.

I. The disposal site for excavated material. Off-site disposal may require a separate grading permit.

J. The location of proposed erosion and sedimentation control measures showing compliance with the requirements of SCC Section 24.02.090.

K. Detailed plans of all surface and subsurface drainage devices, walls, cribbing, dams, berms, settling ponds, or other water or erosion control devices to be utilized as a part of the proposed work.

L. Any recommendations included in an engineering geology or geotechnical assessment or report for grading or developing the property. If required, assessment and reports shall be completed in compliance with SCC Title 21A prior to issuance of a clearing and grading permit.

**Finding:**

Under Skamania County’s Critical Area Ordinance (Title 21A), the subject parcel is designated as a Class I Erosion Hazard Area due to the soil susceptibility to wind and water erosion and a portion of the subject parcel is designated as a Class II Landslide Hazard Area due to 20% slopes underlain with clay type soils. A geotechnical assessment report is required for the proposed project. The project is further required to have effective erosion control measures in place during all phases of the project.

A geotechnical report has been prepared for this project, but has not been reviewed by Skamania County at this time.

**Conclusion:**

The proposal states that an Engineer licensed in the State of Washington will prepare detailed clearing and grading plans that will be submitted to EFSEC for review and
approval prior to the start of construction. These plans will substantively comply with SCC Title 24 standards.

24.02.090 Grading Standards

Unless otherwise recommended in an approved soils engineering or engineering geology report, grading shall conform to the following standards. Erosion control measures may be installed as outlined in this title, unless otherwise recommended by a project engineer.

A. Appropriate erosion control measures shall be installed prior to any grading activity. All erosion control measures shall be maintained in place until vegetation is established for suitable erosion and sedimentation control. No sediment from grading operations shall be permitted to leave the site or enter any surface waters or wetlands. If the grading activity timeline includes winter months, then a “winter shutdown” standard for site erosion control will be provided by the applicant.

B. Sites shall have a finished grade that drains away from structural foundations for a minimum of 10 feet.

C. All sites shall be cleaned upon project completion, including installation of permanent native grass seeding, landscaping, or other organic means of erosion control.

D. Cuts or fills of five feet in depth or greater shall be set back from property lines by a minimum of 25 feet. This can be decreased with appropriate engineering. Setback dimensions shall be horizontal distances measured perpendicular to the site boundary.

E. The top of cut slopes shall not be made nearer to a permit area boundary line than one fifth of the vertical height of cut with a minimum of two feet and a maximum of 10 feet. The setback needs to be increased for any required interceptor drains.

F. The toe to fill slopes shall be made not nearer to the permit area boundary line than one-half the height of the slope with a minimum of two feet and a maximum of 20 feet.

G. The Director may approve alternate setbacks at the request of the applicant. In approving these alternate setbacks, the Director may require an investigation and recommendation by a qualified engineer or engineering geologist to demonstrate that the intent of this section has been satisfied.

H. Any proposed finished slope that is steeper than two horizontal to one vertical shall be engineered.

I. The ground surface shall be prepared to receive fill by removing all organic material, non-complying fill, and scarifying topsoil.

J. Solid Waste as defined in this chapter, and detrimental amounts of organic material shall not be used as fill materials.

K. Fill slopes shall not be constructed on natural or cut slopes steeper than two units horizontal in one unit vertical (50 percent slope) unless the permittee furnishes a geotechnical engineering or an engineering geology report or both, stating that the site has been investigated and giving an opinion that a cut at a steeper slope will be stable and not create a hazard to public or private property.

L. At the request of the applicant, the Director may approve the use of alternate grading standards. These approvals shall be based on sound
engineering practices and may require the submittal of additional
documentation, reports, or testing.

M. No grading shall obstruct or alter any existing natural drainage way,
stream, or any other natural body of water.

N. No grading shall alter or increase surface drainage onto any adjacent
properties.

Finding:
The proposal states that an Engineer licensed in the State of Washington will prepare
detailed clearing and grading plans that will be submitted to EFSEC for review and
approval prior to the start of construction.

Conclusion:
These plans will substantively comply with SCC Title 24 standards.

24.02.100 Grading Inspection
Grading projects for which a permit is required shall be subject to inspection by
the Director. A licensed Washington State professional engineer shall provide
professional inspections of grading operations if engineering is required
elsewhere in this title. An inspection schedule shall be established for each
project prior to permit issuance based on the following:

A. A civil engineer shall provide professional inspections within such
engineer’s area of technical specialty, which shall consist of observation
and review as to the establishment of line, grade and surface drainage of
the development area. If revised plans are required during the course of
the work, they shall be prepared by the civil engineer.

B. A geotechnical engineer and/or engineering geologist shall provide
professional inspection within such engineer’s area of technical specialty,
which shall include observation during grading and testing for required
compaction. The engineer shall provide sufficient observation during the
preparation of the natural ground and placement in accordance with the
conditions of the approved plan and the appropriate requirements of this
title. He or she shall also provide professional inspection of any
excavation to determine if conditions encountered are in conformance
with the approved report or plan. Revised recommendations relating to
conditions differing from the approved engineering geology or
geotechnical reports shall be submitted to the permittee, the Department,
and the civil engineer.

C. The permittee shall be responsible for the work being performed in
accordance with the approved plans and specifications and in
conformance with the provisions of the title. When approved by the
Director, the permittee may engage consultants, if required, to provide
professional inspections on a timely basis. The permittee shall act as a
coordinator between the consultants, the contractor and the Department.
In the event of changing conditions, the permittee shall be responsible
for informing the Department of such change and shall provide revised
plans for approval.

D. The Department may inspect the project in various stages of work.

E. If, in the course of fulfilling their respective duties under this title, the civil
engineer, geotechnical engineer, or engineering geologist finds that the
work is not being done in conformance with this title or approved grading plans, the discrepancies shall be reported in writing within three working days to the permittee and to the Department.

F. If the civil engineer, geotechnical engineer, or engineering geologist of record is changed during grading, the work shall be stopped until the replacement has agreed in writing to accept the responsibility within the area of technical competence for approval upon completion of the work. It shall be the duty of the permittee to notify the Department in writing of such a change prior to the recommencement of such grading.

Finding:
The proposal states that an Engineer licensed in the State of Washington will prepare detailed clearing and grading plans that will be submitted to EFSEC for review and approval prior to the start of construction.

Conclusion:
These plans will substantively comply with SCC Title 24 standards.

Re: Area of Potential Effects- Concurrence and Comments

Dear Mr. La Spina:

We have reviewed the material you forwarded to our office that describes the area of potential effect (APE) for the Whistling Ridge Wind Energy Project in Skamania County. We concur with the definition of the APE. We look forward to receiving any correspondence or comments from the concerned Tribes or other parties and the cultural resources survey report when it is available.

These comments are based on the information available at the time of this review and on behalf of the State Historic Preservation Officer. Thank you for your consultation. If you have any questions, please feel free to contact me.

Sincerely,

Gretchen Kaehler
Assistant State Archaeologist

RE: Proposed Whistling Ridge Energy Project, Skamania County, Washington  
Northwestern Lake Quad, T3N, R10E, Sections 7 and 18

Dear Dr. Whitlam:

Bonneville Power Administration (BPA) is proposing to interconnect the Whistling Ridge Energy Project in Skamania County, WA. This proposed interconnection would connect up to 70 MW from the proposed wind facility consisting of up to approximately 50, 1.2- to 2.5-MW wind turbines. Pursuant to its responsibilities under Section 106 of the National Historic Preservation Act and 36 CFR 800, BPA has determined that the proposed action is a federal undertaking that has the potential to cause effects on historic properties and seeks to initiate consultation with your agency – the Washington State Office of Archeology and Historic Preservation. BPA also initiated consultation with The Confederated Tribes of the Umatilla Indian Reservation, The Confederated Tribes of the Warm Springs Reservation of Oregon, The Nez Perce Tribe of Idaho, and The Confederated Tribes and Bands of the Yakama Reservation, and The Columbia River Inter-Tribal Fish Commission (CRITFC) pursuant to 36 CFR 800.4(a)(4).

The Area of Potential Effect (APE) for the proposed project has been determined and is located on the attached APE Map. Additionally, a project overview map is also being included to depict the total project area of the proposed wind facility and that of BPA’s proposed action. The project will be located in T3N, R10E, Sections 7 and 18 (Northwestern Lake Quadrangle). The APE is briefly described below.

The proposed project would include the construction of a new BPA substation located within the project area which would assist in the transfer of the power generated from the project onto BPA’s North Bonneville-Midway 230-kV transmission line. The BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there will be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work associated with substations. There will be a graveled access road to the site as well
as access roads running underneath the additional transmission line structures that will be built. This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.

This interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection.

Upon receipt of comments from your office concerning the proposed project and APE, BPA will determine the appropriate action for the identification and protection of historic properties within the APE. This may include tribal input for Traditional Cultural Properties, if indicated as an area of concern for any of the contacted tribes. A field survey covering the entire APE shown on the enclosed map is planned to be conducted. Furthermore, the identification, evaluation, and mitigation activities will be conducted by an individual meeting the Secretary of the Interior’ standards. Following the background research and field survey, a technical report will be prepared and submitted to your office and to any affected tribes.

In this initiation of consultation, BPA seeks your concurrence on the proposed undertaking and APE discussed above. We also seek any information that you might have on known archaeological resources in the project area. Based on the interest of time, we anticipate your immediate response to this consultation.

If you have any questions or concerns, please do not hesitate to contact me at (503) 230-4145 or email me at ammontano@bpa.gov.

Sincerely,

/s/ Andrew M. Montaño, Aug. 2, 2010

Re: Whistling Ridge Substation Project
Log No.: 080910-26-BPA

Dear Mr. Montano;

Thank you for contacting our department. We have reviewed the materials you provided for the Area of Potential Effect (APE) for the proposed Whistling Ridge Energy Project Substation Project near Underwood, Skamania, County, Washington.

We concur with your determination of the Area of Potential Effect (APE) as described and presented in your figures and text.

We would also appreciate receiving any correspondence or comments from concerned tribes or other parties that you receive as you consult under the requirements of 36CFR800.4(a)(4).

These comments are based on the information available at the time of this review and on behalf of the State Historic Preservation Officer in compliance with the Section 106 of the National Historic Preservation Act, as amended, and its implementing regulations 36CFR800.4. Should additional information become available, our assessment may be revised. Thank you for the opportunity to comment and we look forward to receiving the results of the professional archaeological survey report, your consultation efforts, and your Determination of Effect.

Sincerely,

In reply refer to: KEC-4

William Iyall, Chairman
Cowlitz Indian Tribe
PO Box 2547
Longview, WA 98632

RE: Proposed Whistling Ridge Energy Project, Skamania County, Washington
Northwestern Lake Quad, T3N, R10E, Sections 7 and 18

Dear Mr. Iyall:

Bonneville Power Administration (BPA) is proposing to interconnect the Whistling Ridge Energy Project in Skamania County, WA. This proposed interconnection would connect up to 70 MW from the proposed wind facility consisting of up to approximately 50, 1.2- to 2.5-MW wind turbines. Pursuant to its responsibilities under Section 106 of the National Historic Preservation Act and 36 CFR 800, BPA has determined that the proposed action is a federal undertaking that has the potential to cause effects on historic properties and seeks to initiate consultation with your Tribe. BPA also initiated consultation with the Washington State Office of Archeology and Historic Preservation, as well as The Confederated Tribes of the Umatilla Indian Reservation, The Confederated Tribes of the Warm Springs Reservation of Oregon, The Confederated Tribes and Bands of the Yakama Reservation, The Nez Perce Tribe of Idaho, and The Columbia River Inter-Tribal Fish Commission (CRITFC) pursuant to 36 CFR 800.4(a)(4).

The Area of Potential Effect (APE) for the proposed project has been determined and is located on the attached APE Map. Additionally, a project overview map is also being included to depict the total project area of the proposed wind facility and that of BPA’s proposed action. The project will be located in T3N, R10E, Sections 7 and 18 (Northwestern Lake Quadrangle). The APE is briefly described below.

The proposed project would include the construction of a new BPA substation located within the project area which would assist in the transfer of the power generated from the project onto BPA’s North Bonneville-Midway 230-kV transmission line. The BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there will be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work associated with substations. There will be a graveled access road to the site as well as access roads running underneath the additional transmission line structures that will be built.
This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.

This interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection.

Upon receipt of comments from your office concerning the proposed project and APE, BPA will determine the appropriate action for the identification and protection of historic properties within the APE. This may include tribal input for Traditional Cultural Properties, if indicated as an area of concern for yours or any of the other contacted tribes. A field survey covering the entire APE shown on the enclosed map is planned to be conducted. Furthermore, the identification, evaluation, and mitigation activities will be conducted by an individual meeting the Secretary of the Interior’s standards. Following the background research and field survey, a technical report will be prepared and submitted to your office and to any affected tribes.

In this initiation of consultation, BPA seeks your concurrence on the proposed undertaking and APE discussed above. We also seek any information that you might have on known archaeological resources in the project area. Based on the interest of time, we anticipate your immediate response to this consultation.

If you have any questions or concerns, please do not hesitate to contact me at (503) 230-4145 or email me at ammontano@bpa.gov.

Sincerely,

RE: Proposed Whistling Ridge Energy Project, Skamania County, Washington
Northwestern Lake Quad, T3N, R10E, Sections 7 and 18

Dear Mr. Brunoe:

Bonneville Power Administration (BPA) is proposing to interconnect the Whistling Ridge Energy Project in Skamania County, WA. This proposed interconnection would connect up to 70 MW from the proposed wind facility consisting of up to approximately 50, 1.2- to 2.5-MW wind turbines. Pursuant to its responsibilities under Section 106 of the National Historic Preservation Act and 36 CFR 800, BPA has determined that the proposed action is a federal undertaking that has the potential to cause effects on historic properties and seeks to initiate consultation with your Tribe. BPA also initiated consultation with the Washington State Office of Archeology and Historic Preservation, as well as The Confederated Tribes of the Umatilla Indian Reservation, The Nez Perce Tribe of Idaho, The Confederated Tribes and Bands of the Yakama Reservation, and The Columbia River Inter-Tribal Fish Commission (CRITFC) pursuant to 36 CFR 800.4(a)(4).

The Area of Potential Effect (APE) for the proposed project has been determined and is located on the attached APE Map. Additionally, a project overview map is also being included to depict the total project area of the proposed wind facility and that of BPA’s proposed action. The project will be located in T3N, R10E, Sections 7 and 18 (Northwestern Lake Quadrangle). The APE is briefly described below.

The proposed project would include the construction of a new BPA substation located within the project area which would assist in the transfer of the power generated from the project onto BPA’s North Bonneville-Midway 230-kV transmission line. The BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there will be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work associated with substations. There will be a graveled access road to the site as well as access roads running underneath the additional transmission line structures that will be built.
This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.

This interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection.

Upon receipt of comments from your office concerning the proposed project and APE, BPA will determine the appropriate action for the identification and protection of historic properties within the APE. This may include tribal input for Traditional Cultural Properties, if indicated as an area of concern for yours or any of the other contacted tribes. A field survey covering the entire APE shown on the enclosed map is planned to be conducted. Furthermore, the identification, evaluation, and mitigation activities will be conducted by an individual meeting the Secretary of the Interior’s standards. Following the background research and field survey, a technical report will be prepared and submitted to your office and to any affected tribes.

In this initiation of consultation, BPA seeks your concurrence on the proposed undertaking and APE discussed above. We also seek any information that you might have on known archaeological resources in the project area. Based on the interest of time, we anticipate your immediate response to this consultation.

If you have any questions or concerns, please do not hesitate to contact me at (503) 230-4145 or email me at ammontano@bpa.gov.

Keith Baird
Cultural Resources Director
Nez Perce Tribe of Idaho
P.O. Box 305
Lapwai, ID 83540

RE: Proposed Whistling Ridge Energy Project, Skamania County, Washington
Northwestern Lake Quad, T3N, R10E, Sections 7 and 18

Dear Mr. Baird:

Bonneville Power Administration (BPA) is proposing to interconnect the Whistling Ridge Energy Project in Skamania County, WA. This proposed interconnection would connect up to 70 MW from the proposed wind facility consisting of up to approximately 50, 1.2- to 2.5-MW wind turbines. Pursuant to its responsibilities under Section 106 of the National Historic Preservation Act and 36 CFR 800, BPA has determined that the proposed action is a federal undertaking that has the potential to cause effects on historic properties and seeks to initiate consultation with your Tribe. BPA also initiated consultation with the Washington State Office of Archeology and Historic Preservation, as well as The Confederated Tribes of the Umatilla Indian Reservation, The Confederated Tribes of the Warm Springs Reservation of Oregon, The Confederated Tribes and Bands of the Yakama Reservation, and The Columbia River Inter-Tribal Fish Commission (CRITFC) pursuant to 36 CFR 800.4(a)(4).

The Area of Potential Effect (APE) for the proposed project has been determined and is located on the attached APE Map. Additionally, a project overview map is also being included to depict the total project area of the proposed wind facility and that of BPA’s proposed action. The project will be located in T3N, R10E, Sections 7 and 18 (Northwestern Lake Quadrangle). The APE is briefly described below.

The proposed project would include the construction of a new BPA substation located within the project area which would assist in the transfer of the power generated from the project onto BPA’s North Bonneville-Midway 230-kV transmission line. The BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there will be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work associated with substations. There will be a graveled access road to the site as well as access roads running underneath the additional transmission line structures that will be built.
This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.

This interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection.

Upon receipt of comments from your office concerning the proposed project and APE, BPA will determine the appropriate action for the identification and protection of historic properties within the APE. This may include tribal input for Traditional Cultural Properties, if indicated as an area of concern for yours or any of the other contacted tribes. A field survey covering the entire APE shown on the enclosed map is planned to be conducted. Furthermore, the identification, evaluation, and mitigation activities will be conducted by an individual meeting the Secretary of the Interior’ standards. Following the background research and field survey, a technical report will be prepared and submitted to your office and to any affected tribes.

In this initiation of consultation, BPA seeks your concurrence on the proposed undertaking and APE discussed above. We also seek any information that you might have on known archaeological resources in the project area. Based on the interest of time, we anticipate your immediate response to this consultation.

If you have any questions or concerns, please do not hesitate to contact me at (503) 230-4145 or email me at ammontano@bpa.gov.

Sincerely,

Andrew M. Montano  
Environmental Project Manager  
Bonneville Power Administration  
P.O. Box 14428  
Portland, Oregon 97293-4428

Dear Mr. Posner and Mr. Montano,

We have reviewed the recent Draft Environmental Impact Statement (DEIS) complied for the Whistling Ridge Energy Facility. In doing so, we noted under section 3.10.2.2 no mention has been made of the finding of the Yakama Nation Cultural Resources Program study which resulted in the findings of Traditional Cultural Property within the proposed wind project lands. The DEIS states that:

"A field investigation by Yakama Nation cultural resources specialists occurred in December 2009. The Yakama Nation's findings, currently in preparation, will supplement the information contained in this EIS."

However, the results of the field investigation were reported to SDS Lumber and the Department of Archaeology and Historic Preservation in December of 2009, shortly after the site visit was completed. We, therefore, are taking this opportunity to resubmit this report to the Energy Facility Siting Evaluation Council (EFSEC) and the Bonneville Power Administration (BPA). It is our directive that this report be included in the Final Environmental Impact Statement as a portion of the consultation responsibilities held by BPA and EFSEC.

Sincerely,

Ruth Jim  
Chairman, Yakama Nation Roads, Irrigation, and Lands Committee

Mr. Harry Smiskin, Chairman
Yakama Nation Tribal Council
Confederated Tribes and Bands of the Yakama Nation
P.O. Box 151
Toppenish, WA 98948

Dear Mr. Smiskin:

The Bonneville Power Administration (BPA) is nearing its deadline for comments regarding the Draft Environmental Impact Statement (DEIS) issued for the Whistling Ridge Energy Project. I would be interested in hearing from the Confederated Tribes and Bands of the Yakama Nation regarding your input to this project. I hope that you have had sufficient time to look at our DEIS and welcome any suggestions you may have. Additionally, I wanted to let you know that BPA has received concurrence to the Area of Potential Effects from the Washington State Historic Preservation Office regarding the location where our interconnection would take place if this proposed project were to move forward.

I welcome any questions and/or comments that you may have regarding this project. Please feel free to contact me directly at (503) 230-4145 or at ammontano@bpa.gov at any time.

Thank you for your interest in this project.

Sincerely,

/s/Andrew Montano 08-30-2010

RE: Proposed Whistling Ridge Energy Project, Skamania County, Washington
Northwestern Lake Quad, T3N, R10E, Sections 7 and 18

Dear Ms. Valdez:

Bonneville Power Administration (BPA) is proposing to interconnect the Whistling Ridge Energy Project in Skamania County, WA. This proposed interconnection would connect up to 70 MW from the proposed wind facility consisting of up to approximately 50, 1.2- to 2.5-MW wind turbines. Pursuant to its responsibilities under Section 106 of the National Historic Preservation Act and 36 CFR 800, BPA has determined that the proposed action is a federal undertaking that has the potential to cause effects on historic properties and seeks to initiate consultation with your Tribe. BPA also initiated consultation with the Washington State Office of Archeology and Historic Preservation, as well as The Confederated Tribes of the Umatilla Indian Reservation, The Confederated Tribes of the Warm Springs Reservation of Oregon, The Nez Perce Tribe of Idaho, and The Columbia River Inter-Tribal Fish Commission (CRITFC) pursuant to 36 CFR 800.4(a)(4).

The Area of Potential Effect (APE) for the proposed project has been determined and is located on the attached APE Map. Additionally, a project overview map is also being included to depict the total project area of the proposed wind facility and that of BPA’s proposed action. The project will be located in T3N, R10E, Sections 7 and 18 (Northwestern Lake Quadrangle). The APE is briefly described below.

The proposed project would include the construction of a new BPA substation located within the project area which would assist in the transfer of the power generated from the project onto BPA’s North Bonneville-Midway 230-kV transmission line. The BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there will be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work associated with substations. There will be a graveled access road to the site as well as access roads running underneath the additional transmission line structures that will be built.
This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.

This interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection.

Upon receipt of comments from your office concerning the proposed project and APE, BPA will determine the appropriate action for the identification and protection of historic properties within the APE. This may include tribal input for Traditional Cultural Properties, if indicated as an area of concern for yours or any of the other contacted tribes. A field survey covering the entire APE shown on the enclosed map is planned to be conducted. Furthermore, the identification, evaluation, and mitigation activities will be conducted by an individual meeting the Secretary of the Interior’s standards. Following the background research and field survey, a technical report will be prepared and submitted to your office and to any affected tribes.

In this initiation of consultation, BPA seeks your concurrence on the proposed undertaking and APE discussed above. We also seek any information that you might have on known archaeological resources in the project area. Based on the interest of time, we anticipate your immediate response to this consultation.

If you have any questions or concerns, please do not hesitate to contact me at (503) 230-4145 or email me at ammontano@bpa.gov.

Sincerely,

/s/ Andrew M. Montaño, Aug. 2, 2010

Enclosures:
APE Map
Project Overview Map
RE: Proposed Whistling Ridge Energy Project Skamania County, Washington

Thank you for contacting Yakama Nation regarding the Proposed Whistling Ridge Energy Project. The Project is located within the Ceded Lands of the Yakama Nation, the legal rights to which were established by the Treaty of 1855, between the Yakama Nation and the United States Government. The Treaty set forth that the Yakama Nation shall retain rights to resources upon these lands and, therefore, it is with the assistance and backing of the United States Federal Government that Yakama Nation claims authority to protect traditional resources.

Yakama Nation does not agree with the APE defined by the Bonneville Power Administration (BPA). The Whistling Ridge Energy Project Draft Environmental Impact Statement (DEIS) implies that the Whistling Ridge project is dependent upon a BPA interconnection. Page 1-6 of the DEIS states,

"... it is critical to locate projects in areas where transmission lines currently exit. The Applicant thus needs to locate near exiting high-voltage transmission, such as the PCRTS."

Since the Whistling Ridge Project cannot proceed without BPA interconnection, we believe this project should be reviewed under NEPA, BPA involvement creating a federal nexus. Therefore, the appropriate APE for the BPA interconnection should include the entire Whistling Ridge Project area.

Yakama Nation CRP has provided both EFSEC and BPA information regarding the existence of Traditional Cultural Properties within the Whistling Ridge Project. We trust that prior to interconnection with this facility, BPA will ensure that Yakama Nation’s concerns regarding the DEIS are addressed and that consultation regarding the identified cultural resources is completed.

If you have any questions, please feel free to contact me at 509-865-5121 x4737, or Yakama Nation Archaeologist, Jessica Lally at x4766.

Sincerely,

George Colby
Attorney for the Yakama Nation Executive Committee

RE:  Proposed Whistling Ridge Energy Project, Skamania County, Washington
     Northwestern Lake Quad, T3N, R10E, Sections 7 and 18
     Log No.: 080910-26-BPA

Dear Mr. Whitlam:

Bonneville Power Administration (BPA) is proposing to interconnect the Whistling Ridge Energy Project in Skamania County, WA. This proposed interconnection would connect up to 70 MW from the proposed wind facility consisting of up to approximately 50, 1.2- to 2.5-MW wind turbines. Pursuant to its responsibilities under Section 106 of the National Historic Preservation Act and 36 CFR 800, BPA has determined that the proposed interconnection is a federal undertaking that has the potential to cause effects on historic properties and initiated consultation with your agency – the Washington State Office of Archeology and Historic Preservation. BPA also initiated consultation with The Confederated Tribes of the Umatilla Indian Reservation, The Cowlitz Indian Tribe, The Confederated Tribes of the Warm Springs Reservation of Oregon, The Nez Perce Tribe of Idaho, The Confederated Tribes and Bands of the Yakama Reservation, and The Columbia River Inter-Tribal Fish Commission pursuant to 36 CFR 800.4(a)(4).

As acknowledged by your office on August 9, 2010, the Area of Potential Effects for the proposed interconnection will be limited to the following locations: T3N, R10E, Section 7 and Section 18 (Northwestern Lake Quadrangle). The proposed interconnection is described below.

The proposed interconnection would include the construction of a new BPA substation located within the wind development’s project area, which would assist in the transfer of the power generated from the project onto BPA’s North Bonneville-Midway 230-kV transmission line. The BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there will be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work associated with substations. There will be a graveled access road to the site as well as access roads running underneath the additional
transmission line structures that will be built. This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.

This proposed interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection.

A cultural survey was performed at this location on November 9-11th, 2009, and the survey report is being included with this letter. On September 10, 2010, BPA was contacted by The Confederated Tribes and Bands of the Yakama Reservation in which the Tribe expressed that the APE should include the proposed wind development (which encompassed some culturally-sensitive areas) in addition to the proposed interconnection. BPA met with representatives of the Tribe on May 2nd, 2011, to discuss the Tribe’s request for an expanded APE. BPA discussed with the Tribe that BPA has no jurisdiction over siting of wind development facilities, a matter left to Washington EFSEC, and that BPA’s APE is limited to the proposed interconnection.

After reviewing the findings of the cultural survey report, BPA finds that the nature and the location of this proposed interconnection poses a very minimal potential to cause effects to historic properties. Therefore, it is the opinion of the BPA Archaeologist that the undertaking should result in no historic properties affected. In the unlikely event that archaeological materials are encountered during the implementation of this interconnection, an archaeologist will immediately be notified and work halted in the vicinity of the finds until they can be inspected and assessed. Additionally, if any findings did occur, your office and the appropriate Tribes will be notified of any future findings.

If you have any questions or concerns, please do not hesitate to contact me at (503) 230-4145 or by email at ammontano@bpa.gov. The BPA Archeologist, Nicole Brannan, can also be contacted at (503) 230-7579 or at nfbrannan@bpa.gov.

Sincerely,

/s/ Andrew M. Montaño, June 2, 2011

Log No.: 080910-26-BPA

Dear Mr. Montano:

Thank you for contacting our department. We have reviewed the professional archaeological survey report you provided for the proposed Whistling Ridge Energy Substation Project, Skamania County, Washington.

We concur with your determination of No Historic Properties Affected.

We would appreciate receiving any correspondence or comments from concerned tribes or other parties that you receive as you consult under the requirements of 36CFR800.4(a)(4).

These comments are based on the information available at the time of this review and on the behalf of the State Historic Preservation Officer in conformance with Section 106 of the National Historic Preservation Act and its implementing regulations 36CFR800. Should additional information become available, our assessment may be revised. Thank you for the opportunity to comment and a copy of these comments should be included in subsequent environmental documents.

Sincerely,

RE: Proposed Whistling Ridge Energy Project, Skamania County, Washington
Northwestern Lake Quad, T3N, R10E, Sections 7 and 18

Dear Mr. Burlingame:

Bonneville Power Administration (BPA) is proposing to interconnect the Whistling Ridge Energy Project in Skamania County, WA. This proposed interconnection would connect up to 70 MW from the proposed wind facility consisting of up to approximately 50, 1.2- to 2.5-MW wind turbines. Pursuant to its responsibilities under Section 106 of the National Historic Preservation Act and 36 CFR 800, BPA has determined that the proposed action is a federal undertaking that has the potential to cause effects on historic properties and seeks to initiate consultation with your Tribe. BPA also initiated consultation with the Washington State Department of Archeology and Historic Preservation, as well as The Confederated Tribes of the Umatilla Indian Reservation, The Confederated Tribes of the Warm Springs Reservation of Oregon, The Confederated Tribes and Bands of the Yakama Reservation, The Nez Perce Tribe of Idaho, and The Columbia River Inter-Tribal Fish Commission (CRITFC) pursuant to 36 CFR 800.4(a)(4).

The Area of Potential Effects will be limited to the following locations: T3N, R10E, Section 7 and Section 18 (Northwestern Lake Quadrangle). The APE is described below.

The proposed Project would include the construction of a new BPA substation located within the project area which would assist in the transfer of the power generated from the project onto BPA’s North Bonneville-Midway 230-kV transmission line (an interconnection). The BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there will be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work associated with substations. There will be a graveled access road to the site as well as access roads running underneath the additional transmission line structures that will be built. This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.
This interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection.

A cultural survey was performed at this location on November 9-11th, 2009, and the survey report is being included with this letter. After reviewing the findings of the cultural survey report, the undertaking, and the APE, BPA feels that the nature and the location of this proposed interconnections poses a very minimal potential to cause effects to historic properties. Therefore, it is the opinion of the BPA Archaeologist that the undertaking should result in no historic properties affected. In the unlikely event that archaeological materials are encountered during the implementation of this project, an archaeologist will immediately be notified and work halted in the vicinity of the finds until they can be inspected and assessed. Additionally, if any findings did occur, your office and any other interested parties will be notified of any future findings. If you have any questions or concerns, please do not hesitate to contact me at (503) 230-4145 or by email at ammontano@bpa.gov. The BPA Archeologist, Nicole Brannan, can also be contacted at (503) 230-7579 or at nibrannan@bpa.gov.

RE:  Proposed Whistling Ridge Energy Project, Skamania County, Washington  
Northwestern Lake Quad, T3N, R10E, Sections 7 and 18

Dear Mr. Brunoe:

Bonneville Power Administration (BPA) is proposing to interconnect the Whistling Ridge Energy Project in Skamania County, WA. This proposed interconnection would connect up to 70 MW from the proposed wind facility consisting of up to approximately 50, 1.2- to 2.5-MW wind turbines. Pursuant to its responsibilities under Section 106 of the National Historic Preservation Act and 36 CFR 800, BPA has determined that the proposed action is a federal undertaking that has the potential to cause effects on historic properties and seeks to initiate consultation with your Tribe. BPA also initiated consultation with the Washington State Department of Archeology and Historic Preservation, as well as The Columbia River Inter-Tribal Fish Commission (CRITFC), The Confederated Tribes of the Umatilla Indian Reservation, The Confederated Tribes and Bands of the Yakama Reservation, The Nez Perce Tribe of Idaho, and The Cowlitz Indian Tribe pursuant to 36 CFR 800.4(a)(4).

The Area of Potential Effects will be limited to the following locations:  T3N, R10E, Section 7 and Section 18 (Northwestern Lake Quadrangle). The APE is described below.

The proposed Project would include the construction of a new BPA substation located within the project area which would assist in the transfer of the power generated from the project onto BPA’s North Bonneville-Midway 230-kV transmission line (an interconnection). The BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there will be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work associated with substations. There will be a graveled access road to the site as well as access roads running underneath the additional transmission line structures that will be built. This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.
This interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection.

A cultural survey was performed at this location on November 9-11th, 2009, and the survey report is being included with this letter. After reviewing the findings of the cultural survey report, the undertaking, and the APE, BPA feels that the nature and the location of this proposed interconnection poses a very minimal potential to cause effects to historic properties. Therefore, it is the opinion of the BPA Archaeologist that the undertaking should result in no historic properties affected. In the unlikely event that archaeological materials are encountered during the implementation of this project, an archaeologist will immediately be notified and work halted in the vicinity of the finds until they can be inspected and assessed. Additionally, if any findings did occur, your office and any other interested parties will be notified of any future findings. If you have any questions or concerns, please do not hesitate to contact me at (503) 230-4145 or by email at ammontano@bpa.gov. The BPA Archeologist, Nicole Brannan, can also be contacted at (503) 230-7579 or at nfbrannan@bpa.gov.

Sincerely,

/s/ Andrew M. Montaño, June 2, 2011

Lapwai, ID 83540

RE: Proposed Whistling Ridge Energy Project, Skamania County, Washington
Northwestern Lake Quad, T3N, R10E, Sections 7 and 18

Dear Mr. Baird:

Bonneville Power Administration (BPA) is proposing to interconnect the Whistling Ridge Energy Project in Skamania County, WA. This proposed interconnection would connect up to 70 MW from the proposed wind facility consisting of up to approximately 50, 1.2- to 2.5-MW wind turbines. Pursuant to its responsibilities under Section 106 of the National Historic Preservation Act and 36 CFR 800, BPA has determined that the proposed action is a federal undertaking that has the potential to cause effects on historic properties and seeks to initiate consultation with your Tribe. BPA also initiated consultation with the Washington State Department of Archeology and Historic Preservation, as well as The Columbia River Inter-Tribal Fish Commission (CRITFC), The Confederated Tribes of the Umatilla Indian Reservation, The Confederated Tribes and Bands of the Yakama Reservation, The Confederated Tribes of the Warm Springs Reservation of Oregon, and The Cowlitz Indian Tribe pursuant to 36 CFR 800.4(a)(4).

The Area of Potential Effects will be limited to the following locations: T3N, R10E, Section 7 and Section 18 (Northwestern Lake Quadrangle). The APE is described below.

The proposed Project would include the construction of a new BPA substation located within the project area which would assist in the transfer of the power generated from the project onto BPA’s North Bonneville-Midway 230-kV transmission line (an interconnection). The BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there will be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work associated with substations. There will be a graveled access road to the site as well as access roads running underneath the additional transmission line structures that will be built. This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.
This interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection.

A cultural survey was performed at this location on November 9-11th, 2009, and the survey report is being included with this letter. After reviewing the findings of the cultural survey report, the undertaking, and the APE, BPA feels that the nature and the location of this proposed interconnection poses a very minimal potential to cause effects to historic properties. Therefore, it is the opinion of the BPA Archaeologist that the undertaking should result in no historic properties affected. In the unlikely event that archaeological materials are encountered during the implementation of this project, an archaeologist will immediately be notified and work halted in the vicinity of the finds until they can be inspected and assessed. Additionally, if any findings did occur, your office and any other interested parties will be notified of any future findings. If you have any questions or concerns, please do not hesitate to contact me at (503) 230-4145 or by email at ammontano@bpa.gov. The BPA Archeologist, Nicole Brannan, can also be contacted at (503) 230-7579 or at nfbrannan@bpa.gov.

Sincerely,

/s/ Andrew M. Montaño, June 2, 2011

June 2, 2011

In reply refer to: KEC-4

Ms. V. Kate Valdez, THPO
Confederated Tribes and Bands of the Yakama Reservation
P.O. Box 151
Toppenish, WA 98948

RE: Proposed Whistling Ridge Energy Project, Skamania County, Washington
Northwestern Lake Quad, T3N, R10E, Sections 7 and 18

Dear Ms. Valdez:

Bonneville Power Administration (BPA) is proposing to interconnect the Whistling Ridge Energy Project in Skamania County, WA. This proposed interconnection would connect up to 70 MW from the proposed wind facility consisting of up to approximately 50, 1.2- to 2.5-MW wind turbines. Pursuant to its responsibilities under Section 106 of the National Historic Preservation Act and 36 CFR 800, BPA has determined that the proposed action is a federal undertaking that has the potential to cause effects on historic properties and seeks to initiate consultation with your Tribe. BPA also initiated consultation with the Washington State Department of Archeology and Historic Preservation, as well as The Columbia River Inter-Tribal Fish Commission (CRITFC), The Confederated Tribes of the Umatilla Indian Reservation, The Nez Perce Tribe of Idaho, The Confederated Tribes of the Warm Springs Reservation of Oregon, and The Cowlitz Indian Tribe pursuant to 36 CFR 800.4(a)(4).

The Area of Potential Effects for the proposed interconnection will be limited to the following locations: T3N, R10E, Section 7 and Section 18 (Northwestern Lake Quadrangle). The proposed interconnection is described below.

The proposed interconnection would include the construction of a new BPA substation located within the wind development’s project area which would assist in the transfer of the power generated from the project onto BPA’s North Bonneville-Midway 230-kV transmission line. The BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there will be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work associated with substations. There will be a graveled access road to the site as well as access roads running underneath the additional transmission line structures that will be built. This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.

This proposed interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require
several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection.

A cultural survey was performed at this location on November 9-11th, 2009, and the survey report is being included with this letter. By letter dated May 27th, 2010, the Tribe submitted its Yakama Nation Cultural Resource Review and Consultation for the Whistling Ridge Energy Project. This report identified culturally-sensitive areas within the wind development’s project area. By letter dated September 10, 2010, the Tribe expressed that the APE should include the proposed wind development (which encompassed the culturally-sensitive areas) in addition to the proposed interconnection. BPA met with representatives of the Tribe on May 2nd, 2011, to discuss the Tribe’s request for an expanded APE. BPA discussed with the Tribe that BPA has no jurisdiction over siting of wind development’s facilities, a matter left to Washington EFSEC, and that BPA’s APE is limited to the proposed interconnection. BPA and the Tribe also discussed the Tribe’s concerns about the culturally-sensitive areas in the wind development project area. We discussed BPA’s lack of jurisdiction of siting authority in relation to placement of turbine strings. BPA agreed that it would disclose the Tribal concerns about these culturally-sensitive areas in our Final EIS, but BPA is unable to address these concerns as a matter of Section 106 consultation under the NHPA.

BPA recognizes that there are culturally-sensitive areas within the wind development’s project area. However, for purposes of the proposed interconnection APE, based on all of the survey results, it is the opinion of the BPA Archaeologist that the proposed interconnection should result in no historic properties affected. In the unlikely event that archaeological materials are encountered during the implementation of this proposed interconnection, an archaeologist will immediately be notified and work halted in the vicinity of the finds until they can be inspected and assessed. Additionally, if any findings did occur, your office and any other interested parties will be notified of any future findings.

If you have any questions or concerns, please do not hesitate to contact me at (503) 230-4145 or by email at ammontano@bpa.gov. The BPA Archaeologist, Nicole Brannan, can also be contacted at (503) 230-7579 or at nfbrannan@bpa.gov.

Sincerely,

/s/ Andrew M. Montaño, June 2, 2011

Appendix E-3
BPA Section 7(a) Consultation Letters
June 8, 2010

In reply refer to: KEC-4

Mr. James Michaels
U.S. Fish and Wildlife Service
Washington Fish and Wildlife Office
510 Desmond Drive SE
Lacey, WA 98503

Dear Mr. Michaels:

Bonneville Power Administration (BPA) is proposing to interconnect up to 70 megawatts (MW) of new wind energy from the proposed Whistling Ridge Energy Project onto the North Bonneville-Midway 230-kilovolt transmission line. This interconnection request was made by the SDS Lumber Company in Bingen, Washington, and interconnection would take place approximately five miles west of BPA’s Underwood Substation in Skamania County, Washington. Subsequently, SDS Lumber Company created a new limited liability company called Whistling Ridge Energy LLC (WRE), which submitted an application with the State of Washington’s Energy Facility Site Evaluation Council (EFSEC) for site certification on this wind facility project. WRE would finance, develop, own and operate the proposed wind project. The proposed wind facility would consist of up to approximately 50, 1.2- to 2.5-MW wind turbines up to 426 feet tall, as well as infrastructure such as newly-constructed and improved roads, transformers, underground collector lines, a substation, and an operations and maintenance facility.

The proposed Whistling Ridge Energy Project would be located on private land located approximately 7 miles northwest of the City of White Salmon in Skamania County, Washington (See Figure 1). The Project would be located on commercial forestland in an unincorporated area of Skamania County, outside of the Columbia Gorge National Scenic Area. The Project Area encompasses approximately 1,152 acres in Sections 5, 6, 7, 8, and 18 of Township 3 North, Range 10 East, and in Section 13 of Township 3 North, Range 9 East.

To inform its decision on whether to allow the proposed interconnection, BPA is preparing a joint Environmental Impact Statement with the EFSEC as required under the National Environmental Policy Act (NEPA) of 1969, as amended. A species list for Skamania County, Washington, was obtained from the U.S. Fish and Wildlife Service (USFWS) web site (http://www.fws.gov/wafwo/speciesmap/SKAMAN.html) on December 30, 2009. Northern spotted owl (Strix occidentalis caurina) is listed as threatened, and designated critical habitat exists for this species within Skamania County. None of these species have been known to occur in the vicinity of the project site and there have been extensive surveys conducted as part of the
project permitting (See *Whistling Ridge Energy Project Draft Environmental Impact Statement May 2010, Chapter 3, [http://www.bpa.gov/go/whistling](http://www.bpa.gov/go/whistling)). BPA is seeking to initiate informal consultation under Section 7 of the Endangered Species Act (ESA) of 1973, as amended, to analyze the effects of both its actions and those of the developer on Northern spotted owl and their critical habitat because of the historic presence of Northern spotted owl core areas. Based upon collected information, BPA has determined that the proposed actions *may affect but are not likely to adversely affect* Northern spotted owl (*Strix occidentalis caurina*) or its critical habitat designated under the ESA. This letter provides documentation for this determination.

![Figure 1. Whistling Ridge Energy Project Location.](image-url)
EFFECTS DETERMINATION

Level of use of the Project Area by Northern spotted owl

Historically, Northern spotted owl activity cores were located on public lands (managed by Washington Department of Natural Resources (WDNR) and the U.S. Forest Service) to the north of the Project Area as seen in Figure 2. These owl cores were designated as the Mill Creek (MSNO#: 0991) and Moss Creek (MSNO#: 1003) cores and were located in Township 4 North and Range 10 East Section 28 and Township 4 North and Range 9 East Section 35, respectively. During both 2008 and 2009, surveys were conducted to these historically-used areas and no spotted owl observations or responses were recorded.

Surveys for the presence of Northern spotted owls were conducted during 2008-2009 within the Project Area. A total of 80 calling stations were established and surveyed during 2008 and no Northern spotted owl responses or observations were noted. Seven supplemental stations were added in 2009 adjacent to areas that were determined to have potential habitat. No observations or detections of Northern spotted owls at any of the 87 established calling stations were noted during 2009.

Northern spotted owl surveys were spread strategically throughout the nesting season in an attempt to see or hear spotted owls. The survey effort covered potentially suitable Northern spotted owl habitat within the approximately 22,123 acres of survey area. There were no Northern spotted owl observations or responses during any of the survey visits.

Additionally, surveys were conducted during the 2003-2004 survey periods. The project site was surveyed from March-July 2003 using the one-year survey methodology, and from March-August 2004 using the two-year survey methodology. USFWS protocol allows a six-visit survey followed by three-visit survey over two years to rule out northern spotted owls for the following two years (USFWS, 1992). No northern spotted owls were detected during the 2003-2004 surveys.
Figure 2. Locations of survey calling stations for Northern spotted owls during 2008-2009.
Effect of the Project on Northern spotted owl’s primary food stocks, prey species, and foraging areas in all areas influenced by the Project

Reduction of suitable habitat poses a significant threat to the Northern spotted owl (habitat in which primary food stocks, foraging, and predation would occur). For the purposes of this Project, potentially suitable spotted owl habitat was determined to be coniferous stands with average tree DBH (diameter at breast height) greater than 12 inches and canopy closure of 60% or greater. These standards for suitable spotted owl habitat were based on the availability of forest stand classification GIS data obtained from SDS Lumber Company. The types of habitats required by spotted owls are typically not present over large areas on managed commercial forest lands. Areas that have been recently cut or areas of young conifer plantations that did not meet the minimum average DBH or canopy closure parameters were excluded from the 2008-2009 survey efforts mentioned above. The resulting designated survey areas did contain varying types of habitat that could potentially be used by spotted owls. With respect to the historical owl cores, data collected by the WDNR and by personnel from the National Council for Air and Stream Improvement (NACASI) indicated that no Northern spotted owl were detected in the Mill Creek core since the 2000 breeding season. Consequently, the Moss Creek core has not had a Northern spotted owl detected since the 2002 breeding season.

During the 2008 and 2009 survey seasons, contract biologists recorded all owl species encountered and the sightings of or responses by potential Northern spotted owl predators. This included barred owls, great horned owls, northern goshawks and other raptor species. As stated above, no Northern spotted owl observations or responses were recorded. However, both of the historic Northern spotted owl cores showed an increased presence of barred owls. Based on the best available scientific information, competition from the barred owl (Strix varia) also poses a significant and complex threat to the Northern spotted owl.

Impacts from Project activities and implementation that may result in disturbance to Northern spotted owl and/or their avoidance of the Project Area

Whistling Ridge Energy LLC has sited its proposed project to avoid habitat areas deemed critical to the Northern spotted owl or essential to its recovery. Surveys conducted pursuant to the USFWS protocol indicate that spotted owls are not present in or near the project, and that nearby historical sites are no longer occupied pursuant to USFWS Protocol and state law. Because there are no Northern spotted owls or activity centers present in the project area, no project construction or operation impacts are expected. Finally, the project would not impact the White Salmon spotted owl special emphasis area’s 40 percent suitable habitat level and therefore is not restricted by Washington’s forest practice regulations. Given the extensive record and review, this project does not pose a risk of taking Northern spotted owls under Endangered Species Act Section 9.
Based on this information, BPA has determined that the proposed actions may affect, but is not likely to adversely affect the Northern spotted owl or its designated critical habitat. BPA is requesting your review on the information contained in this letter and your concurrence with our findings. Please contact me at (503) 230-4145, or e-mail ammontano@bpa.gov, if you have any questions or require additional information.

Sincerely,

/s/ Andrew M. Montaño, June 8, 2010

Subject: Whistling Ridge Energy Project (Your Reference: KEC-4)  

Dear Mr. Montano:  

This letter responds to your request for consultation under section 7(a)(2) of the Endangered Species Act of 1973, (ESA) as amended (16 U.S.C. 1531 et seq.) on the proposed Whistling Ridge Energy Project LLC (Project). Your biological assessment (BA), dated June 8, 2010, was received by the U.S. Fish and Wildlife Service’s (Service) Washington Fish and Wildlife Office on June 9, 2010. You requested concurrence with your determination that the Project “may affect, but is not likely to adversely affect” the threatened northern spotted owl (Strix occidentalis caurina) (spotted owl). No designated spotted owl critical habitat occurs on or near the Project; therefore, no critical habitat will be affected.  

This letter is based on information provided in the BA, the 2009 Final Report “Results of Northern Owl, Western Gray Squirrel and Northern Goshawk Surveys Conducted for the Whistling Ridge Wind Energy Project”, the Draft Environmental Impact Statement, a field trip to the Project attended by staff of the Service and the Washington Department of Fish and Wildlife on May 14, 2009, and a meeting between Service and Washington Department of Fish and Wildlife staff on August 28, 2009.  

Project Location  

The proposed Project is located on private land, approximately 7 miles northwest of the city of White Salmon in Skamania County, Washington. The Project encompasses approximately 1,152 acres of land in sections 5, 6, 7, 8, and 18 of Township 3 North, Range 10 East, and in section 13 of Township 3 North, Range 9 East, Willamette Meridian.
Summary of the Proposed Action

The Bonneville Power Administration (BPA) is proposing to interconnect up to 70 megawatts (MW) of new wind energy from the proposed Project to the North Bonneville-Midway 230-kilovolt transmission line. The interconnect would occur at a new sub-station to be built about 5 miles west of BPA’s Underwood Substation in Skamania County. The interconnect was requested by the Project proponent, SDS Lumber Company, in Bingen, Washington. The SDS Lumber Company has created a new limited liability company called Whistling Ridge Energy LLC (WRE) that would finance, develop, and operate the Project. The Project is expected to operate for at least 30 years. The proposed Project would consist of no more than 50, 1.2 MW-to 2.5-MW wind turbines up to 426 feet tall, as well as infrastructure such as newly constructed and improved roads, transformers, underground energy-collector lines, a substation, and an operations and maintenance facility. The Project area consists of 1,152 acres of mostly commercial forests in various age categories, of which 384 acres would be disturbed by the Project, and all but 61 acres would remain in commercial forest. Most of the property where the turbine strings are planned has been recently clear-cut harvested and will be further disturbed with the development of the turbine pads.

Status of Spotted Owls in the Project Area

Two spotted owl territories are located on Washington State Department of Natural Resources (DNR) and National Forest lands located north of and adjacent to the Project. The site center for the Mill Creek owl (MSNO#0991) is located in Township 4 North, Range 10 East, Section 28 and the site center for the Moss Creek owl (MSNO#1003) is located in Township 4 North, Range 9 East, Section 35. Both of these owl territories are within Washington State’s White Salmon Spotted Owl Special Emphasis Area, which provides added protection for spotted owls located on private lands through the Washington State Forest Practices Rules. Both of the 70 acre core areas are located on DNR lands and are provided additional protection from their Habitat Conservation Plan for the State Trust Lands.

The estimated median annual home range size for the spotted owl in this physiographic province is approximately 6,657 acres, which for regulatory purposes is assumed to lie within a 1.8-mile radius circle. Best available science indicates that when the amount of suitable spotted owl habitat within a circle falls below 40 percent, there is a likelihood of “take” under section 9 of the ESA. Each of these territories contains more than 40 percent suitable spotted owl habitat (J. Spadaro pers. com. 2009). A small portion of the Moss Creek circle overlaps the northern end of the Project and contains dispersal habitat and some foraging habitat. However, removal of this small amount of habitat (2 acres) would not reduce the habitat acreage below 40 percent in either territory.

Protocol spotted owl surveys were conducted within these estimated home ranges during the 2003, 2004, 2008, and 2009 breeding seasons. Numerous barred owls (Strix varia) were detected, but no spotted owls were detected; however, because of the presence of barred owls with these territories, it is possible that spotted owls were present but did not vocalize. The 2009 surveys followed the Service’s revised 2010 protocol to better elicit spotted owl responses in the presence of barred owls (USFWS 2010) (the consultant contacted the U.S. Fish and Wildlife
Service on May 29, 2009, how to call for spotted owls in light of the numerous barred owl detections north of the Project and was provided the changes to the 1992 surveying protocol prior to the release of the 2010 revised protocol on February 18, 2010). However, in 2010 surveys were continued in the Project area. On May 6, 2010, a single male spotted owl was detected while conducting a night visit in the far north edge of the Mill Creek provincial range on DNR property. On May 7th, the biologist conducted a follow-up visit during the daytime. The bird exhibited non-nesting behaviors. On May 29, the biologist conducted a second visit and located what appeared to be the same male owl that was detected on May 7th. The bird on both survey visits took and consumed mice, indicating that it is a single male not supporting young. Spotted owl survey protocol requires 3 sightings of a spotted owl single within the same area within the breeding season to be regarded as a territorial single. This does not change the analyses of effects of the Project to spotted owls, as addressed below, regardless of whether or not a territorial status is established.

Effects from Construction

Approximately 2 acres of spotted owl dispersal habitat (with some patches of foraging habitat) would be removed from the Moss Creek spotted owl site by the construction of the Project from the northern end of the turbine string. This habitat is located at the southern extremity of the circle and is on the edge of the Project that has already been clear-cut by SDS Lumber Company, and would not remove suitable spotted owl habitat below 40 percent in the territory (J. Spadaro pers. com. 2009). The discovery of the new owl in 2010 in the extreme north of the Moss Creek owl circle is located more than 2 miles northwest of the northern most turbine. Because of this, and since the remainder of the Project does not contain suitable spotted owl habitat, we believe that potential effects to spotted owls as a result of habitat loss or degradation is expected to be insignificant.

Effects from Maintenance

The effects of the operation and maintenance of the Project are anticipated to be minor. Maintenance of the Project would occur primarily around the turbine pads, inside the nacelle (the nacelle is the part of the turbine that houses the generator, transmission gears, and the shaft that turns the generator that, on its opposite end, bolts to the hub that the blades attach to) and the blades. In addition, because the landscape will be maintained as young second-growth forest we do not expect disturbance to nesting owls from maintenance because owls are not likely to nest in these younger forest stands (non-habitat).

Risk of Spotted Owl Collision with Wind Turbines

Bird mortality from collisions with wind turbines is well documented and varies greatly by bird species and flight behavior (Smallwood et al. 2009). Spotted owls are forest-dwelling birds that are strongly associated with older conifer forests. Spotted owls primarily use closed-canopy forested habitats throughout their entire lives for nesting, roosting, foraging, and dispersal (Forsman et al. 1984). Because spotted owls are non-migratory, forest-dwelling owls, they are at much lower risk of exposure to wind turbines than many other bird species, which typically use non-forested upland habitats for foraging and migration.
Andrew Montano

Spotted owls less commonly use recent clear-cuts or burned areas for foraging, but spotted owls do occasionally cross such areas while dispersing between patches of older forest (Forsman et al. 1984; 2002). Although spotted owls do occasionally disperse across open areas, they usually avoid crossing such areas by travelling through corridors of forested habitat (Forsman et al. 1984). The typical flight behavior of the spotted owls is described in the *Birds of North America*:

“Quick wingbeats interspersed with gliding flight. Not a fast flier. Long flights unusual except during dispersal...Flight labored when attempting to fly to a higher perch or up to nest sites. When gaining altitude in the forest canopy, makes a series of short climbing flights rather than continuous flight. Flights above the forest canopy probably rare except during dispersal. (Gutierrez et al 1995, p. 9).”

During natal dispersal, spotted owls will occasionally cross open areas and, as noted above, may occasionally fly above the level of the forest canopy. Considering spotted owl flight behavior, above-canopy flights are most likely to occur in steep-walled valley settings, where the spotted owl may choose to fly across a valley above the level of the forest canopy on the valley floor. The Whistling Ridge site is located on a forested ridge top that will be maintained as a cleared area for the wind turbines. Spotted owls dispersing across the ridge are more likely to disperse through forested areas along the perimeter of the site, rather than crossing the open areas near the turbines. If a spotted owl were to fly through the turbine array, it would most likely cross at an altitude that is at or below the level of the adjacent forest canopy, and well below the height of the lower of the wind turbine blades (164 – 425 ft. above ground level).

To assess the risk of owl collision with the turbine blades or towers, we convened a review panel of three spotted owl biologists from this office and one spotted owl biologist from the Washington Department of Fish and Wildlife. Based on our knowledge of spotted owl flight behaviors and habitat preferences, the group concluded that the risk of spotted owl collisions with turbines at this site is low.

Considering the strong association of spotted owls with the forest canopy, and spotted owl flight behaviors, we conclude that it is unlikely that spotted owls would cross the Whistling Ridge site at an altitude that would put the owls at risk of collision with turbine blades. Therefore, the risk of a spotted owl collision at this site is considered to be discountable.

**Concurrence**

Considering the current status of spotted owls in the Project area, and the anticipated Project effects, we concur that the Project is not likely to adversely affect the spotted owl.

This concludes informal consultation pursuant to the regulations implementing the ESA (50 CFR 402.13). This action should be re-analyzed if new information reveals effects of the action that may affect listed species or designated critical habitat in a manner or to an extent not considered in this consultation; if the action is subsequently modified in a manner that causes an effect to a listed species or designated critical habitat that was not considered in this consultation; and/or, if a new species or critical habitat is designated that may be affected by this Project.
Other Comments

While reading through the DEIS for this Project, we found some issues that require your attention. On Page 4-4, first paragraph, last sentence “As described in Section 3.4 Biological Resources, no listed species or critical habitat are anticipated to be affected by the Project. This statement equates to a finding of no effect. To the contrary, the biological assessment prepared by BPA made a finding of “may affect, not likely to adversely affect”; hence, the need for this informal consultation.

On page 4-5, 4.5 Migratory Bird Treaty Act, both the interpretation of this Act and the effects of the Project to avian species are in error. Both avian studies and the analyses in Section 3.4 Biological Resources state that many avian species occur within the Project and that some of those individuals will be killed (collisions with blades or tower) and contrary to the statements provided in the Biological effects Section. Within this context, how is it concluded at 4.5, that impacts to migratory birds could only occur through temporary disturbance during construction?

On page 4-5, 4.7 Bald Eagle Protection Act, the last statement “Because the Project would not involve intentional acts or acts in wanton disregard of bald or golden eagles, this Project is not considered to be subject to compliance with the Act.”, is an inaccurate statement. Federal Law Enforcement and the U.S Department of Justice decide whether or not an eagle killed by a project is subject to compliance under this Act.

The Service appreciates your efforts to protect listed species and the habitats on which they depend while meeting your mission to provide the public with reliable electricity. If you have any questions regarding this consultation or your responsibilities under the Act, please contact Jim Michaels of this office at (360) 753-7767.

Sincerely,

[Signature]

Consultant Disclosure Statements
NEPA DISCLOSURE STATEMENT FOR PREPARATION OF THE
Whistling Ridge Energy Project
Draft Environmental Impact Statement
DOE/EIS-0419

CEQ Regulations at 40 CFR 1506.5(c), which have been adopted by the DOE (10 CFR 1021), require contractors who will prepare an EIS to execute a disclosure specifying that they have no financial or other interest in the outcome of the project. The term “financial interest or other interest in the outcome of the project” for purposes of this disclosure is defined in the March 23, 1981 guidance “Forty Most Asked Questions Concerning CEQ’s National Environmental Policy Act Regulations,” 46 FR 8026-18038 at Question 17a and b.

“Financial or other interest in the outcome of the project” includes “any financial benefit such as a promise of future construction or design work in the project, as well as indirect benefits the contractor is aware of (e.g., if the project would aid proposals sponsored by the firm’s other clients).” 46 FR 18026-18038 at 18031.

In accordance with these requirements, the offeror and any proposed subcontractors hereby certify as follows: (check either (a) or (b) to assure consideration of your proposal).

(a) ______ Offeror and any proposed subcontractor have no financial or other interest in the outcome of the project.
(b) ______ Offeror and any proposed subcontractor have the following financial or other interest in the outcome of the project and hereby agree to divest themselves of such interest prior to award of this contract.

Whistling Ridge Energy Project
Draft Environmental Impact Statement
DOE/EIS-0419

CEQ Regulations at 40 CFR 1506.5(c), which have been adopted by the DOE (10 CFR 1021),
require contractors who will prepare an EIS to execute a disclosure specifying that they have no
financial or other interest in the outcome of the project. The term “financial interest or other
interest in the outcome of the project” for purposes of this disclosure is defined in the March 23,
1981 guidance “Forty Most Asked Questions Concerning CEQ’s National Environmental Policy
Act Regulations,” 46 FR 8026-18038 at Question 17a and b.

“Financial or other interest in the outcome of the project” includes “any financial benefit such as
a promise of future construction or design work in the project, as well as indirect benefits the
contractor is aware of (e.g., if the project would aid proposals sponsored by the firm’s other
clients),” 46 FR 18026-18038 at 18031.

In accordance with these requirements, the offeror and any proposed subcontractors hereby
certify as follows: (check either (a) or (b) to assure consideration of your proposal).

(a) □ Offeror and any proposed subcontractor have no financial or other
interest in the outcome of the project.

(b) _____ Offeror and any proposed subcontractor have the following financial or
other interest in the outcome of the project and hereby agree to divest
themselves of such interest prior to award of this contract.

INTRODUCTION

This Appendix presents and responds to all substantive comments received during the public comment period for the Whistling Ridge Energy Project Draft Environmental Impact Statement. The substantive comments and their respective responses are organized and presented by topic or subject area following the organization of this EIS (based on the topic of the comment received). Each comment is identified by the following notation: \([LRT \, X, \, CMT \, X]\). Each letter that was received by both BPA and EFSEC was given a numerical letter identifier \((LTR \, X)\). Furthermore, each substantive comment within each letter was given a numerical comment identifier \((CMT \, X)\). Non-substantive comments (general comments) and their respective responses that were received for this proposed project begin on page 593 of this Appendix.

An index to Appendix G is provided to facilitate the identification of the numerical identifier of each letter. A table of contents to Appendix G is provided to present the topic chapter organization of the comments and their responses, as well as what page these topics can be found on. If a reader is interested in a particular issue or topic, they should refer to the table of contents of Appendix G. If a reader is interested in learning what letter number their comment letter was assigned, they should refer to the index of Appendix G. A digital copy of this Appendix can be downloaded from the project website, http://www.bpa.gov/go/whistling. By downloading a copy of this Appendix, the viewers may search for their parsed comments within the Appendix using the search function to locate references to their particular letter notation \((LTR \, X)\). You may also request a digital copy of this Appendix by calling 1-800-622-4520 and asking for the document by name. Or, requests for electronic copies can be obtained by writing to:

Bonneville Power Administration  
P.O. Box 3621  
Portland, Oregon 97208  
ATTN: Public Affairs Office – DKE-7

All comment letters received by both Agencies can be viewed in Appendix H of the EIS. Combined, both Agencies received the following amount of comments from the public’s review of the Draft Environmental Impact Statement:

- 320 individual letters were received (not counting duplicate form letters).
- 608 letters were received (counting form letters from different individuals).
- 2,168 parsed comments were sent out for response and are addressed in this Appendix.
This page intentionally left blank.
G.1 SUMMARY AND PURPOSE OF AND NEED FOR ACTION

Comment: Why did you decide this was the best spot? [LTR 22, CMT 2]

Response: The lead agencies believe that the DEIS presented a reasonably thorough discussion of the consideration of alternatives for the proposed action, including why alternative locations were not being further studied. The reasons that the Applicant proposed the Project at this particular location are explained in Sections 1.4.1 and 2.3 of the EIS. As discussed in these sections, a variety of factors were considered in evaluating whether alternative locations might be feasible. To further clarify this consideration, Section 2.3.1 of the EIS has been revised to provide additional information on alternative locations that were considered for the proposed Project. Issues raised concerning alternative configurations for the proposed Project are addressed in other response to comments in this section.

Comment: Why are other spots not as desirable? [LTR 22, CMT 3]

Response: Please see response to Comment LTR 22, CMT 2 above.

Comment: Why are they [the turbines] placed so that the majority of the central gorge will be seeing them? [LTR 22, CMT 5]

Response: The concerns over turbine corridor A1-A7 are noted. As discussed in the EIS, however, the Project has been proposed as an “integrated whole”, meaning essentially as a single power plant, not as a dissectible project where some turbines may be eliminated. An alternative that would eliminate turbine corridor A1-A7 therefore was considered and eliminated from further study. Nonetheless, in determining whether to issue a site certificate and enter a site certificate agreement for a proposed generation project, it is within authority of the State of Washington to condition approval of the proposed Project, consistent with RCW 80.50 and other applicable state statutes. In the draft certification agreement, EFSEC is empowered to include “conditions to protect state or local governmental or community interests affected by the construction or operation of the energy facility.” See RCW 80.50.100. These conditions essentially serve to mitigate potential environmental or social impacts of the proposed Project. Accordingly, certain conditions, such as limiting the location of proposed turbine corridors, could be considered as a condition for Project approval (i.e., as a form of mitigation related to the Project’s potential impacts).

Comment: From an economic perspective, the wind farm is supposed to generate power for 20,000 homes. This seems like very few homes for the cost, environmental impact, and degradation of a rural landscape. What would the cost be of conservation efforts to save the equivalent about of energy? We would assume that it would cost far less to save an equivalent
amount of power by practicing state of the art energy conservation measures than by generating new energy using wind turbines. Let’s look at the real costs of wind power! We are residents of the Columbia Gorge and we oppose this project. [LTR 33, CMT 6]

Response: As discussed in Chapter 1 of the EIS, the lead agencies need to respond to an application and request to site and interconnect a proposed wind project. While conservation could help meet the region’s need for power, it would not be responsive to the Applicant’s proposal to develop a wind project. Although conservation is not an alternative to the agencies’ proposed actions, it is acknowledged in the EIS as a likely method by which energy needs in the region could be met if the No Action alternative was selected.

Comment: The DEIS erred in its analysis of the regional need for new sources of renewable energy. The DEIS cites the Draft Sixth Northwest Power Plan released in September 2009 by the Northwest Power and Conservation Council. What the DEIS fails to quantify is that this 20-year energy plan for our region concluded that, although population and energy demands will continue to grow in the Pacific Northwest, we can meet 80 percent of expected future energy demands through conservation efforts and improved energy efficiency. Conservation efforts not only have less environmental impact than building new energy sources, they are also considerably less expensive. Only about 20 percent of future needs must come from new sources of energy, according to the Council. And shown above, with 40 wind projects already constructed or proposed for this region, there are plenty of new sources to meet these needs.

There is no demonstrated need for Whistling Ridge. The dirty little secret of wind power in the Columbia Plateau Ecoregion is that most of the electricity being generated here by wind turbines is not needed or used in the Pacific Northwest. Instead it is sold to utilities in California. There is regional need for new power sources; there is simply a California demand for electricity generated in Washington and Oregon. On page 3-91 of the DEIS, the applicant claims that the Klickitat County Energy Overlay Zone Final EIS “recently evaluated the projected energy demand in Klickitat County, Washington, the county immediately adjacent to Skamania County.” (In fact, this evaluation is already more than six years old). The DEIS then mentions the EIS projection that “four wind power projects with total generating capacity of 1,000 MW” will be developed in Klickitat County by 2024. In fact, Klickitat County has already approved more than a dozen projects, with a total generating capacity of almost 2,000 megawatts. Rather than suggesting that more energy is needed regionally, this rapid development of wind power in Klickitat County indicates that more than enough wind power is already under development to meet the region’s energy needs. [LTR 36, CMT 9]

Response: The EIS analyzes the potential impacts of the proposed Project and is not intended to analyze regional need for renewable resources. Information presented in the EIS concerning the Northwest Power Plan is intended to provide context for the applicant’s belief that there is sufficient need to support its proposal. The commenter’s interpretation of the Northwest Power Plan and its relation to the Applicant’s stated need for the Project is acknowledged.
Comment: Thank you for the opportunity to comment on the DEIS for Whistling Ridge. After reading though this document, I was struck by the generic and generally outdated content. I understand the need to plagiarize other EIS’s to lessen preparation efforts; however, it does worry me that this project is not being looked at for the uniqueness of this site, and the natural and scenic resources. [LTR 60, CMT 1]

Response: The opinions of the commenter concerning the completeness and adequacy of the DEIS are noted. EFSEC and BPA believe that the DEIS contains a reasonably thorough analysis of the potential environmental impacts of the proposed Project, as required by SEPA and NEPA. As discussed in the DEIS, environmental information was compiled based primarily on site-specific field studies, literature reviews, and communications with various knowledgeable resource agencies. Any assumptions made in the analysis were explained to the extent appropriate, and every attempt was made to use the most current data and information reasonably available. Specific issues with the DEIS analysis that are raised in these comments are addressed in the appropriate sections of these responses to comments.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS and issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. [LTR 66, CMT 4]

Response: The opinions of the commenter concerning the sufficiency of the DEIS are noted. EFSEC and BPA believe that the DEIS contains a reasonably thorough discussion of the potential environmental impacts of the proposed Project and allows for meaningful analysis of the Project and its impacts, as required by SEPA and NEPA. As such, the lead agencies believe that a supplemental draft EIS is not necessary. As discussed throughout these responses to comments, appropriate clarifications and modifications to the EIS analysis as a result of public comment are contained in the Final EIS for this Project, as allowed under both SEPA and NEPA.

Comment: I also request that EFSEC and BPA extend the comment period in order to allow the public sufficient time to review and comment on the 1,578 pages of material contained in the DEIS and appendices. Please extend the comment period by 45 days. [LTR 66, CMT 5]

Response: BPA and EFSEC initially allowed a 45-day public review and comment period for the DEIS, which is consistent with NEPA and SEPA regulations for allowing adequate time for DEIS review and comment. In order to further facilitate public involvement however, the lead agencies agreed to extend the end of the original comment period (July 19, 2010) for an additional 39 days (to August 27, 2010), thereby allowing a total of 91 days for public review and comment on the DEIS. The lead agencies provided timely and broad distribution of the DEIS, wide noticing, web postings, and periodic updates to ensure sufficient public awareness of the DEIS and comment period. The lead agencies also posted the DEIS on the agencies’ websites and held public meetings on the DEIS to ensure that the public was provided with opportunities for involvement.
Comment: Please hold another hearing, give us more than 3 weeks to analyze 1500 pages of technical material. [LTR 67, CMT 1]

Response: EFSEC and BPA held two public meetings in mid June 2010 to receive comments on the DEIS. In addition, as discussed above, EFSEC and BPA provided a 91-day public review and comment on the DEIS (i.e. May 28, 2010 to August 27, 2010). EFSEC and BPA believe this provided sufficient opportunities for public review and comment.

Comment: The applicant says that he cannot go below 70mW and is trying to disguise his unwillingness to minimize this project by saying that public utilities seeking to fulfill their RPS requirements need a minimum of this kind of output “to be attractive.” [LTR 74, CMT 3]

Response: As discussed in Section 2.3.2 of the EIS, the Applicant considers a 70-MW project as the minimum size required to make the proposed Project economically feasible. In addition, the Applicant believes this is the minimum size needed for utilities looking to fulfill RPS requirements, based on the Applicant’s assessment of other wind projects that have successfully entered purchase agreements with utilities seeking to meet RPS requirements. The lead agencies believe these are reasonable requirements for the proposed Project.

Comment: Pg. 1-7 states that “No other federal agencies have been identified as cooperating agencies for this EIS at this time.” Cooperating, hmmm, is that because the NPS and FS have made concerned negative comments about this proposal as it now is written. [LTR 74, CMT 4]

Response: No federal agencies are cooperating agencies for this EIS because no such agencies have formally expressed an interest in acting as a cooperating agency. As is noted in Chapter 1 of the EIS, however, the lead agencies, along with the Applicant, have conducted extensive outreach to various federal, state, local, and tribal agencies and entities to help identify any issues concerning the proposal to be addressed in the EIS.

Comment: On [DEIS] page 1-8 it states that “Other federal, state or local agencies also may have permitting or other approval authority for the proposed Whistling Ridge Energy Program. Those agencies may use this EIS in order to fulfill NEPA or SEPA responsibilities.” Those agencies have an obligation to the public to do their own due diligence and evaluations, not depend on the project proponent’s potentially biased data. This EIS states that the BPA substation would cover “4.25 acres and be sufficient for future installation of equipment if required for future development.” What kind of future development -- 50 more wind turbines? I am concerned with scope creep. With the national and state mandates on “going green” I can see how once they are in, it would be much easier to expand the number of turbines. I don’t want to see this project look like the Klickitat projects [LTR 74, CMT 6]
Response: A summary of the required permits and approvals for the proposed Project and the responsible federal, state or local agencies can be found in Table 4-1 in Section 4.0 of the EIS. Section 4.1 also describes the statutes under NEPA and SEPA that require state and federal agencies to “take action to assess, consider, and disclose the potential impacts of their proposed actions on the environment.” While other federal, state or local agencies may choose to use this EIS to help fulfill their NEPA or SEPA responsibilities, those agencies would be responsible for independently evaluating the information and analysis it contains to determine if this EIS satisfies their regulatory responsibilities. Those entities may determine that additional studies, review or public involvement are required to satisfy their requirements. There are currently no future requests in BPA’s interconnection queue for new generation to interconnect at BPA’s proposed new substation, and the transmission lines in the area will be near capacity if the decision is made to interconnect the generation from the proposed Project. The operation of the FCRTS within BPA’s Balancing Authority often necessitates changes, upgrades or expansions to existing electrical yards and components in response to regional operational changes or adjustments. In the event that BPA receives future requests to interconnect electrical generation or determines a need to make changes to the proposed substation in response to the operation of the FCRTS, the resulting federal action would require an independent review under NEPA.

Comment: During a brief review of the referenced document, I was startled to note the appearance throughout, of a distinct bias. Right off the bat, in [DEIS] section 1.2.3.3, a discourse of almost a full page of text - five paragraphs worth - is entitled “Business Needs of the Applicant.” No-one’s “business need” is appropriate material for discussion in any EIS document, for what, I hope, are obvious reasons. (Only in a totalitarian regime is the “need” or desire of an individual more important than large-scale human, wildlife and scenic resources.) The only material in this section that is relevant- that dealing with the large number of temporary construction jobs that would result, and the small number of permanent jobs after project completion belongs elsewhere. [LTR 76, CMT 2]

Response: The lead agencies believe that it is appropriate that the EIS identify the Applicant’s stated reasons for proposing its wind project. These reasons help provide context for why the Applicant has made its proposal, and what objectives it hopes to achieve through its proposal.

Comment: I plan to submit a lengthier statement dealing with additional issues by the July deadline. Thank you for the opportunity to comment, if only in a cursory manner. I realize that it would take a great deal of your time, but it would be wonderful if a more generous amount of time were allotted to speak, especially on an issue with so many facets of concern. [LTR 76, CMT 12]

Response: Please see response to Comment LTR 66, CMT 5 above.
Comment: Amid the draft’s generally lucid narrative is the following mysterious sentence on page 1-9: “The site has a long history of commercial logging and associated absence of native habitat, reducing or eliminating the need to clear additional forest land.” Could someone decipher that for us? [LTR 79, CMT 13]

Response: The Applicant has owned this land since the 1940s and prior to their ownership, the Project Area has been actively logged since the early 1900s. Areas of Development that are being proposed can be further broken down on Table 2-1. Current forest types within the Project Area are described on Figure 2-2 and harvesting schedules are described on Figure 2-3. The summation sentence referenced on DEIS page 1-9 as commented upon is pointing out that additional forest clearing may not necessarily be needed due to the current forest types currently seen within the Project Area as well as tree harvest schedules.

Comment: We submitted Scoping comments, dated 5/15/2009, for this EIS. After reviewing the DEIS, we are of the opinion that, while the DEIS contains massive amounts of information on topics related to the issues we raised, the DEIS fails to directly address and respond to most of our concerns in a meaningful way. We have therefore resubmitted our previous comments in their entirety, and request that EFSEC and BPA revise the DEIS to respond directly and specifically to the concerns that our community has. Our residents have invested significant amounts of time, energy, money, and especially emotion in building homes and lifestyles focused on our rural, sylvan environment. While we have always known we would be affected by various rural activities such as agriculture and timber operations, we never anticipated that a major industrial activity like a wind farm could be located so near to us. We have grave concerns about several possible adverse effects of the project, and consequent reservations about the location of the Project. [LTR 119, CMT 2]

Response: EFSEC and BPA considered all comments received during the scoping period for this Project, and made good faith efforts to attempt to ensure that the DEIS addressed all comments relevant to environmental concerns. In addition, many of the same issues raised in the scoping process were also raised in comments on the DEIS, and are thus addressed herein. In doing so, the lead agencies believe that they have adequately addressed comments made through the EIS process.

Comment: Precedent. We believe it is critical that the EIS address the potential precedent that would be set by approval of this Project. Because it is the first wind farm in Washington to be located in a forest environment (we are told), adjacent to a National Scenic Area, and close to so many residences, a very detailed and thorough analysis of its potential impacts must be provided. Approval of the current application for this project will have precedential effect not only for projects in other regions, but also for expansion of this Project. SDS and DNR have acknowledged that they are investigating a major possible expansion of this Project onto DNR land. We do not know if SDS will seek to expand this Project even further on its own adjacent lands (which would be closer to our community.) However, we are worried that if this Project is approved now based on its smaller size, it will be very difficult to prevent expansions that might
initially have been rejected based on an upfront perspective of the total impacts. Consequently, we request that the EIS take the broadest possible view when evaluating the impacts of this Project. [LTR 119, CMT 11]

Response: It is unclear at this time whether approval of the proposed Project would set a precedent for siting other wind projects in the area. Since all projects are evaluated on a case-by-case basis, approval of this Project does not dictate that any other Project that may be proposed in the future would also be approved. In addition, most developers are aware of the challenges of attempting to site wind projects in this general area. For the Applicant, proposing a wind project in this area may make sense, but other wind project developers may have differing opinions. Nonetheless, because there are no current proposals for other wind projects in the area; such future development is considered too speculative at this time.

Comment: I request that EFSEC and BPA extend the comment period by 45 days, in order to allow the public sufficient time to review and comment on the 1,578 pages of material contained in the DEIS and appendices. [LTR 127, CMT 4]

Response: Please see response to Comment LTR 66, CMT 5 above.

Comment: The public must also be kept informed about the environmental impacts of the project, so please extend the comment period by 45 days. [LTR 130, CMT 3]

Response: Please see response to Comment LTR 66, CMT 5 above.

Comment: Related Concerns: 1. A first Gorge Windmill project will set a precedent. Other proposals and very likely other windmill farms will follow. New companies (for example a conglomerate such as General Electric) will be much less concerned about the welfare of this area than our neighbors at SDS. [LTR 135, CMT 3]

Response: Please see response to Comment LTR 119, CMT 11 above.

Comment: Huge steel towers with massive concrete bases would be with us a very long time. The costs of removing an obsolete windmill would be substantial. But how long would a wind tower be useful? [LTR 135, CMT 7]

Response: As discussed in Section 2.1.7 of the EIS, the proposed Project, including the wind turbines, is expected to have a useful life of at least 30 years. However, it is possible (and generally likely) that in the future, aging project components would be replaced as needed, which

G-11
could extend the useful life of the Project for years or even decades beyond the current expected project lifespan.

**Comment:** In our testimony of May 6, 2009 we specifically requested that three issues be directly addressed within the scope of the proposed Whistling Ridge Energy Project EIS. The current draft EIS does not adequately address the three issues. [LTR 139, CMT 1]

**Response:** Please see response to Comment LTR 119, CMT 2 above.

**Comment:** The third issue we raised was partially resolved, not due to your actions, but as a result of a decision rendered by DNR, which prevented, at least temporarily, the leasing of adjacent DNR land to SDS for placement of additional wind turbines. We are still greatly concerned that this proposed project is reportedly the first of its kind in forested habitats in Washington. This begs the need for intelligent planning, caution and due consideration given the potentially profound impact on watersheds, wildfire risk, bats, avian species, mammals and humans. We feel greatly disappointed that the current draft EIS appears to hide behind outdated and inadequate state regulations, and pray that EFSEC and BPA will yet demonstrate desperately needed leadership in adopting a quality and accurate model for wind turbine siting that is in harmony with the environment while providing ample protection for the health and quality of life of all Washington residents. [LTR 139, CMT 25]

**Response:** Please see response to Comment LTR 119, CMT 2 above.

**Comment:** There has not been enough time for the average citizen to go through the EIS! Most people I’ve spoken with haven’t still have not seen the EIS. [LTR 142, CMT 1]

**Response:** Please see response to Comment LTR 66, CMT 5 above.

**Comment:** At the last public hearing on Whistling Ridge, numerous public participants, including the Yakama Tribe asking for government to government contact, asked for more time to dissect the 1500+ DEIS for this proposed wind farm. Have you all made any decision to prolong the 30-day comment period? Frankly, 30 days is not enough time to dissect, digest, analyze, and make coherent comments upon, such a monster DEIS. I would like to see the public participation process extended to a more reasonable comment period. Thank you. [LTR 143, CMT 1]

**Response:** Please see response to Comment LTR 66, CMT 5 above.
Comment: I am writing to request that you extend the comment period on the DEIS for the Whistling Ridge Energy Project. I received my hard copy of this 1500 page document on Monday, July 12, 2010. I requested it at the Underwood hearing on June 16th, after finding that looking at it online was not practical (hard to flip back and forth to cross-reference, etc.) and printing it on my printer impractical, too. When I tried to look at it at the library in White Salmon, I was only given the DEIS without the appendices. To summarize, I have been given less than a week to review a complex, 1500 page document. I am probably not the only one. We were assured at the hearings by Jim Luce that hard copies would be available on request. I think he thought we would get them in a more timely manner. A week is not enough time to assimilate the information, let alone formulate constructive comments. I respectfully request that your agencies extend the comment period at least 60 days. A cursory review of the document reveals much happy talk and shallow analysis of major issues associated with this project. I would like to provide detailed and meaningful input to this process, but will need more time. As I stated at the hearing, my community of Underwood, through which all construction traffic will be routed, feels like it is getting the bum’s rush by your agencies and the applicant. As the first project of its kind in a forested, mountainous setting, on the doorstep of a internationally recognized scenic wonder, we hope that the process will be fair and thorough. [LTR 144, CMT 1]

Response: Please see response to Comment LTR 66, CMT 5 above.

Comment: I am writing on behalf of Friends of the Columbia Gorge to request that the agencies extend the deadline for written comments on the Whistling Ridge Energy Project DEIS. We request an extension of 45 days in order to have sufficient time to review the 1,500 pages of material in the DEIS and appendices and make meaningful, informed comments. Until very recently, Friends’ staff, consultants, and outside legal counsel have had a total of only two paper copies of the DEIS to use in our review. Essentially, nine different people in five different offices have had to share two paper copies. One of our consultants is often in the field and away from a computer; a paper copy has been essential for his review. Friends’ staff attended the June 16 and 17 public hearings in Underwood and Stevenson. At those meetings, EFSEC Chair Luce stated that paper copies would be provided to the public upon request. Friends’ staff requested three additional copies of the DEIS by checking the appropriate box on the sign-in sheets. On June 21, I requested by phone and email four paper copies of the DEIS from EFSEC. On July 7, not having received the copies, I reiterated the request by email. On July 12, Friends’ staff finally received two additional paper copies. This was only one week before the comment deadline of July 19. We certainly understand that the EFSEC and BPA staff are overwhelmed with the regular press of business, not to mention furlough days and special projects. We do not fault the agency staff for the delays in distributing paper copies. However, we believe it is only fair for the agencies to extend the comment deadline, in order to give the public sufficient time to review and comment on the material in the DEIS. We are also sympathetic to the impact on the citizens of the Gorge. I have spoken to other people who received their first and only paper copy this week, after requesting it almost a month ago. Some citizens in rural areas of the Gorge are still using dial-up Internet access, or have no Internet access at all. For these citizens, obtaining electronic copies via the Internet was never an option. They are now left with an insufficient amount of time to digest 1,500 pages of material and write meaningful comments. Friends
respectfully requests an extension of the comment period on the DEIS. Thank you for considering this request. [LTR 145, CMT 1]

Response: Please see response to Comment LTR 66, CMT 5 above.

Comment: I would like to request an extension of 30-45 days for the deadline for written comments on the DEIS for the Whistling Ridge Energy Project in order to have sufficient time to review, digest and then make meaningful comments on this proposal since this will be the one and only opportunity as a concerned Gorge resident to do so. This document along with its appendices is an enormous amount of material to try and make informed comments on since I only received my hard copy a matter of several weeks ago and I have dial-up internet at my home in the West end of Skamania county and simply can’t download this material in any sort of realistic timeframe. I attended both the June 16th and 17th public hearings in Underwood and Stevenson where several other concerned citizens voiced their concerns that this is not an adequate amount of time for proper public review. As a resident of the Columbia River Gorge living in Skamania county for the past 16 years, I respectfully request that you allow for an extension for the public comment period on this DEIS of the Whistling Ridge Wind Energy Project. [LTR 146, CMT 1]

Response: Please see response to Comment LTR 66, CMT 5 above.

Comment: I am writing to request an extension to the comment period for the WRE DEIS. I was able to obtain a hard copy of the DEIS from EFSEC’s kind staff at the Underwood DEIS public meeting in mid-June. Since that time, of slightly less than 30 days, I have read through and marked up my copy, but still have not finished compiling and commenting, due to the complexity and size of the DEIS. Please provide additional time for the public to offer meaningful comments. [LTR 147, CMT 1]

Response: Please see response to Comment LTR 66, CMT 5 above.

Comment: This office represents Save Our Scenic an interested party to the proposed Whistling Ridge Energy project. Given the length of the DEIS and the detailed materials found therein, we join in the request of Friends of the Columbia Gorge (Friends) to extend the comment period for 45 days to allow full opportunity to comment on this DEIS as well as to provide additional notice to interested persons. [LTR 148, CMT 1]

Response: Please see response to Comment LTR 66, CMT 5 above.
Comment: Based on the foregoing, SOSA requests that the comment period for the DEIS be extended for at least 45 days. [LTR 148, CMT 4]

Response: Please see response to Comment LTR 66, CMT 5 above.

Comment: They own lots of land (70,000 acres, according to Wally Stevenson) and can find another way to make money on it. There is another reason I question this project. The Northwest Power and Conservation Council’s 6th Plan ranks conservation ahead of wind power in terms of cost-effectiveness. I work on verifying conservation technologies and, for the most part, they do work. The hardest part has been finding someone to do the work (thankfully that is now changing) but the results have been proven in a number of regional studies that extending back to the early 1980s. There is still a lot of conservation to procure, and the economics are considerably more favorable than the economics of wind, especially when real utilization factors are employed. (That is, turbines even in very windy places only generate usable electricity about 40% of the time; most turbines have much lower utilization rates.) I urge EFSEC to consider these issues seriously when ruling on the siting application. [LTR 153, CMT 2]

Response: Please see response to Comment LTR 33, CMT 6 above.

Comment: I also request that EFSEC and BPA extend the comment period in order to allow the public sufficient time to review and comment on the 1,578 pages of material contained in the DEIS and appendices. Please extend the comment period by 45 days. [LTR 154, CMT 2]

Response: Please see response to Comment LTR 66, CMT 5 above.

Comment: The DEIS erred in its analysis of the regional need for new sources of renewable energy. The DEIS cites the Draft Sixth Northwest Power Plan released in September 2009 by the Northwest Power and Conservation Council. What the DEIS fails to quantify is that this 20-year energy plan for our region concluded that, although population and energy demands will continue to grow in the Pacific Northwest, we can meet more than 80 percent of expected future energy demands through conservation efforts and improved energy efficiency. Conservation efforts not only have less environmental impact than building new energy sources, they are also considerably less expensive. Less than 20 percent of future needs must come from new sources of energy, according to the Council. And shown above, with 40 wind projects already constructed or proposed for this region, there are plenty of new sources to meet these needs. There is no demonstrated need for Whistling Ridge. The dirty little secret of wind power in the Columbia Plateau Ecoregion is that most of the electricity being generated here by wind turbines is not needed or used in the Pacific Northwest. Instead it is sold to utilities in California. There is no regional need for new power sources; there is simply a California demand for electricity generated in Washington and Oregon. On page 3-91 of the DEIS, the applicant claims that the Klickitat County Energy Overlay Zone Final EIS “recently evaluated the projected energy
demand in Klickitat County, Washington, the county immediately adjacent to Skamania County.” (In fact, this evaluation is already more than six years old). The DEIS then mentions the EIS projection that “four wind power projects with total generating capacity of 1,000 MW” will be developed in Klickitat County by 2024. In fact, Klickitat County has already approved more than a dozen projects, with a total generating capacity of almost 2,000 megawatts. Rather than suggesting that more energy is needed regionally, this rapid development of wind power in Klickitat County indicates that more than enough wind power is already under development to meet the region’s energy needs. Existing wind projects in this region are already producing so much surplus power that there are times when these projects must be turned off to protect the regional grid. For example, see these recent articles on the surpluses in the Columbia River corridor: http://green.blogs.nytimes.com/2010/07/07/sudden-surplus-calls-for-quick-thinking/, and http://www.oregonlive.com/business/index.ssf/2010/06/swollen_columbia_river_chums.html. [LTR 161, CMT 10]

Response: Please see response to Comment LTR 36, CMT 9 above.

Comment: The DEIS overwhelms the public with quantity but not quality. I am grateful for the extended comment period. Nevertheless, it is not reasonable to expect members of the general public to be able to digest and respond intelligently within just a few weeks to a record that is thousands of pages long and years in the making. Despite this huge volume of material, there is very little scientific literature cited in the DEIS, and even less that is peer-reviewed science. The applicant has cherry-picked a few statistics and extrapolations from industry-sponsored reports and ignored the independent science and actual mortality studies that suggest major cumulative impacts are likely for wildlife given the pace and scope of wind power development in this region. Thank you for the opportunity to comment on this project. [LTR 161, CMT 14]

Response: Please see response to Comment LTR 60, CMT 1 above.

Comment: Joint EFSEC/BPA preparation. As the DEIS introduction at paragraph 1.1 clearly states, both the Energy Facility Site Evaluation Council (EFSEC) and the Bonneville Power Administration (BPA) have jointly prepared the DEIS to be consistent with the requirements of both the Washington State Environmental Policy Act (SEPA) and the National Environmental Policy Act (NEPA). Although the document is consistent with SEPA requirements, its form has been modified, adjusted and expanded where appropriate to ensure compliance with NEPA as well. Accordingly, the DEIS is now a federal NEPA document and not just an EIS generated by the project applicant. [LTR 162, CMT 8]

Response: The lead agencies believe that they have produced a reasonably thorough analysis of the proposed Project that adequately considers all points of view. BPA and EFSEC staff actively and extensively participated in the preparation of the EIS, as required by SEPA and NEPA. Both SEPA and NEPA allow for the use of environmental information, in whatever
form, from the Applicant for use in the preparation of an EIS. In fact, SEPA allows for an applicant to prepare the EIS. Nonetheless, where the lead agencies used information provided by the Applicant or its consultants, this information was thoroughly reviewed and independently evaluated by the agencies to ensure its competency and accuracy. This approach is consistent with the intent of SEPA and NEPA that acceptable environment work not be redone, but that it instead simply be verified by the lead agency. The lead agencies have taken full responsibility for the scope and content of the EIS, and have fulfilled their respective responsibilities for EIS preparation under SEPA and NEPA.

Comment: In addition, the DEIS has been prepared in direct collaboration with a sufficiently wide range of state and federal wildlife agencies and tribal governments (8), including: the Washington Dept. of Archeology and Historic Preservation, Washington Department of Fish and Wildlife, Washington State Department of Natural Resources, Washington State Department of Transportation, U.S. Army Corps of Engineers, U.S. Fish and Wildlife Service, and the Yakama Nation. The pre-development biological survey work was done in collaboration with the Washington and U.S. Fish and Wildlife Departments. [LTR 162, CMT 8]

Response: Please see response to Comment LTR 74, CMT 4 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS and issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 163, CMT 3]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS and issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 165, CMT 3]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS and issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 167, CMT 3]

Response: Please see response to Comment LTR 66, CMT 4 above.
Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS and issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 169, CMT 3]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Based on the foregoing, SOSA still believes that the correct procedure to be followed, and one authorized by the rules under both SEPA and NEPA, is to issue a supplemental DEIS (SDEIS) correcting basic errors in the issued DEIS. The SDEIS would be subject to comment by interested agencies and members of the public. [LTR 176, CMT 4]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Third, the DEIS cites numerous public documents that the project will supposedly comply with, including the Fifth Northwest Electric Power and Conservation Plan (DEIS at 1-4), the draft Sixth Northwest Electric Power Plan (“NPCC 2009”, DEIS at 1-5), the “establishment of Renewable Portfolio Standards (RPS) at the state level” (DEIS at 1-5), the requirement for “qualified alternative energy products” pursuant to state law (DEIS at 1-5). Each of these regulations and policies is substantially similar to the relationship between Pierce County and the developer in the Weyerhaeuser case. The DEIS touts the current proposal as meeting public needs and legislative mandates. WRE cannot promote the project “public” for one purpose, but claim it is “private” for another, especially where careful review of alternatives is required by SEPA and NEPA. [LTR 176, CMT 8]

Response: The public documents referenced by the commenter are not identified as documents that the Project will comply with; rather, as indicated on page 1-4 of the EIS, these documents have been identified by the Applicant as sources that the Applicant believes point to the regional need for renewable resources such as the proposed Project.

Comment: The current EIS should be withdrawn and a supplemental EIS complying with NEPA/SEPA rules and guidelines must be circulated for comment. [LTR 176, CMT 8]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: The failure of the BPA and EFSEC to consider alternatives, including alternate locations and different configurations are fatal flaws in the DEIS. [LTR 176, CMT 8]
Response: The lead agencies believe that the EIS considers a reasonable range of alternatives and adequately describes these alternatives, consistent with the requirements of both SEPA and NEPA. Issues raised in these comments specific to alternatives considered but eliminated from detailed study in the EIS are addressed in other response to comments in this section.

Comment: Fourth, there is considerable discussion of the need for the project’s resources on a regional basis. See DEIS at 1-4 and 1-5. However, there are real questions as to need for this variable energy facility. At the outset, it appears that most wind energy is not, as indicated at page 1-4 of the DEIS, used or useful in the Northwest. As indicated in the April 12, 2010 submission of BPA to the Federal Energy Regulatory Commission (FERC) on their docket Docket No. RM1 0-11-000 regarding regulation of “variable energy resources” (VER) at page 2: The need to clearly define balancing authority roles and responsibilities is especially important to BPA, because approximately 80 percent of the almost 2,800 MW of wind generation currently on BPA’s system is exported to other balancing authorities, and BPA’s preference customers should not bear costs of integrating wind generation that is exported to serve load outside of BPA’s balancing authority. Thus the EIS must consider whether the WR project or other wind projects actually meet loads in the Northwest. In addition, as the BPA submission to FERC makes clear, it is necessary for balancing power to be available to meet loads when the wind does not blow. As noted by BPA in their comments on Docket No. RM1 0-11-000, at page 5, there are additional problems with balancing loads when wind energy resources are exported to California or to other sink authorities. These facilities might include increased reliance on hydro resources or peaking facilities such as gas turbine plants. The EIS should consider whether additions of a VER like WR will result in the need for other peaking facilities to balance loads and whether the addition of a VER like WR is consistent with meeting demand. [LTR 176, CMT 9]

Response: Please see response to Comment LTR 36, CMT 9 above.

Comment: [In reference to DEIS Section] 1.4, ALTERNATIVES ANALYSIS, [t]he Alternatives Analysis is limited to a No Action alternative. While the DEIS states that other locations, project sizes and project configurations were considered, it fails to identify these alternative locations or configurations, or adequately explain why they were not worthy of additional analysis. As described in more detail below, the off-site and on-site alternative analyses should be expanded to include in-depth descriptions of the criteria used to select the proposed site and the proposed project configuration, as well as a focused discussion about why other sites and project configurations were excluded from further review. [LTR 177, CMT 2]

Response: The lead agencies believe that the DEIS presented a reasonably thorough discussion of the consideration of alternatives for the proposed action, including why alternative locations were not being further studied. The reasons that the Applicant proposed its wind project at this particular location is explained in Sections 1.4.1 and 2.3 of the EIS. As discussed in these sections, a variety of factors were considered in evaluating whether alternative locations might be feasible. To further clarify turbine string site selection, six suitability requirements
were considered. They are as follows: lands owned by the Applicant or Broughton Lumber; within three miles of BPA transmission lines; outside of CRGNSA boundary; suitable terrain; road access; and contains at least 1,000 “suitable” land. Furthermore, “suitability” is described as follows:

- Low suitability properties: These are parcels that are within 3 miles of transmission lines, are outside the NSA boundary, have a terrain difference of between 200 and 500 feet, and have road access. These parcels are designated in yellow on the “Tract Suitability Analysis” map (see Figure G-1).
- Potentially suitable properties: These are parcels that are within 3 miles of transmission lines, are outside the NSA boundary, have a terrain difference of between 500 and 1,000 feet, and have road access. It should be noted that these parcels could be ruled out as being unsuitable based on other factors not assessed in this analysis, such as slope direction or parcel size. These parcels are designated in brown on the “Tract Suitability Analysis” map (see Figure G-1).
- Suitable properties: These are parcels that are within 3 miles of transmission lines, are outside the NSA boundary, have a terrain difference of between 500 and 1,000 feet, and has what appear to be better road access than properties identified as “potentially suitable”. These parcels are designated in dark pink on the “Tract Suitability Analysis” map (see Figure G-1).
- Highly suitable properties: These are parcels that are within 3 miles of transmission lines, are outside the NSA boundary, have terrain differences between 1000 and 2000 feet above surrounding terrain and contain the highest hills/ridgelines within the study area, and have good road access. These are the best possible locations within the study area for wind facility development. Of the analyzed parcels, only 1 parcel fell into this category. These parcels are designated in blue on the “Tract Suitability Analysis” map (see Figure G-1).

The proposed Whistling Ridge Energy Project site was identified by the Applicant for its location within the “highly suitable properties”. This site was then forwarded for further environmental analysis including wildlife surveys. Issues raised concerning alternative configurations for the proposed Project are addressed in other response to comments in this section.

Comment:  
[In reference to DEIS Section] 1.4.1, Proposed Action, [t]he second bulleted factor in this section indicates that the site must be large enough to accommodate enough wind turbines to produce a minimum of 70 MW of electricity. Because the wind does not blow at a constant rate, wind turbines rarely operate at 100% percent capacity. Accordingly, references to wind generating capacity should be expressed in nameplate generation capacity. [LTR 177, CMT 3]

Response:  The second bullet in Section 1.4.1 has been edited to reflect that the 70-MW reflects the minimum nameplate capacity generation.
Comment: The fourth bulleted factor in this section states: “The site has a long history of commercial logging and associated absence of native habitat, reducing or eliminating the need to clear additional forest land.” This and similar statements regarding the “absence of native habitat” are made in several places in the document (e.g., [DEIS Section] 3.4.1.1), and the statement is misleading. With the exception of the weeds identified at the site and disclosed elsewhere in the document, grass, forb, shrub, and tree species at the site are predominantly native. A more accurate statement would be that the site is heavily managed and manipulated and is not in a natural state, being maintained in a state of disclaimed and with monotypic forest stands. The affected environment description provided in Chapter 3 ([DEIS Sections] 3.4.1.1 and 3.4.1.2) is far more accurate. [LTR 177, CMT 4]

Response: The text in Section 1.4.1 (DEIS page 1-9) has been modified to reflect the fact that native species still occur in the Project Area even though it is heavily managed for timber production. The fourth bullet on page 1-9 of the DEIS has been revised to delete the phrase “and associated absence of native habitat” and now reads: “The site has a long history of commercial logging, reducing or eliminating the needs to clear additional forest land. Native species remain; however, the native habitat has been disturbed through commercial forestry activities.”

Comment: The final paragraph in this section states that the project would have a total nameplate capacity of “up to 75 MW.” The second bulleted factor in this section states that project’s minimum nameplate capacity is 70 MW. It is unclear how these two figures relate to one another. The project’s maximum and minimum nameplate generating capacity levels should be clearly identified and described in a single location. [LTR 177, CMT 5]

Response: Please see response to Comment LTR 177, CMT 3 above. Additionally, for more clarification, the 75-MW figure is the size of the Project that has been proposed by the Applicant. The 70-MW figure is the minimum capacity that the Applicant believes is necessary to have a financially viable project.
Figure G1. Project Siting for the Whistling Ridge Energy Project using Tract Suitability Analysis.
Comment:  [In reference to DEIS Section] 1.4.1.1, Wind Turbines, [t]he generating capacity should be referenced as nameplate capacity. This section should also clarify whether the size of the turbines will be consistent throughout the project or whether the size will vary from tower to tower. [LTR 177, CMT 6]

Response: The text in Sections 1.4.1.1 and 2.1.3.1 regarding wind turbines has been updated to reflect the nameplate generating capacity of the wind turbine models and the correlation between output and turbine size. The turbines throughout the Project would all be the same model, although height may vary in response to terrain. These clarifications have been incorporated into Section 2.1.3.1.

Comment:  [In reference to Section] 1.4.2, No Action Alternative, [t]his section states that the only circumstance the project will not be built is if the responsible agencies (BPA or EFSEC) withhold their authorization. There are a multitude of reasons why a proposed project may not be built. This statement is not accurate and should be removed from the FEIS. [LTR 177, CMT 7]

Response: It is acknowledged that many factors could result in the Project not being built, and nothing in the EIS is intended to indicate that project disapproval by the lead agencies - EFSEC and BPA - would be the only reason the Project may not be built. Nonetheless, for the purposes of defining the No Action alternative in the EIS, the key consideration is what the result would be if either or both of the lead agencies decide not to approve the proposed Project. Thus, the EIS references the No Action alternative in this manner.

Comment:  [In reference to DEIS Section] 1.4.3, Alternatives Considered But Eliminated From Detailed Study, [t]his section explains why the no action alternative was the only alternative analyzed. In doing so, it references a set of technical and economic requirements that purportedly eliminated all other potential project sites from consideration. None of the eliminated off-site locations, however, are identified, and the DEIS does not contain the underlying technical and economic data the Applicant used to eliminate the undisclosed sites from further consideration. At a minimum, the FEIS should include detailed information regarding the economic and technical data underlying the site selection criteria, as well as the locations of all potential alternative sites considered so that the decision to limit review to the No Action alternative can be independently verified. [LTR 177, CMT 8]

Response: Please see response to Comment LTR 22, CMT 2 above.

Comment:  [In reference to Section] 1.4.3.1, Alternative Project Locations, [t]he DEIS states that the Applicant applied the following criteria to determine whether alternative project locations were available for EIS review: adequate wind supply, applicant ownership of land, ability to operate wind turbines without impacting commercial timber operations, and proximity
to high voltage transmission lines. The DEIS analysis and discussion of the alternative location selection process is set forth in a single sentence: No other sites were identified that are under the ownership of the Applicant or as close to transmission infrastructure facilities. DEIS at p. 1-14. This summary analysis should be expanded to include a detailed description of the criteria used to select the project site, the location of the alternative sites that were considered, and discussion regarding why these alternative sites were ultimately eliminated from further consideration. [Footnote: Ideally, this discussion would include information sufficient to independently verify the decision to eliminate these alternative sites from further consideration. This would include the location of SDS holdings in Southern Washington and Northern Oregon, wind resources available in those areas, the location of transmission lines, economic parameters for the project, as well as economic information regarding the project’s interrelationship with timber harvesting activities.] [LTR 177, CMT 9]

Response: Please see response to Comment LTR 22, CMT 2 above.

Comment: [In reference to Section] 1.4.3.2, Larger or Smaller Generation Facility Size, [t]he FEIS should be expanded to address on-site alternatives that reduce the number of turbines and/or reconfigure the turbine strings. The purpose of the alternatives analysis is to explore whether the needs of the project can be accomplished through less environmentally impactful means. During the scoping hearings, the public and National Parks Service raised concerns regarding the project’s visual impacts, particularly regarding the location of Turbine String A. [Footnote: Turbine String A is also unique in that it contains the turbines in closest proximity to residential dwellings and is located on a parcel of land that is zoned FOR/AG 20, which would require issuance of a conditional use permit under Skamania County’s land use laws. See DEIS at p. 3-153.] This section asserts that the project must be reviewed as an “integrated whole” from which no piece may be eliminated and that if turbines are removed from the project design, “other locations must be found to replace those turbines to maintain the minimum necessary capacity.” These assertions are unsupported by analysis and appear to be inconsistent with the project description in both the Site Certification Application (SCA) and the DEIS. Both the SCA and the DEIS state that the project will have a total nameplate generating capacity of approximately 75 MW and will be comprised of up to 50 towers equipped with turbines with nameplate generating capacities ranging from 1.2 to 2.5 MW. [Footnote: The SCA at Section 2.3.3.1, for example, states that “[t]he project would consist of up to 50 wind turbines” and that each turbine would have a nameplate generating power of somewhere between 1.2- to 2.5 MW. (Emphasis added). The DEIS contains an identical description? See DEIS at § 1.4.1.1. Both the SCA and DEIS also state that the project must have a generating capacity of “up to 75 MW.” See SCA at §2.3.2 (Project Overview – “up to 75 MW”); DEIS at §II.1 (“minimum of 70 MW;” “up to 75 MW”).] Assuming that a 2 MW turbine is selected, the maximum generating capacity of 75 MW could be satisfied with the installation of 38 turbines (resulting in a reduction of 12 turbines). [Footnote: Recently permitted projects appear to be installing turbines with nameplate generation capacities of 2.0 MW or larger. The Desert Claim Wind Power Project, for example, will be installing 2 MW turbines. See Desert Claim Wind Power Project Final Supplemental EIS at 2-13. The recent expansion to the Wild Horse Wind Power Project also used 2.0 MW turbines.] If a 2.5 MW turbine is selected, the number of towers could be reduced to 30. Reducing the number of turbines without sacrificing nameplate generating capacity is not
merely hypothetical. The Kittitas Valley Wind Power Project recently reduced its total number of turbines from a maximum of 65 to a maximum of 52 turbines without any change in nameplate generating capacity. The FEIS should include a discussion regarding how the project may be reconfigured through the use of turbines with larger generating capacities. The FEIS should include information regarding the strength and viability of wind resources found throughout the site. This would include information gathered from the on-site meteorological tower regarding the strength, quality, direction and location of on-site wind resources. [LTR 177, CMT 10]

Response: Please see response to Comment LTR 22, CMT 5 above.

Comment: [In reference to Section 1.4.3.6, Alternative Access Roads, [p]rivate logging road CG 2930 should be subject to detailed review as an alternative access road. The original Site Certification Application proposed accessing the site using this route. On October 12, 2009, the Applicant submitted an amended application that abandoned the CG 2930 route in favor of the West Pit Road with the stated purpose of removing the entire project outside the CRGNSA boundary. See October 12, 2009 Letter from Whistling Ridge Energy Project to EFSEC re: Submittal of Amended Application 2009-01. Although removing this route from the project plan may dispose of certain regulatory hurdles, the West Pit Road is a longer route that traverses steeper terrain and will likely have a higher environmental impact than the CG 2930.5 [Footnote 5: Long sections of West Pit Road crosses land designated as a Class II landslide hazard area. See DEIS Figures 3.1-1, 3.1-4 and 3.11-2]. Accordingly, this CG 2930 should be evaluated as an alternative. 1.6 SUMMARY OF POTENTIAL PROJECT IMPACTS AND MITIGATION MEASURES Earth - p. 1-22 -Impact of Proposed Project: Much of the West Pit Road is located in a Class II Landslide Hazard Area. This section should summarize and address anticipated impacts, if any, related to Class II Landslide Hazard Areas. [LTR 177, CMT 12]

Response: Use of CG 2930 was evaluated in the original Application for Site Certification as “Route 2.” This route would have connected the site to Cook-Underwood Road via Kollock-Knapp Road, Scoggins Road and CG2930. CG2930 is a private logging road that crosses property owned by the Applicant and is currently used for commercial timber production and harvest. As described in Section 2.3.6 on Page 2-23 of the DEIS, use of Route 2 would require minor roadway improvements that would not directly impact any non-Project landowners. However, these roadway improvements would require construction within the National Scenic Area. Therefore, Route 2 was eliminated as a construction roadway access alternative purpose and need for proposed action, or clearly greater environmental impacts.

Comment: [In reference to Table 1-1 on Page 1-22 of the DEIS under “Air Quality: Impact of No Action Alternative”), [t]his section identifies impacts from construction of fossil fuel power plants as a potential impact under the no action alternative. There is nothing in the record establishing that proposed project is being built in lieu of fossil fuel powered plant or that its construction will reduce the number of fossil fuel powered generation facilities in the future. Indeed, intermittent nature of wind generated power may require the construction of fossil fuel facilities to provide a backup power source. [Footnote: The No Action Alternative analysis
appearing on p. 3-92 and in other section of the DEIS contains a more accurate description of the possible impacts if no action is taken: It is likely that the region’s power needs would be met through energy efficiency and conservation measures, existing power generation, or the development of new power generation. Base load demands would likely be filled through expansion of existing, or development of new thermal generation such as gas-fired combustion turbine technology. The impacts would depend on the type, location, and size of the facility proposed. [LTR 177, CMT 13]

Response: Comment acknowledged.

Comment: [In reference to Table 1-1 on Page 1-23 of the DEIS under “Biological Resources: Impact of No Action Alternative”], this section states that there “would likely be some mortality to birds and bats due to turbine collision and displacement.” This should be revised to state that operation of project “will result in mortality to some birds and bats...” [In reference to Table 1-1 on Page 1-24 of the DEIS under “Biological Resources: Design and Mitigation Measures], remove qualifier “extensive” from pre-project assessment of wildlife habitat conducted under WDFW Wind Power Guidelines. [In reference to Table 1-1 on Page 1-24 of the DEIS under “Biological Resources: Design and Mitigation Measures], a Technical Advisory Committee (TAC) is described, including a description of the stakeholders comprising this group. Because the overarching concern for biological resources is bird and bat mortality, a representative of the Audubon Society should be specified and included in the TAC. [Footnote: The TAC should also be expanded to include representatives from local public interest groups, including interveners Friends of the Columbia Gorge and Save Our Scenic Area.] [In reference to Table 1-1 on Page 1-25 of the DEIS under “Biological Resources: Design and Mitigation Measures], the post-construction avian mortality monitoring should include bat mortality monitoring as so little is known about bat species' composition and mortality risk at the site. The monitoring program should also analyze the accuracy of the pre-construction risk and mortality predictions. Because the project is being proposed in a new habitat type (forested) for Washington wind energy projects, and because so little is known about bat use of the site, bird and bat monitoring should be conducted for five (5) years, rather than the proposed two (2) years. [LTR 177, CMT 14]

Response: The text in Table 1-1 on DEIS page 1-24 has been revised to indicate that the proposed Project “would result in mortality to some birds and bats.” Additionally, the formation and membership of the TAC is subject to the Washington Department of Fish and Wildlife Wind Power Guidelines and would be governed by that agency. Both post-construction monitoring and the convening of a TAC to evaluate the mitigation and monitoring program were included as mitigation measures in the DEIS. See Section 3.4.3 Mitigation Measures.

Comment: [In reference to Section 1.6, Table 1-1], Visual Resources - p. 1-28 - Impact of Proposed Project: This section should clearly state that as proposed the project will have low to moderate visual impacts from key viewpoints, including key viewpoints within the CRGNSA. 1.7 SUMMARY OF UNAVOIDABLE ADVERSE IMPACTS This section should plainly identify and
summarize unavoidable adverse impacts. References to beneficial impacts should be removed. The description of unavoidable visual impacts (Table 1-2, p. 1-35) should be re-drafted to read as follows: This project will have unavoidable adverse visual impacts on the surrounding area. Visual impact analysis establishes that the project will have low to moderate visual impacts from key viewpoints, including viewpoints within the CRGNSA. [LTR 177, CMT 15]

Response: Table 1-2 references Section 3.9.5, which states that there would be some visual impact to surrounding areas where turbines were visible, but that these impacts would not be higher than low to moderate for most of the viewpoints examined.

Comment: [In reference to Section] 1.8, CUMULATIVE IMPACTS, [t]he discussions of existing development in section 1.8.1.1 and reasonably foreseeable future development in section 1.8.1.2 appear to be inconsistent. In section 1.8.1.1, the authors considered wind projects located 35 to 70 miles from the proposed project in their cumulative analysis. In section 1.8.1.2, however, the authors chose to disregard two proposed wind power projects (Juniper Canyon and Summit Ridge) because they are “too far away (generally more than 20 miles) from the Whistling Ridge Energy Project site to result in cumulative impacts.” Given that the cumulative analysis of existing impacts considered projects that were located 70 miles away, the analysis of cumulative impacts relating to reasonably foreseeable future development should apply similar criteria or include an explanation as to why different criteria were applied. [In reference to Section] 1.8.1, Projects Considered, [t]he cumulative impact section should discuss the intermittent nature of wind energy generation and the need for easily dispatchable hydro-electric or fossil fuel generating plants to meet demand when the wind is not blowing. [LTR 177, CMT 16]

Response: The cumulative impact analysis in Section 3.14 of the EIS considered the impacts on the environment from the Whistling Ridge Energy Project when added to both existing and reasonably foreseeable future projects. Section 3.14 of the EIS has been revised to reflect that the cumulative impact analysis includes existing and reasonably foreseeable future development generally within approximately 20 miles of the Project Area, but also existing and reasonably foreseeable wind projects that are farther than 20 miles from the Project Area for the purpose of assessing cumulative impacts to visual resources. In reference to the commenter’s concern regarding the intermittent nature of wind energy generation, please see Section 3.14.3.5, Fish Species in the Cumulative Impacts section of the DEIS. Currently, the Columbia River hydrosystem has sufficient reserve capacity to provide for fluctuations in wind generation.

Comment: We find that, in many areas, the present DEIS is completely insufficient and we urge that the NEPA/SEPA responsible officials prepare a supplemental DEIS. The following pages of written and charted comments, plus Exhibits, are intended to address some, but not all, of the deficiencies noted in the particular sections within the WRE DEIS that address Bats. In all cases, the deficiencies are explained. In most cases, particular remedies are suggested. Because no remedy is proposed by SOSA does not mean there should not be one implemented by the NEPA/SEPA responsible officials. [LTR 178, CMT 2]
Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Thank you for this opportunity to comment on the DEIS. SOSA trusts that the DFEIS and FEIS will provide facts and analysis on the issues raised herein. Science based studies require a statement of all assumptions made to design a study and collect, analyze, and interpret data. This is completely nonexistent in the DEIS and Appendices. [LTR 178, CMT 8]

Response: Please see response to Comment LTR 60, CMT 1 above.

Comment: [In reference to DEIS] Section 1.1.1 ...and there is a proven wind resource at the site. The use of the word “proven” should require substantiation. A review of government websites, like the National Renewable Energy Labs (NREL), found at windpowermaps.org, shows a wind rating for the WRE site as Marginal to Fair. They should provide met tower data, and the location of such. The only currently observed tower, from a public vantage point, is located on the highest predicted wind power location within the site, so additional met tower data should be provided at the lowest predicted locations as well. Given the Federal Investment Tax Credit, it is imperative that the public grants are used up on the best potential wind resources first, which this site is NOT (according to government predicted models). The Applicant should justify with supportably detail data to demonstrate otherwise. [see also comment at 1-9 (1.4.1)] Remedy - Wind Resource must be quantified by met tower data in multiple locations, and with wind direction in all THREE axes. Then these data must be compared to the alternative of wind resources in the Eastern portion of WA State. Wind power versus wind speeds must be discussed and compared. [LTR 178, CMT 32]

Response: The purpose of Section 1.1 of the EIS is to provide a brief introduction to Purpose and Need for the Action being proposed and is not intended to provide a comprehensive evaluation of the proposed Project details. There were several criteria applied to determine whether the Whistling Ridge Project or other alternatives were technically and economically feasible, and these criteria are discussed in Section 1.4.3 of the EIS. The criteria included the need for a “steady supply of robust wind power, and on a site on which construction can reasonably occur,” that “the Project must be located on land the Applicant owns and controls...,” and that “the Project must be located in proximity to existing high-voltage transmission lines.” While both Washington EFSEC and BPA need to respond to the applicable Applicant requests for authorizations and approvals regarding the proposed Project, neither have the jurisdictional authority to determine or require that the Applicant justify that the proposed Project is one of the “best potential wind resources.”

Comment: [In reference to DEIS] Section 1.3.2, [t]hose agencies may use this EIS in order to fulfill their NEPA or SEPA responsibilities. Providing that the final EIS is a fair, accurate, clear, and truthful document of the issues. Remedy - Issue a complete and accurate final EIS as the document used by Decision-makers in the Adjudicative process. [LTR 178, CMT 34]
Response: Consistent with SEPA and NEPA requirements, the lead agencies fully intend to produce an objective and reasonably thorough Final EIS for the proposed Project.

Comment: [In reference to] Section 1.4, two alternatives are evaluated in this EIS: the Proposed Action (authorizing construction and operation of the proposed Whistling Ridge Energy Project and associated components) and the No Action alternative. Proposed Action and No Action alone does not satisfy SEPA or NEPA requirements. The extent of available lands in the analysis should be determined by partnerships or contracts between Applicant and other parties/investors. Remedy - Reference SOSA comment letter addressing the topic specifically, in detail [LTR 178, CMT 35]

Response: The lead agencies believe that the EIS considers a reasonable range of alternatives and adequately describes these alternatives, consistent with the requirements of both SEPA and NEPA. Issues raised in these comments specific to alternatives considered but eliminated from detailed study in the EIS are addressed in other response to comments in this section.

Comment: [In reference to] Section 1.4.1, the site has a proven, robust wind resource - No legal data exists for A1-7, South of South BPA line, due to no conditional use permits issued by Skamania County, confirmed by Public Information Request, Drach to Skamania County Planning Dept. July 2010. Any Met tower Data in the Appendices? NREL wind power maps show the WRE site ranging from Marginal to Fair, as compared to typical Eastern WA projects listed as Fair to Good (www.windpowermaps.org) see also comment at 1-7 (1.3.1) Remedy - Wind Resource must be quantified by met tower data in multiple locations, and with wind direction in all THREE axes. Then these data must be compared to the alternative of wind resources in the Eastern portion of WA State. Wind power versus wind speeds must be discussed and compared. [LTR 178, CMT 36]

Response: A quantified comparison of the wind resource to other sites in the state with reasonably foreseeable wind development is not required by Washington EFSEC as a condition of the evaluation of the proposal, which is discussed in Section 1.2.1 of the EIS. Similarly, under BPA’s tariff, BPA offers transmission interconnection to the FCRTS on a first-come, first-served basis, as discussed in Section 1.2.2 of the EIS. It is the Applicant’s responsibility to determine the technical and financial feasibility of the proposed Project, with the most important consideration likely being the quality of the wind resource at the site.

Comment: [In reference to] Section 1.4.1.3, the Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line can cross underneath for this interconnection. The explanation of this requirement is unclear. Remedy - Provide a graphic of the substation site and locations of extra towers required. Identify if this is related to both potential substation locations. [LTR 178, CMT 37]
Response: The existing transmission lines that traverse the Project Area, the Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV and the North Bonneville-Midway 230-kV transmission lines, will have to be raised if this Project is approved. The reason being that the appropriate clearance will be needed to in order to make the interconnection loop-in to these lines from the proposed BPA substation that would be required for this proposed Project. The raising of the existing transmission lines would be needed only for the proposed BPA substation.

Comment: [In reference to Section 1.4.1.5], less than 5,000 gallons per day is anticipated for kitchen and bathroom use. No mention of quantity of water used to wash/clean Wind Turbine Blades and Towers. No mention of detergents involved in cleaning operation, nor potential release of chemicals into ground water from Turbine cleaning operations. Remedy - All uses of water at the site must be discussed, and the impacts of ALL water releases into the environment must be identified and addressed. i.e. washing the exterior of the Industrial Equipment. [LTR 178, CMT 38]

Response: It is not anticipated that washing or cleaning of the turbine blades or towers will be required due to the high level of precipitation in the area.

Comment: [In reference to] Section 1.4.2, [this [No Action] alternative would not help the state of Washington in achieving the renewable energy goals mandated by the state’s RPS. This is true for the ALL Alternatives, Action or No Action. There is no control over which state gets credit for the Renewable Energy from WRE, the power is sold to the highest bidder. EFSEC would need to condition WRE’s permit to sell its power only to Washington State entities, resulting in possible legal complications. Remedy - The EIS cannot claim that WARRPS are benefitted as a result of this Project as proposed. This must be removed as a discussed Benefit of the Project, unless an approved permit conditions the sale of WRE power ONLY to Washington State CONSUMERS, via utility contracts. [LTR 178, 39]

Response: Section 1.2.3.1 of the EIS discusses the Washington RPS primarily as an example of RPS legislation recently enacted by several western U.S. States, and since it is possible that a Washington state utility may seek in-state resources to fulfill RPS requirements. However, there is no certainty at this point as to what utility may purchase the output of the proposed facility.

Comment: [In reference to] Section 1.4.3.1, [and in proximity to existing high voltage transmission lines Proximity simply translates to a financial impact, which would be covered as a potential negative in a proposed alternative. Simply not including an alternative due to cost is not complying with SEPA and NEPA. It is up to the decision-makers to determine if those potential extra costs outweigh any potential benefits of the alternate location. Remedy - The DEIS should identify viable Alternatives by including projects in lower impact areas. In the case of a location distant from the GRID, presumably a larger MW capacity would be contemplated
to justify the extra cost, and these analyses should be made available to all to understand. [LTR 178, CMT 41]

**Response:** Please see response to Comment LTR 22, CMT 2 above.

**Comment:** [In reference to DEIS] Section 1.4.3.2, [t]hese objectives include providing a minimum level of generation to be attractive to utilities seeking to fulfill their RPS requirements... Documentation should support these claims as to the minimum level power generation, as well as the Entities (presumed Buyers) which have conditioned future potential agreements upon said minimum level of power generation, and the service area of said Entities. (i.e., WA, CA, AZ, etc.) Remedy - The EIS should include written statements from prospective Utilities which might purchase power from WRE, stating whatever conditions should exist for a Purchase Agreement to be negotiated at some future date. [LTR 178, CMT 42]

**Response:** The Applicant’s objectives reflect their analysis of their business case for the proposed Project. The minimum level of generation for utilities looking to fulfill RPS requirements is based on the Applicant’s assessment of other wind projects that have successfully entered purchase agreements with utilities seeking to meet RPS requirements. Information concerning the Applicant’s expected return on investment is considered confidential business data by the Applicant. Contrary to the commenter’s assertion, this proposed Project is a private project that, while it may have some incidental public benefits in the sense of helping develop renewables, is not being developed as a public project.

**Comment:** [In reference to] Section 1.4.3.2, [i]n order to provide this return, the Applicant has determined that the project must be capable of producing a minimum of 70 MW. Unsubstantiated claim, this is a private project operated for the public good, therefore financial analysis and justification is NOT exempt from review. (i.e. for WA RPS mandates) Remedy - The EIS should include written statements from prospective Utilities which might purchase power from WRE, stating whatever conditions should exist for a Purchase Agreement to be negotiated at some future date. [LTR 178, CMT 43]

**Response:** Please see response to Comment LTR 178, CMT 42 above.

**Comment:** [In reference to DEIS] Sections 1.4.3.6 2 and 2.3.6, Alternative Access Roads, Route 1: Ausplund Road to a private logging road vacated by Skamania County in 1987, which crosses private property (not owned by the Applicant) that is currently used for residential, agricultural orchards, and commercial timber production and harvest There is at least a 500’ portion of the old Ausplund Road that does not exist, it is overgrown with trees. (Picture attached) The portions of Ausplund Road Private are not available to the Applicant. Road building and improvements within the CRGNSA have been acknowledged by the Applicant as not allowed. This is simply NOT a viable Alternative, and therefore does not satisfy the SEPA
requirements. Applicant failed to include viable alternatives, like Little Buck Creek Road, which publicly connects with their land, and would reduce traffic congestion on Cook-Underwood Road, since it turns off early in the proposed route. Remedy - The EIS must remove Ausplund Road from consideration, and replace it with a known viable alternative, namely Little Buck Creek Road, or other real, existing route. [LTR 178, CMT 45]

Response: As explained in Section 2.3.6 (pages 2-22 and 2-23 of the DEIS), the use of Asplund Road (Route 1) has been eliminated from further consideration because use of this route would have required road improvements on private property not owned by the Applicant.

Comment: [In reference to] Sections 1.4.3.6 2 and 2.3.6, Alternative Access Roads, Route 2: Kollock-Knapp Road to Scoggins Road to a private logging road called the CG2930 road on County Assessor’s maps, which crosses property owned by the Applicant that is currently used for commercial timber production and harvest Kollack-Knapp Road was officially retracted by the Applicant in its Amended Application submitted around October 2009. By the Applicants own statements, it is NOT a viable Alternative, and therefore does not satisfy the SEPA requirements. Applicant failed to include viable alternatives, like Lacock-Kelchner Road, via Little Buck Creek Road, which publicly connects with their land, and would also reduce traffic congestion on Cook-Underwood Road, since it turns off early in the proposed route. Remedy - The EIS must remove Kollack-Knapp Road from consideration, and replace it with a known viable alternative, namely Lacock-Kelchner Road, or other real, existing route. [LTR 178, CMT 46]

Response: As stated in Section 2.3.6 (pages 2-22 and 2-23 of the DEIS), the use of Kollack-Knapp Road (Route 2) has been eliminated from further consideration. Therefore, no improvements to County roads within the Scenic Area would be required. See Section 1.4.1.6 for a description of the proposed haul route.

Comment: [In Table 1-1 on Page 1-22 of the DEIS under “Earth: Construction”), a detailed geotechnical investigation would be performed to identify any subsurface conditions. This is yet another example of a deficiency in the DEIS - no one can assess the environmental impact of massive recontouring, excavating and road building on steep slopes, until the geotechnical assessment is completed and included in the DEIS. This Study must be done, and included in the FEIS. Moderate to Severe changes to topography are likely, given the steep terrain and soil types. Prevailing winds would place the Turbines on the steepest Western slopes of the Ridge, and/or risk loss of critical performance if set too far to the leeward side of the Ridge. Economic viability could be at risk if geotechnical report finds problems. Please note that the economics appear marginal, so the risk level could be high. Remedy - The steep ridges of the proposed WRE project present significant geotechnical challenges that do not exist for projects placed in farming area. The EIS must include real and likely ground-displacing activities, the volumes of material to be moved, the locations of displaced material, the depths needed to secure
foundations, etc. if for no other reason than to ensure the Applicant that realistic construction costs do not render the project economically unviable. [LTR 178, CMT 47]

Response: As discussed in Section 2.1.2 of the EIS, final siting of the wind turbines and associated facilities would be done following completion of the EFSEC Site Certificate. Prior to this final siting process, as a condition of the Site Certificate and as discussed in Section 3.1.3, a detailed geotechnical investigation of the specific locations of all wind project elements would be conducted. If this investigation indicates the potential for slope instability at turbine sites or other project facilities such as access roads (including improvements to West Pit Road), these facilities will be redesigned or relocated to avoid this risk. As discussed in Section 2.1.3.7, all road improvements required for the proposed Project would be designed and constructed under the direction of a licensed engineer, in accordance with the Skamania County Private Road Guidelines and Development Assistance Manual. All county roads requiring improvements would be designed and constructed in accordance with the WSDOT Design Manual.

Comment: [In reference to Table 1-1 on page 1-23 of the DEIS under “Biological Resources: Impact of No Action Alternative”], potential Impacts from construction of fossil fuel power plants. Please clarify the language, as SOSA’s interpretation is that the Applicant would thus potentially pursue a fossil fuel (natural gas) plant at this site, if No Action on the Wind Plant was followed. One may already be being planned even if the Wind plant is permitted. Remedy - Clarify the statement by indicating if this is a general statement, or specific to the vicinity of the proposed WRE project. (i.e. within 10 mile radius) [LTR 178, CMT 48]

Response: There are no proposed plans for any fossil-fuel generation at the Project Area. The referenced comment above related to Table 1-1 has been modified to say “Other power generation facilities could be constructed and operated in the region to meet long-term needs for power, including other wind projects or generation using fossil fuels.” Additionally, see Section 3.4.2.2 for a discussion of the impacts of the No Action Alternative on Biological Resources. As stated on DEIS page 3-81, “Other power generation facilities could be constructed and operated in the region to meet long-term needs for power, including other wind projects or generation using fossil fuels.”

Comment: [In reference to Table 1-1 on page 1-23 of the DEIS under “Construction”], micrositing of turbines and associated facilities would allow sensitive resources discovered during construction to be avoided. Applicant states in DEIS that the micrositing corridor is very narrow along the ridge line due to steep slopes on both sides. Any discovery of sensitive resources, or even geologic hazards, could disrupt or preclude a major portion of the entire Project, thus placing it in financial jeopardy. Compared to Facilities cited in farm lands and grass/shrub/steppe topography, this site has almost no flexibility to adjust to problems discovered during construction. Remedy - No concrete remedy to suggest, and no pun intended. [LTR 178, CMT 49]
Response: The 650-foot width of the turbine corridor allows sufficient flexibility in siting individual wind turbines and access roads to avoid sensitive resources that may be discovered during construction.

Comment: [In reference to Table 1-1 on page 1-24 of the DEIS under “Operation”], [t]here would likely be some mortality to birds and bats, though not in sufficient quantities to affect population viability. This is a sweeping and dangerous generalization. PLUS, what constitutes a given species’ viability has NOT been defined anywhere in this DEIS. Such a subjective assertion does injustice to the scientific principles and integrity required in any EIS. The data is sufficient to clearly show greatly elevated bird and bat numbers compared to recent wind projects in Klickitat County, WA. And the actual mortalities far exceeded predicted mortalities at those sites. One should assume a similar trend for these Projects in close proximity. It is a great leap to go from predicting mortality to predicting a species’ viability. In this Project site, how many Goshawks can society loose? How many Townsend Big Eared Bats can society loose before they are non-viable? It really depends on who you ask. Rather than forcing the issue, society should first choose and deplete the sites for Wind Turbines where man has already developed – meaning – use up the nation’s farmland for wind energy before clear cutting the forest to do so. Remedy - The EIS should remand the Bat studies for completion again, using the mature technology of the Anabat 2 hardware, and Analook software, which is capable of identifying species of Bats, not just a threshold 35KHz between big and small bats. A significant discrepancy between the WEST 2008 and 2009 studies is the duplicative sensors and the filtered noise percentages, confirming the underlying assumptions between the two studies changed dramatically, but were not discussed. [LTR 178, CMT 50]

Response: Section 3.4.4, Unavoidable Adverse Impacts, has been revised to change the language regarding population viability (DEIS page 3-83). The second paragraph has been revised to read: “No population impacts are expected to birds through turbine collisions. Adequate information is not known on bat population sizes to determine whether population response would be anticipated.”

Comment: [In reference to DEIS] Section 1.6, Table 1-1, “Operation,” [t]urbine fires are possible, however...are extremely rare. This issue is serious, because even if the potential occurrence is low, the risk to ALL residents of Underwood’s lives and properties is extremely high. Any standardized risk assessment model uses the product of “occurrence” and “severity of occurrence” to assess risk. (for example - FMEA - Failure Modes Effects Analysis) It appears the Applicant wants to oversimplify this issue by not considering the issue in a proper manner. This Project is proposed in a Forest environment: an ignitable fuel source in close proximity to the Turbines. There are areas in the Project site that cannot be clearcut to reduce the fire risk - namely the western slopes where identified slide hazards exist, and there are unlogged lands on the western slopes owned by Washington state DNR. (between North BPA line and South BPA line ~1 mile?) The statement about being extremely rare is based upon typical wind farm topography and elevation. The steep terrain, and unconfirmed meteorological data, combined with elevated fuel loads compared to the norm, may likely result in a catastrophic wildfire event.
Without comparable scenarios, existing data should not be relied on. In the alternative, the Applicant could continue its current site condition by maintaining the massive clearcutting already undertaken throughout most of the Project area. This, however, would result in the effective “permanent” removal of the “forest” ecosystem, and those environmental impacts would then need to be addressed, and presumably mitigated. Again, cost is a major part of the equation, and this Applicant has already said they are on the edge of viability. One can insure property, but not lives. Remedy - The DEIS should consider the Environmental Impacts of the project, as if the entire site were removed from Forestry altogether, and the ground maintained with minimal fuel loads. [LTR 178, CMT 52]

Response: Section 3.6 of the EIS describes the Project Area and the potential fire impacts from the proposed Project but does not specifically describe response measures for each possible scenario. There are numerous precautions that will be included in the Fire Protection and Prevention Plan that would be developed by the Applicant for EFSEC approval, as mentioned in Section 3.6.3, but this plan would not be prepared unless the decision is made to build the proposed Project. The Certificate Holder will be required to develop and implement an operations phase Fire Control Plan in coordination with state and local agencies to minimize risk of accidental fire during operation and to ensure effective response to any fire that does occur. The Site Certification Agreement will include a provision that no later than sixty (60) days prior to the beginning of Commercial Operation, the Certificate Holder shall submit the Fire Control Plan to EFSEC for review and approval. The fire protection plan and implementation of additional fire precautions will also be coordinated with the Skamania County Fire Marshall and DNR in response to fire conditions in the Project Area.

Comment: [In reference to DEIS Section 1.6, Table 1-1, Visual Resources: Operation. At a distance beyond 2500 feet, shadow flicker is considered. Even if shadow flicker were a proven impact, none of the planned turbines are within 2500 feet of existing residences. The statement fails to identify a permitted residential structure, applied well prior to WRE’s Application, that is within 2000 feet of the proposed Facility. Remedy - Consider adding the following language to the end of the existing sentence: “... and the permitted residence at 2000 feet could be mitigated by appropriate vegetative screening placed by the Applicant on its land, adjacent to the affected residence.” Since this 80 acres of land, in the Project Site, was just logged in June/July 2010, new vegetation will need to be planted if this measure is deemed appropriate. [LTR 178, CMT 53]

Response: Section 3.6.2.1 discusses the use of operational controls that could be implemented to reduce shadow flicker. This includes controlling turbine speed or orientation during specific periods.

Comment: [In reference to DEIS Section 1.6, Table 1-1, “Operation,” EMF from the project will be lower than those of many common household appliances and would have no health or safety impacts. Please provide/include data to support this assertion. Not only Electromagnetic Fields (EMF) should be included, but also stray electrical voltage produced during normal operations, during lightning storms, and especially power must be dumped into
the ground during temporary grid overload conditions. One of SOSA’s members, Tom Drach, and his family live at a residence roughly 2500 feet from proposed Turbines. There is strong evidence to suggest such stray electricity would pose a safety impact, due to potential failure of Electrical services and systems dependent upon such. For example, Ground-Fault Electrical Devices required by WA Code. The geology of this area is known to contain faults and fractures, which would tend to carry electrical energy much, much further than in an homogenous isotropic type soils, which is likely assumed in the Applicant’s analysis. Remedy - Any proposed permit should include provisions for nearby residents to fully remedy issues related to stray voltage and stray electro-magnetic energy, with the entire cost burden placed on the Applicant. [LTR 178, CMT 54]

Response: EMF readings for transmission lines and common household appliances are shown in Table 3.6.4. Readings for transmission and distribution lines are shown to be lower than some common household appliances. The source of this information is the National Institute of Environmental Health Sciences. If the proposed Project were to be approved, EFSEC would provide plan review and inspection of construction activities for all Project buildings, structures, underground and overhead electrical lines, sanitary waste water discharge systems, and other Project facilities to ensure compliance with the Site Certificate Agreement. Construction would be in accordance with the approved design and construction plans, the IBC (International Building Code) and UBC (Uniform Building Code of 1997) and other relevant regulations. EFSEC may contract with Skamania County to provide these services. If Skamania County is unable to provide timely review and inspection services, EFSEC would coordinate with the County on the selection of other appropriate agency or firms to provide such services. Any additional information regarding EMF and BPA’s transmission lines can be found on BPA’s website at: http://transmission.bpa.gov/LanCom/Safety_Around_Power_Lines/emf.cfm.

Comment: [In reference to DEIS Section] 1.6, Table 1-1, Visual Resources: Operation. The turbines would be visible from some viewpoints, including some within the CRGNSA. This project has the potential to create low to moderate levels of visual impact at key viewpoints. The statements made here should be quantified, or terminology defined more precisely. The wording tends to minimize the issue, and “low to moderate” should have some reference scale for decision-makers to know how to gage severity on a commonly understood basis. Such subjectivity, especially in a summary, can lead to erroneous interpretations. (Decision makers with limited time to review may rely on the Summary to inform them as to the critical issues involved) Remedy - Quantify the visual impacts in table format for each Key Viewing Area within the CRGNSA, as well as other noteworthy points in view of the proposed project. Remove subjectivity by implementing an intuitive, commonly understood reference scheme. [LTR 178, CMT 55]

Response: “Low” and “moderate” impacts were defined in Section 3.9.3.1 on DEIS page 3-175. Additional discussion on the definition of these terms in the summary would not add clarity to the document, but would be repetitious.
**Comment:**  [In reference to DEIS] Section 1.6, Table 1-1, Public Services and Utilities: Operation, [t]he project’s assessed value could be as much as $87.5 million, and this would generate approximately $800,000 per year in tax distributions..... AND Table 1.1 Socioeconomics: Operation, [t]he proposed project would have an estimated value of $87.5 million, which would represent an increase of 6.5% in assessed value in the County. At current tax rates, the increase in property tax revenue to the County would be $731,500 annually. The statement in Table 1.1 must accurately reflect the likely financial benefit, rather than the theoretical maximum, so the decision makers can weigh the true benefit appropriately. WRE’s number grossly exaggerates the tax benefit to municipal, County, and local jurisdictions. The SEPA responsible official should contact Mr. Gabe Spencer, Skamania County Assessor, to confirm these numbers are not accurate. A member of SOSA had a conversation with Mr. Spencer on June 24, 2010, and left with the following understanding: Scenario 1, Project remains privately owned during operation then Assessed Value will be a negotiated 10 year average value which will remain constant for the first 10 years to offer more uniform cash flow for the County Budget versus Straight Line or MACRS depreciation methods. (ref Klickitat County model) Furthermore, by complex Budget laws, residents in the Underwood District would otherwise be potentially subject to the shortfall in revenue as depreciation mounted from the Project. (Surely this would be a strong negative for Underwood Community) So, under the 10 year average scenario, WRE’s tax payments would be closer to $350,000 per year, NOT $800,000. Scenario 2, The Project is acquired by a WA state recognized public utility, like PSE. The tax for this is not determined by local real tax law, but by a complex formula within the State Dept. of Revenue (WDOR). According to Ms. Chris Miller, Columbia County, WA Assessor, their Projects which have fallen under WDOR jurisdiction have only provided their County with approximately one-third (33%) of the revenue claimed by the Applicant using the same assumptions as WRE has here. So this value would be ~$266,000, NOT $800,000 per year. Remedy - The SEPA Responsible Official should consult with the Skamania County Assessor to determine the potential financial outcomes, and report as such in the EIS. The only data provided in the EIS is clearly based on the Applicants information to the SEPA responsible official, and does not reflect the two MOST likely scenarios. If the present DEIS scenario is maintained, it should reflect a declining tax payment based on equipment depreciation, and the real, long-term burden on the Underwood residents thru increased levy rates. [LTR 178, CMT 56]

**Response:**  Table 1-1 serves only as a summation of the environmental consequences that are expected to occur from the Proposed Action. Section 3.13, Socioeconomics, gives more information pertaining to the expected economic benefits to Skamania County. Specifically, Section 3.13.1.4, Public Finance and Fiscal Conditions, discusses expected tax revenue benefits to Skamania County in more detail. Furthermore, the expected economic impacts to Skamania County are discussed in Section 3.13.2, Impacts.

**Comment:**  [In reference to DEIS] Section 1.6, Table 1-1, “Public Services and Utilities,” “Operation: Fire Protection,” [f]or the Operation phase of the project, nowhere is there listed an intent to construct and maintain a water reservoir or storage capacity for on-site fire suppression of the Project site if a Turbine fire failed to be contained. Given the fuel loads present, and lack of water, any Fire Protection and Prevention Plan should be required to
include a storage reservoir suitable for use by both land-based equipment and fire-suppression helicopters. Due to steep terrain, the turbulent updrafts present along the ridgeline would limit the ability of fixed-wing aircraft to assist in fire suppression at key areas of the Project site. Simply complying with existing DNR regulations, as the Applicant suggests, does not suffice, for the DNR statutes could not have contemplated the operation of Industrial-grade mechanical and electrical equipment of this magnitude operating in a forested environment, and 24 hours a day, a good portion of which without human observation. Remedy - Include the requirement for, and analyze the impacts of, establishing a fire suppression reservoir, or holding tanks to combat runaway fires. [LTR 178, CMT 57]

Response: Please see response to Comment LTR 178, CMT 52 above.

Comment: [In reference to DEIS] Section 1.6, Table 1-1, Public Services and Utilities: Operation, the project would employ eight to nine employees; most would be hired from the local area. Please also include the number of Full-Time Equivalences (FTE’s) that these eight to nine employees would provide. This is the best way to clarify for the decision-makers how much benefit is realized thru Project operation. Remedy - Include Full-Time Equivalents (FTE’s) as part of the description of Operations Personnel. [LTR 178, CMT 58]

Response: Full-time equivalent (FTE) is utilized to measure a worker’s involvement in a project. An FTE of 1.0 means that the person is equivalent to a full-time worker; while an FTE of 0.5 means that the worker is only employed half-time. Typically, different scales are used to calibrate this number, depending on the type of institution (schools, industry, research) and scope of the report (personnel cost, productivity). Furthermore, the Government Accountability Office (GAO) defines FTE as the number of total hours worked divided by the maximum number of compensable hours in a work year as defined by law. For example, if the work year is defined as 2,080 hours, then one worker occupying a paid full time job all year would consume 1.0 FTE. Two employees working for 1,040 hours each would consume 1.0 FTE between the two of them (where each worker would be working only half-time). Section 3.13.2.1, Impacts of the Proposed Action, presents this information in yet another way. The estimated annual labor cost of these 8-9 workers is expected to range from $167,000 to $188,000 per employee. Further discussion of these estimations and methodologies for predicting labor costs can be seen in Section 3.12.3 Mitigation Measures.

Comment: [In Section 1-6, Table 1-1, under] “Socioeconomics: Operation,” [b]ased on a review of available studies, operation of the project is not expected to create adverse impact to property values. Data on this subject is limited for a number of reasons. Significant differences in underlying assumptions hold for the WRE project. As such, “... a Property Value Guarantee (PVG) should be required of the developer. A State[-]controlled fund or developer bond should be required to guarantee no undue delay in PVG payment(s) to legitimately affected homeowners, and/or to buy out homeowners located within 2-miles of any turbines if they elect to relocate away from the turbine project(s) and cannot sell for the pre-project market value of their properties. Such a guarantee is nominal in cost, relative to total project costs, and are used
to condition high impact land use approvals such as landfills and even limestone quarries, as well as other wind energy developments." References - Exhibit 2F, attached as separate PDF file due to size. Citation from McCann Appraisal LLC Property Value Report to Adams County Board, IL, June 8, 2010, copy included in Appendix [website added here: http://nowindfarms.com/blog/testimony-of-michael-mccann-on-property-value-impacts-in-adams-county-il/#]. This report includes several other recommendations, appropriate for conditioning the WRE Application, to protect residents if Developer claims are later determined to be incorrect. Remedy - The EIS should include, in the Appendix, a reference Template on a Property Value Guarantee, which generally outlines the structure and authority of such a Guaranteed by the Applicant. Decision-makers should have a clear idea of the likely protections which would be result, in the event they choose to implement such, as part of any conditioning of a project permit. [LTR 178, CMT 59]

Response: RCW 80.50.100 mentions the following: “The council shall include conditions in the draft certification agreement to implement the provisions of this chapter, including, but not limited to, conditions to protect state or local governmental or community interests affected by the construction or operation of the energy facility, and conditions designed to recognize the purpose of laws or ordinances, or rules or regulations promulgated thereunder, that are preempted or superseded pursuant to RCW 80.50.110 as now or hereafter amended. However, RCW 80.50.100 only addresses “community interests” which does not include personal property values. Therefore, discussions related to Property Value Guarantees are not handled by EFSEC or BPA and are outside the scope of this EIS.

Comment: [In reference to DEIS] Section 1.7, Table 1-2, Public Health and Safety, unavoidable adverse impacts to environmental health are anticipated to be minimal. Please amend or clarify this statement, as it OMITS any reference to Public Safety. (The Element of the Environment heading is: Public Health and Safety) Plus, should one assume that the word “environmental” used in the DEIS is synonymous with “Public”? Remedy - Please correct the wording to address Public Health and Safety, rather than environmental health. [LTR 178, CMT 60]

Response: The text in Table 1-2 of the DEIS, Public Health and Safety, has been updated to clarify the impacts of the potential Project to Public Health and Safety. Similarly, the heading for the row in Table 1-1 on page 1-25 of the DEIS has been changed from “Environmental Health” to “Public Health and Safety” for consistency. No changes to the description of impacts in the second column of Table 1-1 of the DEIS have been made because each of the impacts described are understood to be potential impacts to “Public Health and Safety,” and are described in more detail in Section 3.6 of the EIS.

Comment: [In reference to] Table 1-2, Noise: …and operation noise is predicted to be less than the nighttime threshold of 50 dBA Leq, per Washington State and Skamania County regulations. Short-term noise impacts during construction is exempt so long as it occurs during daytime hours, and operation noise is predicted to be less than the nighttime threshold of 50 dBA
Leq per Washington State and Skamania County regulations. Even though Oregon has much more progressive laws on noise and setbacks, the minimum legal standard in WA is the (woefully inadequate) Washington Administrative Code (WAC 173-60). WA noise standards. The public welfare is better served by, and EFSEC is encouraged to so condition, the Environmental Protection Agency Guidelines: In April 1973, the local EPA Region X office published a document titled, “Environmental Impact Statement Guidelines.” This document discusses potential impacts from noise increases in terms of expected community response to the introduced noise source. This regional EPA guideline document suggests the following potential community responses to ranges of noise increases: Up to 5 dBA increase – few complaints if gradual increase; 5 to 10 dBA increase – more complaints, especially if conflict with sleeping hours; Over 10 dBA increase – substantial number of complaints According to the EPA Region X document, generally no mitigation is required if the increase is less than 5 dBA. Some mitigation should be considered for increases of 5 to 10 dBA. Increases greater than 10 dBA would be considered serious and would warrant close attention. Reference - Kittitas Desert Claim 2004 FEIS at 3-192 : Environmental Protection Agency Guidelines All Verbal and Written comments submitted by Keith Brown and/or Teresa Robbins for the WRE DEIS, are incorporated by reference here by SOSA. Remedy - Consider requiring the Applicant to follow the document titled, “Environmental Impact Statement Guidelines,” which would limit noise to 10 dBA over typical background levels (25 dBA nighttime, 35 dBA daytime, typ. for rural areas) Thus making the condition for noise not to exceed 35 dBA at night, and 45 dBA during the day. The WAC code did not contemplate noise sources from Wind Turbines, and their proximity to residential use. Furthermore, SOSA incorporates the recommendations of Keith Brown and Teresa Robbins by reference, regarding all the aspects of the noise subject. [LTR 178, CMT 61]

Response: In the absence of statutory noise limits, such as regulations and ordinances, for a project vicinity or jurisdiction, the acoustical expert would draw from practical experience, refer to appropriate standards, and use professional judgment or opinion to develop appropriate acoustical guidance criteria that may be used to assess noise impacts. However, for this Project vicinity, there is existing State and County regulation regarding acceptable noise levels, and they are clearly defined as absolute criteria. The mentioned EPA guidelines are only guidance, and their suggested relative-type criteria can be complicated to implement for determining impact assessment due to the nature of ambient environmental noise: it is subject to variance from a number of factors including seasonal presence of noisy wildlife (frogs, insects, migratory birds, etc.), climate (temperature, humidity), ground wind speed, levels of outdoor human activities (within a community or at an individual property), surface traffic, aviation over-flights, seasonal HVAC usage (air conditioners during the summer months) and precipitation (rainfall on roofs, road surfaces, etc.).

Comment: General Comment on DEIS - Certain claims by the Applicant can neither be substantiated with certainty or refuted with certainty. In these cases, the Council should neither consider a claim to be a benefit or a detriment to the proposed Project. For example, Global warming, reduction in CO2 emissions, as supported by several scientific papers concluding that the “jury is still out” on some of these issues. Remedy - The EFSEC Council should consider these types of claims as neither a significant benefit or a significant detriment to the proposed Project. [LTR 178, CMT 135]
Response: EFSEC will consider the reasonableness of expected Project benefits and detriments in conjunction with the broad interests of the public as part of its recommendation to the Governor concerning the proposed Project.

Comment: General Comment on DEIS - Applicant must provide met data and “wind power” analysis (confidentially if needed) to EFSEC Council to justify why this site is sooooo much better that others, that it could justify or warrant consideration in light of all the issues against. Wind Power is defined as the integral of wind “energy” with time. This is commonly approximated as a function of average wind speed spanned out over a long time period. One must note that the calculated wind speeds (or power) just north of the north BPA line are a maximum for the project site, and the average for the site, as a whole, would be considerably less. Remedy - Financial justification for the Project needs to be disclosed and verified. [LTR 178, CMT 139]

Response: The purpose of the EIS that has been prepared is to evaluate the potential environmental impacts that could occur from the lead agencies’ actions concerning the proposed Project, not to require financial or resource justification for the proposed Project itself. In other words, neither SEPA nor NEPA require that an EIS prove or validate the applicant’s business case for its proposal.

Comment: General Comment on DEIS - It appears that many general and specific issues raised in the Scoping Report are not addressed, or not adequately addressed. To ensure the integrity of the Scoping Process, SOSA recommends the DEIS or “FDEIS” include a “Response Matrix” which would indicate the location(s) within the DEIS where the response, rebuttal, or otherwise answer to EACH scoping comment can be found. Remedy - Close the loop with the public comments by indicating responses in a “Response Matrix” as described to the left. [LTR 178, CMT 140]

Response: Please see response to Comment LTR 119, CMT 2 above.

Comment: General Comment on DEIS - Issues raised in the Scoping Process, under the Category of “Documents” (Issue Code “DX”), are not broken down in any detail. Lack of categorization of the individual documents, and subjects within, could have led to an important issue not being addressed. As part of the “Results Matrix” comment above, any matter raised in the “DX” issue code should be re categorized separably into the other Categories, and likewise noted where these issues are addressed in the DEIS. [LTR 178, CMT 141]

Response: Please see response to Comment LTR 119, CMT 2 above.
Comment: Furthermore, a supplementary DEIS or a new DEIS should be issued and public comment provided. [LTR 178, CMT 141]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: In reference to Exhibit 21, Page 1 - Pink Color Routes are the non-viable Alternate Routes identified in the DEIS. (at 1-16) Ausplund Road is NOT a possible alternative, given new road building within the NSA would be required, which the Applicant has acknowledged is not allowed for this use within the NSA. Pictures of the now overgrown portion of Ausplund road is shown on following pages. DEIS states in 1.4.3.6 (at 1-16) that both Alternatives have been eliminated as an alternative due to road construction requirements within the NSA. As such, the DEIS is deficient in that no Construction Roadway alternatives are identified or considered. SOSA has identified two alternatives - namely Schoolhouse to Little Buck Creek Road, and Lalock-Kelchner Roads, both of which will take traffic out of the NSA and allow the Applicant to build roads on property which it ALREADY owns, all the way to the proposed Project site. [LTR 178, CMT 143]

Response: The Applicant has evaluated numerous alternative access roads and believes that the currently proposed access route described in Section 1.4.1.6 is the best option.

Comment: We find that, in many areas, the present DEIS is completely insufficient and we urge that the NEPA/SEPA responsible officials prepare a supplemental DEIS. [LTR 178, CMT 146]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: The DEIS is so deficient that it cannot be used as the basis for a decision on the project. The proposed project should be denied outright, but if it is to be given further consideration, a supplemental or revised DEIS is required. [LTR 179, CMT 5]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Unfortunately, this Draft Environmental Impact Statement fails to take the hard look required by NEPA and SEPA. The DEIS is fundamentally flawed because it improperly narrows the scope of study, ignores and trivializes the impacts of the project, ignores or summarily dismisses detailed comments from the public and expert agencies, and was largely drafted and/or influenced by the applicant and the applicant’s consultants behind closed doors and is therefore extremely biased in favor of the project. [LTR 179, CMT 5]

Response: Please see response to Comment LTR 60, CMT 1 above.
Comment: The National Environmental Policy Act. A major purpose of the National Environmental Policy Act ("NEPA") is to ensure that federal agencies conduct fully informed environmental decision-making. NEPA promotes its sweeping commitment to "prevent or eliminate damage to the environment and biosphere" by focusing the attention of federal decision makers and the public on the environmental and other impacts of proposed agency action. 42 U.S.C. § 4321. By focusing agency attention on the environmental and socioeconomic impacts of a proposed action, NEPA ensures that the agency will not act on incomplete information, only to regret its decision once finalized. See Robertson v. Methow Valley Citizens Council, 490 U.S. 332, 349 (1989). To that end, “[t]he sweep of NEPA is extraordinarily broad, compelling consideration of any and all types of environmental impacts of federal action.” Calvert Cliffs’ Coordinating Comm. v. U.S. Atomic Energy Comm’n, 449 F.2d 1109, 1122 (D.C. Cir. 1971). An agency must “take the initiative of considering environmental values at every distinctive and comprehensive stage of the process.” Id. at 1111. [LTR 179, CMT 11]

Response: The objectives and requirements of NEPA and SEPA are noted. The lead agencies believe that all applicable NEPA and SEPA requirements have been met.

Comment: The State Environmental Policy Act. The Washington State Environmental Policy Act ("SEPA") applies to state and local governmental actions and decisions. SEPA’s general purpose is to require consideration of environmental factors at the earliest possible stage in order to allow decisions to be based on a complete disclosure of environmental consequences. See Stempel v. Dept. of Water Resources v. City of Kirkland, 82 Wn. 2d. 109, 118 (1973). Agencies are required to engage in an open and public study of environmental impacts at the earliest possible time. RCW § 43.21C.030(b); see also WAC § 197-11-300. Agencies must assess the likely cumulative, direct, indirect, short-term, and long-term impacts to the environment. WAC 197-11-030(2)(b), (2)(g); see also State Environmental Policy Act Handbook (SEPA Handbook) at 2 (2003). Agencies must also evaluate alternatives and mitigation measures. WAC 197-11-055(2)(c); see also SEPA Handbook at 2. Agencies “shall not limit” consideration only to impacts within the boundaries of the agencies’ jurisdiction. WAC 197-11-060(4). For projects with likely significant impacts, environmental impact statements are required to ensure that government agencies and interested citizens have an opportunity to thoroughly review environmental impacts of proposed actions at the earliest possible stage; the agency must use the EIS in planning actions and making decisions. WAC 197-11-400(4). “The primary purpose of an environmental impact statement is to ensure that SEPA’s policies are an integral part of the ongoing programs and actions of state and local government.” WAC 197-11-400(1). The EIS must be impartial and must inform decision makers of alternatives and mitigation measures that avoid or minimize impacts of a proposed action. WAC 197-11-400(2). The EIS must not merely rationalize a predetermined outcome. WAC 197-11-402(10). (“EISs shall serve as the means of assessing the environmental impact of proposed agency action, rather than justifying decisions already made.”) Rather, the EIS must include sufficient objective analysis to actually inform the agency’s decision making process. The EIS must be completed early enough to serve as a practical contribution to the decision making process. WAC 197-11-406 (“The statement shall be prepared early enough so it can serve practically as an important contribution to the decision making process and will not be used to rationalize or justify decisions already made.”); see also King County v. Boundary Review Board, 122 Wn.2d 648, 666, 860 P.2d 1024 (1993); Barrie v.
Kitsap County, 93 Wn.2d 843, 854, 613 P.2d 1148 (1980); Mentor v. Kitsap County, 22 Wn.App. 285, 291, 588 P.2d 1226 (1978). For projects with potentially significant or serious impacts, SEPA requires the same hard look that NEPA does. “The level of detail shall be commensurate with the importance of the impact,” and in the face of any scientific uncertainty, the EIS must disclose the uncertainty and analyze the worst case scenario and the likelihood of its occurrence. WAC 197-11-402(2) and 197-11-080(2). [LTR 179, CMT 12]

Response: Please see response to Comment LTR 179, CMT 11 above.

Comment: The DEIS is Improperly Designed so that the Applicant’s Private Economic Interests Unlawfully Dictate the Purpose, Need, Alternatives, and Eventual Outcome for the Proposed Action. A. The Purpose and Need Statement in the DEIS is Being Improperly Driven by the Applicant’s Private Economic Interests. NEPA requires federal agencies to “rigorously explore and objectively evaluate all reasonable alternatives” to a proposed action. 40 C.F.R. § 1502.14(a). In order to do so, the agency must first reasonably and objectively define the purpose and need of a proposed action. See Simmons v. United States Army Corps of Eng’rs, 120 F.3d 664, 666 (7th Cir. 1997) (citing Citizens Against Burlington, Inc. v. Busey, 938 F.2d 190, 195–96 (D.C. Cir. 1991)). The chosen statement of purpose and need effectively dictates the range of alternatives evaluate in an EIS. Id. “[A]n agency cannot define its objectives in unreasonably narrow terms.” City of Carmel-By-The-Sea v. United States Dep’t of Transp., 123 F. 3d 1142, 155 (9th Cir. 1997). “An agency may not define the objectives of its action in terms so unreasonably narrow that only one alternative... would accomplish the goals of the agency’s action, and the EIS would become a foreordained formality. Nat’l Parks & Conservation Ass’n v. Bureau of Land Mgmt., 606 F.3d 1058, 1070 (9th Cir. 2010). Moreover, an agency may not allow the economic needs and goals of a private applicant to define the purpose and need, and hence the inevitable outcome, of an EIS. Id. Unfortunately, that is exactly what is happening with this EIS. [LTR 179, CMT 13]

Response: EFSEC and BPA have identified their respective need for action in a manner entirely consistent with SEPA and NEPA. As discussed in Section 1.2.1 of the EIS, EFSEC’s need for action is to respond to an application by WRE for a site certificate. As discussed in Section 1.2.2 of the EIS, BPA’s need for action is to respond to WRE’s request for an interconnection of its proposed Project to the Federal Columbia River Transmission System (FCRTS). Each agency also has separate purposes (i.e., objectives) that it will bear in mind and attempt to meet in reviewing and making a decision on the Project. Given the agencies’ need for action in this case (i.e., to approve or deny an application and request), the range of alternatives considered in detail in the EIS is not unreasonable. In addition, the agencies considered a number of other alternatives but eliminated those alternatives from detailed study in the EIS, as discussed in Section 2.3.

Comment: The DEIS lists the applicant’s “needs,” including the “business needs of the applicant” (such as “diversifying the holdings” of the Applicant) as stated needs for the project, and lists no agency-defined objectives or needs other than complying with applicable laws. The
DEIS fails to even acknowledge that the agencies have no obligation or responsibility whatsoever to meet the applicant’s needs or desires. As a result, the Applicant-identified needs are defining and driving the characteristics of this project and the alternatives thereto. This approach is inappropriate and unlawful. [LTR 179, CMT 14]

Response: Please see response to Comment LTR 179, CMT 13 above.

Comment: Interestingly, some of the Applicant-identified needs are suspect. For instance, the Applicant identifies a need for utilities in Washington State to provide more alternative energy to their customers. DEIS at 1-4–1-6. But nowhere has the Applicant specified or publicly committed to sell the electricity from this project within Washington State. As it stands, well over half of all the wind energy produced in Washington and Oregon is currently being sent to California. If a similar fate occurs with the electricity from the Whistling Ridge project, then the Washington state requirements for alternative energy are wholly irrelevant to the project. The applicant cannot have it both ways. It cannot assert that meeting Washington state renewable portfolio standards is a need for the project, and yet refuse to commit energy from this project to remain in Washington state. [LTR 179, CMT 15]

Response: Please see response to Comment LTR 178, CMT 39 above.

Comment: The DEIS repeatedly states or implies that the project would reliably produce between 70 MW and 75 MW of energy. See, e.g., DEIS at [Pages] 1-9, 3-90, 3-271. The DEIS significantly overvalues the generating potential of the project. Wind energy facilities cannot continually generate energy at their rated capacity. Generally, wind energy facilities generate energy at 30% of capacity. So for this project, the actual energy output would be only 21 MW. Every assertion or implication in the DEIS that the Whistling Ridge project would produce 70 or 75 MW of energy must be corrected to reflect the likely actual production of the facility. This correction must also be reflected in the purported need to produce at least 70 MW of energy for the project to be marketable. In any event, the facility would likely deliver 21 MW of energy to the grid. [LTR 179, CMT 16]

Response: The commenter is referring to the distinction between the total capacity of a generator (expressed in terms of megawatts, or “MW”), and the average capacity of a generator (expressed in terms of average MWs, or “aMW”). The EIS correctly uses these terms and accordingly does not overstate the generating capacity of the proposed Project.

Comment: Further, the Applicant’s purpose and need statement appears to be defined only in terms of conveying power from a wind energy generation facility. This purpose and need is too narrowly limited, and avoids the question of whether there truly is a need for a wind energy project. As a result, the purpose and need statement improperly limits the alternatives considered by the agencies. [LTR 179, CMT 17]

G-45
Response: The Applicant-identified needs contained in Section 1.2.3 of the EIS are not only defined in terms of conveying power. These needs also involve developing renewable resources and diversifying the Applicant’s business. However, it is true that the Applicant has specifically proposed a wind generation project, and that is what is evaluated in the EIS. Regardless, no matter how the Applicant defines its needs, it is the agency’s need for action that defines the range of alternatives to be considered in an EIS.

Comment: The Stated Purposes Fail to Acknowledge EFSEC’s Duty to Protect State or Local Governmental or Community Interests. One of EFSEC’s mandates is to “protect state or local governmental or community interests affected by the construction or operation of the energy facility.” WAC 463-64-020. Any site certification agreement must contain conditions to meet this mandate. Id. The DEIS fails to even mention this mandate, let alone apply it. This mandate should be expressly included in the stated purpose and need for action on page 1-3 of the EIS, and should be applied and reflected throughout the DEIS. [LTR 179, CMT 19]

Response: EFSEC SEPA rules provide the option for the Applicant to prepare EIS documents, with oversight from the EFSEC responsible official. The DEIS was prepared in this manner. EFSEC and its independent consultant reviewed all DEIS information including visual resources before the DEIS was issued by EFSEC and BPA. However, neither EFSEC nor its independent consultant performed the actual visual analysis.

Comment: Originally, the agencies stated that the Applicant and its consultants would be preparing the EIS. However, because the public objected to this arrangement and pointed out that it would violate NEPA, the agencies made the following announcement in the DEIS May 21, 2010 cover letter: While EFSEC and BPA are the entities that have prepared the Draft EIS, these agencies have worked collaboratively with Whistling Ridge Energy LLC to obtain necessary information about the project and its potential impacts for the EIS. Initially, EFSEC had intended to allow Whistling Ridge Energy LLC to prepare the EIS, as allowed by SEPA; however, after public concern was raised, EFSEC and BPA decided that the lead agencies would be directly responsible for preparing the EIS. Accordingly, we have used environmental information provided by Whistling Ridge Energy LLC and its consultants in the EIS as appropriate. All such information has been independently evaluated and reviewed for accuracy by the lead agencies, as well as by an independent, third party consultant retained by EFSEC. This statement invites more questions than it answers. What was the exact nature and extent of the involvement of WRE and its consultants in the preparation the DEIS? Did they simply supply environmental “information,” as stated in the cover letter, or did they supply analysis, findings, and/or conclusions for the DEIS? [LTR 179, CMT 30]

Response: The lead agencies believe that they have produced a reasonably thorough analysis of the proposed Project that adequately considers all points of view. BPA and EFSEC staff actively and extensively participated in the preparation of the EIS, as required by SEPA and NEPA. Both SEPA and NEPA allow for the use of environmental information, in whatever form, from the Applicant for use in the preparation of an EIS. In fact, SEPA allows for an
applicant to prepare the EIS. Nonetheless, where the lead agencies used information provided by the Applicant or its consultants, this information was thoroughly reviewed and independently evaluated by the agencies to ensure its competency and accuracy. This approach is consistent with the intent of SEPA and NEPA that acceptable environment work not be redone, but that it instead simply be verified by the lead agency. Accordingly, the lead agencies appropriately took full responsibility for the scope and content of the EIS, and have fulfilled their respective responsibilities for EIS preparation under SEPA and NEPA.

Comment: There is a major difference between the applicant’s consultants supplying the agencies with information and data (such as species survey data, photographs, coordinates for turbine locations, etc.) and the applicant’s consultants drafting analysis and conclusions to be inserted into the DEIS document. Unfortunately, the DEIS cover letter does not satisfactorily explain which scenario occurred, but the extremely biased nature of the DEIS in favor of the project strongly implies an active role by the Applicant’s consultants in its preparation. [LTR 179, CMT 35]

Response: Please see response to Comment LTR 179, CMT 30 above.

Comment: Although the agencies claim to have “prepared” the content of the DEIS and independently reviewed and verified any information from the applicant, by all outward appearances this did not occur—at least with major sections of the DEIS. Rather, it appears that the Applicant’s consultants were allowed to write major portions of the DEIS. If so, then the Applicant has been allowed to exert undue influence over the content of the DEIS. The predictable outcome is a DEIS that, in effect, serves as an extremely biased and result-oriented prospectus for the proposed project exactly as proposed by the Applicant, instead of the searching and balanced decision-making document required by NEPA and SEPA. NEPA case law and guidance are clear that an applicant, such as Whistling Ridge Energy, should not be allowed to influence the analytical content of an EIS. See, e.g., Sierra Club v. Sigler, 695 F.2d 957, 962 n.3 (5th Cir. 1983) (expressing serious concern over role of private firm in preparation of EIS). An EIS must be an entirely objective analysis intended to aid the decision maker and the public in understanding the consequences of an agency decision. Thus, it is standard practice for action agencies to ensure that applicants for federal action are insulated from all aspects of EIS preparation other than providing information. Any arrangement that allows the very same consultants who drafted the application to also draft analytical content for the DEIS is improper and cannot be allowed to continue. If in fact the agencies have been relying on the Applicant’s consultants (rather than agency employees) to draft analytical content for the DEIS, then the agencies should immediately withdraw the DEIS, and should either retain new consultants unaffiliated with the applicants to prepare a revised DEIS or should ensure that a revised DEIS is drafted by disinterested agency employees. The Applicant and its consultants must not be allowed to continue to play a direct and significant role in the preparation of factual and legal conclusions in the EIS. Such a role is improper and invalidates the DEIS as the basis for further decision-making. The agencies also state that they have hired a third-party consultant who has been charged with independently verifying the content of the DEIS. However, it is ultimately the
Response: Please see response to Comment LTR 179, CMT 30 above.

Comment: An attached May 28, 2010 email string further calls into question whether EFSEC and BPA staff actually wrote the content of the EIS, or allowed the applicant’s consultants to write it. The emails show that a landscape architect with the U.S. Forest Service telephoned the EFSEC Site Manager “express[ing] concerns about the quality of the [visual resource] analysis.” The Forest Service employee asked EFSEC “who did the analysis,” “what their qualifications were,” and “whether or not a Landscape Architect was consulted during development of this section.” Apparently not knowing the answer to these questions, the EFSEC Site Manager appears to have referred the questions to the Project Manager with URS Corporation, the Applicant’s lead consultants. As with the agencies’ DEIS cover letter, this email string poses a number of questions. If EFSEC and BPA prepared the DEIS, why does it appear that EFSEC had to ask the Applicant’s consultants who wrote it? If the agencies were directly responsible for the content of the EIS, why did they not know whether a landscape architect participated in its drafting? And as the Forest Service asked, who in fact “did the analysis,” and what were their qualifications? On the face of the email and the DEIS itself, it certainly appears as if the same people who wrote the application (i.e., the Applicant’s consultants) were also allowed to prepare the analysis reviewing the application. In fact, it appears that the entire scenic resources analysis section of the application, including all analysis, findings, and conclusions, was simply lifted from the application and inserted verbatim into the DEIS. [LTR 179, CMT 36]

Response: The lead agencies believe that they have produced a reasonably thorough analysis of the proposed Project that adequately considers all points of view. BPA and EFSEC staff actively and extensively participated in the preparation of the EIS, as required by SEPA and NEPA. Both SEPA and NEPA allow for the use of environmental information, in whatever form, from the Applicant for use in the preparation of an EIS. In fact, SEPA allows for an applicant to prepare the EIS. Initial preparation of the DEIS was done by the Applicant’s consultant, including the visual resource analysis. Nonetheless, where the lead agencies used information provided by the Applicant or its consultants, this information including the visual resource analysis was thoroughly reviewed and independently evaluated by the agencies to ensure its competency and accuracy. This approach is consistent with the intent of SEPA and NEPA that acceptable environment work not be redone, but that it instead simply be verified by the lead agency. Accordingly, the lead agencies appropriately took full responsibility for the scope and content of the EIS, and have fulfilled their respective responsibilities for EIS preparation under SEPA and NEPA. A list of preparers can be found in Chapter 6 of the EIS.

Comment: The applicant here, Whistling Ridge Energy, desires to construct an additional 35 turbines on DNR lands immediately adjacent to the north of this project. This project, known as “Saddleback” or “Whistling Ridge Phase II,” has been placed on hold by the DNR, but that hold
could be removed at any time. The DEIS states that “use of these lands for project turbines was rejected from further consideration.” DEIS at 1-14. However, recent public records requests have uncovered new evidence that the use of DNR lands is still contemplated by WRE. Specifically, the attached April 9, 2010, email shows that WRE was evaluating whether a temporary FAA moratorium on certain wind projects would prohibit expansion onto the DNR lands. The DEIS fails to sufficiently address the likelihood of Phase II of this project going forward, and fails to address the cumulative impacts of expanding the scope of this project onto the adjacent land. All phases and portions of a project must be evaluated at the outset during environmental review of the first phase. See Merkel v. Port of Brownsville, 8 Wn. App. 844, 850–51, 509 P. 2d 390, 395 (1973); Indian Trail Property Owner’s Ass’n v. City of Spokane, 76 Wn. App. 430, 443, 886 P.2d 209 (Wn. App. 1994). [LTR 179, CMT 51]

Response: For the proposed action, the EIS evaluates what has been proposed to the lead agencies by the Applicant, as required by SEPA and NEPA. What has been proposed does not include development of any additional turbines on adjacent DNR land, nor does it include the interconnection of any additional power to the FCRTS. In addition, as discussed in Section 2.3.2 of the EIS, DNR is not interested in allowing development of wind turbines on the adjacent DNR land, regardless of any previously expressed wishes by the applicant. Given this situation, not only is wind development of DNR land not part of the proposed action, it is also not considered reasonably foreseeable for the purposes of the cumulative impact analysis in the EIS.

Comment: I recommend that the DEIS for Whistling Ridge be withdrawn, and that a new one be prepared. [LTR 181, CMT 63]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: While we understand that the DEIS is being prepared by EFSEC and BPA, we have concerns as to the degree of input into the document that has been received from the applicant WRE. In the recent submission from WRE they indicate that they have participated in meetings with staff and Council consultants regarding the DEIS. [LTR 184, CMT 1]

Response: Please see response to Comment LTR 179, CMT 30 above.

Comment: Based on our review, we have assigned a rating of LO (Lack of Objections) to the DEIS. This rating and a summary of our comments will be published in the Federal Register. A copy of the rating system used in conducting our review is enclosed for your reference. [LTR 189, CMT 8]

Response: Comment acknowledged.
Comment: The DRAFT states on page 1-35 – Summary of Unavoidable Adverse Impacts – Table 1-1 – Visual Resources: “The project would cause some visual impact to surrounding areas where turbines were visible, including some areas inside the Columbia River Gorge National Scenic Area. The visual impact analysis showed that the anticipated level of visual impact would not be higher than low to moderate at any of the viewpoints examined.” Greg Neely Comment 6-16-10: To state, “the visual impact would not be higher than low to moderate” is extremely subjective, given the proximity to the Columbia Gorge National Scenic Area. It’s my opinion that the most crucial viewpoints are: Hood River, Columbia River Waterway (adjacent to Hood River), Columbia River Shoreline Recreation Sites (Adjacent to Hood River and Mosier), I-84 Freeway (From Hood River to Mosier in both directions) [LTR 194, CMT 1]

Response: The criteria used for selecting viewpoints are discussed in Section 3.9.2.3 (DEIS page 3-164). Locations were chosen based upon their representation relative to the Project Area, those that were most accessible to the public, and locations with the largest number of viewers. Viewpoints from within Hood River (8, 17, and 18) and between Hood River and Mosier (11 and 12) are considered in the impacts analysis. Please refer to Figure 3.9-1, Locations of Simulation Viewpoints, to reference where the viewpoints used in this analysis are located relative to the Project Area.

Comment: Specific Comments. 1. Independent Evaluation. In our scoping comments for this project, Seattle Audubon identified multiple issues in the application that needed thorough review to adequately evaluate the potential environmental impacts of this project. Unfortunately, the DEIS fails to address many of the issues we previously identified. In many instances, the DEIS simply repeats the information presented in the application with no new analysis or documentation. We urge your agencies to ensure that the Final Environmental Impact Statement (FEIS) fully addresses these inadequacies. [LTR 196, CMT 2]

Response: Please see response to Comment LTR 119, CMT 2 above.

Comment: Distribution of Project Power: One of the applicant’s stated objectives for this project is “to provide an additional renewable resource for electrical utilities in Washington.” (DEIS p. 1-7) We welcome that intent and request that any certification for this project include a provision that the power from project be sold to Washington utility(s) as opposed to being sold into the California market. Because the potential adverse impacts of this project would be experienced locally, it makes sense to keep the project benefits local as well. In addition, such a provision would also help relieve some of the current pressure on the California intertie that is causing challenges for BPA in integrating wind resources into its transmission system. [LTR 196, CMT 12]

Response: Please see response to Comment LTR 178, CMT 39 above.
Comment: Related Concerns: 1. A first Gorge Windmill project will set a precedent. Other proposals and very likely other windmill farms will follow. New companies (for example a conglomerate such as General Electric) will be much less concerned about the welfare of this area than our neighbors at SDS. [LTR 230, CMT 2]

Response: Please see response to Comment LTR 119, CMT 11 above.

Comment: Huge steel towers with massive concrete bases would be with us a very long time. The costs of removing an obsolete windmill would be substantial. But how long would a wind tower be useful? [LTR 230, CMT 4]

Response: As discussed in Section 2.1.7 of the EIS, the proposed Project, including the wind turbines, is expected to have a useful life of at least 30 years. However, it is possible (and generally likely) that in the future, aging project components would be replaced as needed, which could extend the useful life of the Project for years or even decades beyond the current expected project lifespan.

Comment: It is the Lead Agency’s responsibility under the State Environmental Policy Act to fully consider the environmental impacts of the Proposed Action. As Lead Agencies, EFSEC and BPA need to weigh the proposal’s limited environmental impacts against its relevant and consequential environmental benefits. Of the many EISs I’ve reviewed, I cannot think of a clearer example of where the significant positive regional and global environmental consequences outweigh the negligible, local adverse impacts. [LTR 231, CMT 6]

Response: Comment acknowledged.

Comment: Related Concerns: 1. A first Gorge Windmill project will set a precedent. Other proposals and very likely other windmill farms will follow. New companies (for example a conglomerate such as General Electric) will be much less concerned about the welfare of this area than our neighbors at SDS. [LTR 241, CMT 4]

Response: Please see response to Comment LTR 119, CMT 11 above.

Comment: Huge steel towers with massive concrete bases would be with us a very long time. The costs of removing an obsolete windmill would be substantial. But how long would a wind tower be useful? [LTR 241, CMT 6]

Response: Please see response to Comment LTR 230, CMT 4 above.
Comment: The project is inappropriate in that it addresses only the fiduciary interests of a local company and not overall needs of the County, its residents or the Nation. In a time of rapidly decreasing forested areas in the world and climate change removing forest forever, i.e., 9 feet of concrete to support windmills, destroying watershed, creating lanes to move power with towers, destroying wildlife habitat, makes little sense. [LTR 245, CMT 2]

Response: Please see response to Comment LTR 179, CMT 13 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS and issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. [LTR 266, CMT 6]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS and issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 270, CMT 7]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: For the following reasons, as well as those that others have taken the time to bring to your attention, I strongly feel that a completely revised document must be created to stand as an accurate and unbiased presentation of information that Council members can use to make an informed decision regarding this proposal. [LTR 272, CMT 1]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: The existing document shows a lack of professionalism in many important areas that is inappropriate to both the SEPA NEPA requirements and the process, as well as to the scale and potential impact of the proposal upon the region and its varied resources. [LTR 272, CMT 1]

Response: EFSEC and BPA believe that they have produced an EIS that fairly and adequately analyzes the proposed Project, and that fully complies with both SEPA and NEPA. No decision has been made regarding whether or not to approve the proposed Project. That decision will come after completion of the EIS process.
Comment: [In reference to DEIS] Section 1.1.1, Pg 1, Para. 2, Interconnection, and Section 1.2.2, Pg 4, BPA Purpose and Need for Action, I do not believe that BPA has yet responded to the request for interconnection. The nearby BPA transmission lines are at carrying capacity with a backlog of other requests for interconnection. Although the location is referred to in Section 3, the precise location for the proposed Whistling Ridge Project interconnection is presently unknown, since no new transmission line has yet been constructed, nor has firm commitment from BPA to existing lines been granted. This renders the cumulative impacts assessment incomplete. It is also incomplete with respect to several other facets of this proposal as well. The BPA new line access corridor construction and interconnection costs, design and placement of any collector substation and interconnection structure, as well as an evaluation of the resulting environmental impacts of their construction and operation would be legitimate, mandatory elements for inclusion in this document. Since BPA is partially responsible for the DEIS document, it should not be problematic for the agency to include an open and clearly understandable discussion of the agency’s present interconnection problems as they relate to the current proposal, thus clarifying this aspect of the EIS. There is discussion of possibilities that were considered but rejected, however, the option finally chosen appears to be questionable, especially since BPA has offered no firm commitment. [LTR 272, CMT 2]

Response: BPA’s transmission studies for the proposed Project have shown there is sufficient available transmission capacity on existing BPA transmission system to provide transmission service for the proposed Project. In other words, no upgrades of the BPA transmission system (other than the proposed interconnection substation already considered in the EIS) would be required, and there would be no detrimental effect on this system. In addition, Columbia River hydrosystem generally has sufficient reserve capacity to provide for fluctuations in wind generation, although BPA is currently investigating potential options to ensure capacity. The potential for natural gas plants to be developed is discussed in other responses in this section. The potential for wind projects such as the proposed Project to result in cumulative impacts to Columbia River fish species due to the interplay of these operations with hydrosystem operations during certain conditions is discussed in Section 3.14.3.6 of the EIS and in other responses in this section.

Comment: [In reference to DEIS] Section 1.2.3.2, Pg 6, “...it is critical to locate projects in areas where transmission lines currently exist. The applicant thus needs to locate near existing high-voltage transmission, such as the FCRTS.” As noted above (in Section 1.2.2 notes), the currently existing BPA transmission line is running at capacity, with no possibility for the addition of large additional sources, such as this project’s proposed output would comprise. The critical issue regarding wind facilities is indeed appropriate siting, but not for the reason of proximity to transmission lines. The applicant (I assume this is the author) misunderstands the basic premise and need for an environmental impact statement. The lack of transparency regarding this issue is disturbing, and should be clarified in the BPA discussion of the issue, rendering this claim invalid. It should be removed from the document; it appears repeatedly in all Sections. [LTR 272, CMT 2]

Response: To clarify, the proposed Project would interconnect to an existing BPA transmission line that is not currently at capacity. In addition, transmission system
improvements currently being built by BPA, such as the under construction McNary-John Day 500-kV transmission line, will help further alleviate congestion on existing BPA lines in the area. The Applicant has closely coordinated with BPA staff to determine transmission capacity availability. As part of this coordination, BPA transmission planners have reviewed the proposed interconnection and found that it can be reliably interconnected, and that transmission service can be provided. The Applicant’s objective of locating near the FCRTS thus is a legitimate consideration.

Comment: [In reference to DEIS] Section 1.2.3.3, Pg 6, Business Needs of the Applicant, [a]n EIS is not a branch of any chamber of commerce nor is an EIS a forum for advertisement. The history of the applicant/company is already included in the Appendices. [LTR 272, CMT 2]

Response: Please see response to Comment LTR 76, CMT 2 above.

Comment: [In reference to DEIS] Section 1.3.2, Pg 1, “[t]he EIS will be used primarily to inform ....” As it stands, I do not feel this document yet contains the essential information needed for informed, responsible decision making, especially in the areas of wildlife impacts, soils/geology and cumulative impacts analysis. It must be improved significantly before it can serve its intended purpose. This may take more time, but it will certainly ensure that the final EIS is a more suitable document for unbiased decision-making, which at this point it is not. [LTR 272, CMT 3]

Response: Please see response to Comment LTR 60, CMT 1 above.

Comment: [In reference to DEIS] Section 1.2.3.3, Pg 6, Business Needs of the Applicant. An EIS is not a branch of any chamber of commerce nor is an EIS a forum for advertisement. The history of the applicant/company is already included in the Appendices. Other local background information is included in Section 3.10.2.1, Historic Background, and this is where it belongs. Every company has business needs but this is not the arena for such discussion. This heading and its text should be removed. [LTR 272, CMT 3]

Response: Please see response to Comment LTR 76, CMT 2 above.

Comment: [In reference to DEIS] Section 1.3.3 and 4, Pgs 8, 9, NEPA Section 102(2)(c) requires that alternatives to the proposed action be provided. There are no Action Alternatives offered in this document (the No Action Alternative is not considered a viable alternative.) Alternatives must be presented and discussed as real possibilities, not avoided by stating that alternatives were “considered but eliminated from detailed study” as is stated in Section 1.4.3. The Applicant cannot choose to avoid this requirement. Although it is stated several times that
the document “…is intended to fulfill the format and content requirements” of a joint SEPA/NEPA EIS, it falls well short in many areas. [LTR 272, CMT 4]

**Response:** The lead agencies believe that the EIS considers a reasonable range of alternatives and adequately describes these alternatives, consistent with the requirements of both SEPA and NEPA. Issues raised in these comments specific to alternatives considered but eliminated from detailed study in the EIS are addressed in other response to comments in this section.

---

**Comment:** [DEIS] Section 1.4.1.2 states that a trench, approximately 8.5 miles long and 5 feet wide would be required to place collector cables. Will the removed soil be compacted as it is returned to the trench? Will the soil returned to the trench be returned in the same order that it was removed? What will the compaction guidelines entail? Who ensures that it is done properly? [LTR 272, CMT 6]

**Response:** As discussed in Section 1.4.1.3, excavated soils will be used to backfill the trenches. Additional information on earth disturbing activities was presented in Section 3.1.2.1. Proposed clearing and grading activity will be consistent applicable codes and standard engineering practices. As mentioned in Section 3.3.1.3, test pits were conducted to assess both the near-surface soil and rock characteristics ranging in depth from 7-16 feet in depth. No groundwater was encountered at that time. It was also noted that these observations were made based on a one-time sampling event and that the actual groundwater levels may fluctuate significantly in response to seasonal effects, regional rainfall, and other factors. The Applicant will be required to prepare and implement a Stormwater Pollution Prevention Plan (SWPPP), Erosion and Sedimentation Control Plan, and Environmental Protection Control Plan to lessen soil erosion and improve water quality of stormwater run-off through stabilization practices, structural practices, and stormwater management. These plans will be developed and approved by EFSEC prior to construction or modification of any roads or facilities. Additionally, EFSEC will require the Applicant to obtain coverage under Washington Department of Ecology’s Construction Stormwater General Permit. The Stormwater General Permit (NPDES) will include BMPs to minimize erosion and runoff from the Project Area.

---

**Comment:** [DEIS] Section 1.4.1.2 states that a trench, approximately 8.5 miles long and 5 feet wide would be required to place collector cables. The DEIS mentions reseeding with of grasses and native plants, but does not mention what species, nor whether trees or shrubs that were removed would be replaced in-kind. If the plantings are to minimize noxious weed colonization would the reseeding areas be watered to ensure germination in time to counteract opportunistic germination of undesirable species? If so, the amounts used should appear in the Section 3 water use list and a watering regime presented. [LTR 272, CMT 6]

**Response:** Much of the trench area for the cables would be placed within the Project roadways as shown in Figure 2-1, Project Elements. Vegetation clearing and replanting is described in Section 3.4.2.1 of the Biological Resources Section. On DEIS page 3-72, it was noted that some areas would be permanently cleared for turbine foundations and roadways.
Except for permanently cleared areas, cleared areas would be replanted with trees within one year following construction. Areas where trees are permanently removed (such as turbine blade clearance) would be replanted with appropriate native grasses and low-growing shrubs. Implementation of a noxious weed control program, in coordination with the Skamania County Noxious Weed Control Board, is included as a mitigation measure in Section 3.4.3. It is not anticipated that reseeding would require watering.

Comment: [In reference to DEIS] Section 1.4.2, Pg 12, No Action Alternative, [t]o state that the No Action Alternative “would not help the state of Washington in achieving the renewable energy goals mandated by the state’s Renewable Portfolio Standard” is misleading. Washington State wishes to encourage renewable energy, but not to the exclusion of all else. Site selection is probably the most important way that negative environmental consequences can be avoided, especially with respect to wildlife. Moreover, BPA does not segregate power sources. Once it is produced and fed into the collection system, it is dealt with as any business commodity, in this case by bids. Much of the power we create here is used elsewhere, historically, to California. To imply that a rejection would flout state goals and policies is simplistic and a little misleading. “(The No Action Alternative) would help to meet the region’s need for additional power in the coming years.” If by “region”, “local” is meant, our regions need is not great. The Columbia River and other water-driven power-generating dams continue to supply more than 3/4 of our power needs. The current trend is to improve efficiency and to encourage both business and the private sector to conservation. It has been estimated (Draft Sixth NPP, 2009) that almost 80% of our locality’s future energy demands can be met in this way. Existing and newly approved wind facilities in the region, with a focus in Klickitat County, are more than adequate to make up the difference. It would be not only misleading but inaccurate to state or imply that there is a “need” for additional wind power in this portion of the Northwest. [LTR 272, CMT 7]

Response: The likelihood that regional power needs likely would be addressed by some combination of energy efficiency and conservation measures, existing power generation sources, and/or the development of other new renewable and non-renewable generation sources under the No Action alternative was acknowledged in Section 2.2 of the EIS. The discussion of the likely implications of how the No Action alternative would relate to RPS and regional power needs identified by the Applicant is meant to provide a general description of this alternative’s responsiveness to these needs. Simply put, not developing the Project would indeed not help achieve RPS goals, and also would not provide a source of additional power. To clarify information concerning the RPS, the discussion of this RPS in the No Action alternative has been revised to reflect that achievement of other states’ RPS goals also would not be helped under this alternative.

Comment: [In reference to DEIS] Section 1.4.3, Pg 13, Alternatives Considered but Eliminated from Detailed Study, [t]he applicant’s response is in violation of the guidelines by virtue of not complying with the requirement to supply Alternatives. As mentioned above, an EIS requires that alternatives be provided and considered, with accompanying data and analysis to match all of the other Action Alternatives presented. [LTR 272, CMT 7]
Response: The lead agencies believe that the EIS considers a reasonable range of alternatives and adequately describes these alternatives, consistent with the requirements of both SEPA and NEPA. Issues raised in these comments specific to alternatives considered but eliminated from detailed study in the EIS are addressed in other response to comments in this section.

Comment: [In reference to DEIS] Section 1.4.3.1, Pg 13, Alternative Project Locations, [t]he contents of this portion are redundant. Again, it avoids the EIS requirement regarding Alternatives. The points made here have all been stated previously {Section 1, 4.1}, in the same bulleted form and with almost the same wording. [LTR 272, CMT 7]

Response: Please see response to Comment LTR 22, CMT 2 above.

Comment: [In Table 1-1 on DEIS page 1-22 under “Earth: Construction, Design and Mitigation Measures”] All of the Design and Mitigation Measures listed are “would be” statements. They “should be” already part of the EIS! If, for instance there was a critical subsurface condition, it needs to be known and factored into the decision process, not “discovered” after approval. Only in this way can accurate and responsible evaluation occur. Because of the difficult terrain, there would appear to be very little possibility for adjustment, should geologic constraints be revealed initially. This could easily endanger the viability of the project, which underscores the importance of having data collected from rigorous studies, and analysis conducted by respected sources. Even with the added benefit of such information, the impacts of such radical alterations to a fragile topography can only be guessed. Stringent geologic study of the proposed site must be performed now and the results reported in another, hopefully improved Draft document. This information will be essential for the Council’s evaluation. Without it, the process will have no merit. [LTR 272, CMT 8]

Response: Comment acknowledged.

Comment: As mentioned above [in LTR 272, CMT 6], there is no doubt that the proposed excavated and refilled trench will impact and redirect existing subsoil water flows for 8.5 or more miles and may potentially influence an area far greater than the area of the trench. It is also possible that drainage may be improved in the trench after refill, but the possibility that it will not, must be at least considered. [LTR 272, CMT 9]

Response: Comment acknowledged.

Comment: In [Table 1-1 on DEIS page 1-22 under “Earth: Construction and Operation”], the considerable alterations to the terrain that are proposed for this project - 8.5 miles of three to four foot deep, five foot wide trenches for cable burial, 30-foot deep turbine pads that will
require leveling with machinery and extensive blasting to excavate, the building of adequate access and delivery roadways on steep slopes - will certainly have more impacts, and ones that influence each other more closely, than those listed. The changes made to accommodate the towers will forever alter the ridge tops and they will not revert to their pre-construction profiles after the project is decommissioned. It is inaccurate as well as disingenuous to state that the project construction requirements would be “minor to moderate.” [LTR 272, CMT 9]

Response: Section 3.1.2.1 describes the types of earth disturbing activities that would occur on the site, including tree harvesting in areas not already cleared; constructing roads and turbine crane pads; constructing foundations for turbine and meteorological towers; trenching for underground utilities; clearing and grading for the substation placement; and clearing and excavating for the foundation for the Operations and Maintenance facility. While these activities would affect approximately 108 acres (56 acres of permanent disturbance and 52 acres of temporary disturbance) the resulting change in the ground surface elevation would be minimal in comparison to the varied topography on the site. In addition, most areas affected by ground disturbing activities would not be visible from lower elevation areas surrounding the site.

Comment: [In reference to Table 1-1 on DEIS page 1-22 under “Water: Construction and Operation], On-site development will certainly impact ground and surface water drainage patterns as indicated above. It is well-recognized that new roadbeds alter water flow significantly and are responsible for a good deal of continuing erosive runoff. The replacement of natural soil and rock drainage on the site with impervious concrete pads constitute large surface areas that will prohibit slow drainage. Water will be quickly released from these surfaces in large quantities at approximately the same time, limiting the remaining soil's ability to absorb and release it slowly. Some of the remaining soil may be additionally compacted from heavy construction machinery, limiting even more its ability to absorb rainfall and melting snow slowly. Section 3 down plays the impact these impervious surfaces may have upon soils, but this need to be seriously examined. Each of the 49 tower pads have a diameter of 60 feet, creating 2920 square feet of impervious surfaces at the top of steep ridges. These conditions produce fast runoff accompanied by high erosion which, over time may lead to catastrophic geologic events, as well as degrade waterways used by fish, amphibians and invertebrates. Amend this inaccurate denial of the project's impacts to ground and surface waters. A discussion, or at the very least a mention of the runoff potential should be presented, as well as possible impacts to the larger streambeds below, with potential to impact fish, amphibians and invertebrates, upon which fish depend for food. Larger game and non-game animals may be impacted as well through water quality degradation and the possible inability to even reach water. The standard BMP guidelines will not be adequate for this anticipated situation. In recognition of this, an individual plan to accommodate the special runoff problems of the project could be developed as part of a mitigation plan, implemented and monitored by an agent other than the applicant/contractors, if the project is approved. The cumulative impacts discussion should deal with this possibility as well, but does not. [LTR 272, CMT 10]

Response: As discussed in Section 3.1.3 and in other responses, EFSEC will require the Applicant to obtain coverage under Washington Department of Ecology’s Construction
Stormwater General Permit. The Stormwater General Permit (NPDES) will include BMPs to minimize erosion and runoff from the Project Area.

Comment:  [In reference to DEIS] Section 1, Table 1 Pg [1-]24 Biological Resources: Construction Soil compaction is an undesirable and irreversible impact that should be acknowledged since it affects soil drainage, the ability of certain plants to grow well and limits the species of plants that will grow. In addition to “loss of suitable habitat,” abandonment of adjacent suitable habitat due to construction activity should be considered a likely possibility. Some bird, mammal and invertebrate species are known to be more sensitive to intrusive activities, including noise, than others. Several of these species are listed as being present in the project area. Add “abandonment of suitable habitat due to construction activity” to the list on page [1-]24. [LTR 272, CMT 11]

Response: The potential loss of suitable habitat and disturbance and displacement from construction activities was listed on Page 1-24 of the DEIS in the “Impact” column for “Biological Resources.”

Comment:  [In reference to DEIS] Section 1, Table 1 Pg [1-]24 Biological Resources: Operation “There would be some mortality to birds and bats due to turbine collision and displacement, though not in sufficient numbers to affect population viability.” I restrain myself when I say that this statement is offensively inaccurate. It also reveals the applicant’s misunderstanding of the “cumulative impact” concept. As wind farms proliferate in our region, the cumulative mortalities become increasingly significant for individual populations, regardless of their population status. Just because there have been no studies addressing bird population declines in association with wind installations does not mean that one has a legitimate claim to deny that such a relationship may exist. The bat studies cited, employed equipment that was not capable of determining the bat species e present. How then, can an assessment of a particular population be made? Or, by extension, a statement regarding population viability? What authority provided the status information for each population? What is the source of data for western bat species population size? Eastern bat species are being threatened with mass extinctions from White Nose Syndrome, the etiology and causative organism of which is still unknown. The disease has not yet reached the western states; because of this, it is essential that ALL western bat populations be given added protection, regardless of their population status. The bat study data is inadequate in certain respects; the study plan assumptions were not adequately rigorous, there were discrepancies in data collection procedures from year to year, making comparisons and data merging ineffective; long-term sampling frequency was sparse. At the very least, a repeat survey should be conducted which would identify bat species. The Columbia River Flyway is a major East to West migration route that has likely been used longer than mankind has been here. Raptors are known to use mountain ridges for North/South travel as well as for hunting in this part of the Columbia River. People come from many places outside of this area specifically to see the variety of birds that congregate and fly through this river corridor, some stopping to feed for a few days or weeks before moving on. This site would be an unconscionable choice for a development of this kind, with this knowledge. “No impacts to
listed species” - is this a wish, or a promise from an unknown deity? How can it possibly be known ahead of time that a listed species will not be impacted; especially when inadequate studies have failed to identify what species use the area and with what frequency? And when only a two year start-up mortality study is planned? This is not enough time to obtain meaningful data much less to make any conclusions from the data. The project location would be an especially difficult one for such monitoring due to the terrain and planned forestry understory management activities. A recent eastern U. S. mortality study is employing dogs to find bat carcasses, because they are so difficult to locate by eye, even in dry flat grassland. There is no body of information available documenting how wild animals might respond to the sound of wind turbine propellers. This should be at least briefly discussed and dealt with as a possible impact. [LTR 272, CMT 12]

Response: The Wildlife Society, in a landmark publication on wind energy and wildlife, concluded that fatalities of passerines from wind turbine strikes generally are not significant at the population level (Arnett et al. 2007). Also, the National Academy of Sciences (NAS 2008) recently reviewed wind energy impacts on birds, and came to the following conclusion: “At the current level of wind-energy development (approximately 11,600 MW of installed capacity in the United States at the end of 2006, including the older California turbines), the committee sees no evidence that fatalities caused by wind turbines result in measurable demographic changes to bird populations in the United States, with the possible exception of raptor fatalities in the Altamont Pass area.” The available information suggests that the Project would be unlikely to have population impacts on birds. Additionally, the revised report “Analysis of Cumulative Impacts on Avian, Bat and Habitat Associated with Wind Energy Development in the Columbia Plateau Ecoregion of Eastern Washington and Oregon” (WEST 2010) prepared for Klickitat County does not suggest the possibility of cumulative population impacts on birds. Operational adjustments such as increasing turbine cut-in speeds during low wind speed nights can be used to mitigate bat mortality if it is found to be warranted.

Comment: [In reference to DEIS] Section 1, Table 1 Pg [1-]24 Biological Resources: Design and Mitigation Measures. “In order to avoid or minimize impacts to any raptors potentially nesting on or near the project site, a raptor nest survey would be conducted ...” Then what? A survey is not a mitigation measure. The composition of the proposed Technical Advisory Committee members is not well thought out. Entities or personages that have vested interests or have demonstrated no interest, cannot be relied upon to make responsible, nor to make informed mitigation recommendations. To include the developer on such a committee would be unwise as well as unfair to the resources. If this route is pursued, enforcement capabilities must be granted and there must be a preponderance of resource advocates as committee members. TAC groups are by reputation, generally ineffective when they have no powers. They are also rendered ineffective if members have conflicts in interest, as counties and developers often do. This would be a great opportunity to cast aside TACs, breaking out of the customary mold and devising a new and more effective way to resolve monitoring and mitigation issues associated with such a project. “For potential impacts to big game species (deer and elk) coordination with WDFW will occur if appropriate.” Again, just to mention something does not comprise a mitigation measure. What about bears, and large cats? Who decides if a situation is “appropriate” warranting consultation? Under what circumstances would it be appropriate to coordinate?
The project location is a designated wintering area for elk. What plant species are present that elk might use for winter forage? Will these species be replanted and therefore present in adequate quantities to continue to serve as winter forage during construction and operation of the proposed project? These considerations must be treated responsibly. Somewhere in the document, the quoted statement is vague and obtuse. It leaves the reader with no information about how big game species’ use of the area will be approached, nor does it correct nor solve any problems big game species may have because of the project. [LTR 272, CMT 13]

Response: Composition of the TAC will be based on the WDFW wind power guidelines. The TAC will develop appropriate mitigation measures as warranted.

Comment: [In reference to DEIS] Section 1, Table 1[-1], “Energy and Natural Resource: Operation,” [t]he “Minor quantities of lubricating oils .....” should be specifically quantified, if only as an estimate, to be consistent with the remaining listed items. [LTR 272, CMT 14]

Response: Table 1-1 has been modified to include “less than 5 50-gallon drums” after this bulleted item to correspond with what is also listed in Section 3.6.2.1.

Comment: [In reference to] Section 1, Table 1[-1], Pg 25, Environmental health: Construction, [t]he project is located at the southern end of a wide contiguous band of lands termed “Fire-prone Landscape Management Strategy Area” by a USFWS, 2008 Final Spotted Owl Recovery Plan map. This area runs from the Columbia River north to the Washington-Canada border. The increased risk of fire during the summer months must be seriously considered and aggressive prevention measures above the usual standards should be pursued and stipulated. Prohibitions on conducting potential spark and fire-generating activities during the driest fire danger periods of the year could be part of a plan keyed to this project and would demonstrate care and concern for nearby communities. A several month delay in certain construction activities and equipment use as a result of time-of-year prohibitions would be well justified and need not halt all building progress. There WILL be blasting activity in association with this project, if approved. Getting rid of the “may” and “could” in the bullet dealing with blasting would be a more honest way of stating the realities of the massive environmental reshaping that this project will engender. If “[b]lasting could also create a fire hazard during dry weather”, then this activity should be curtailed during these periods. Likewise, an activities plan related to the regional weather patterns might suggest avoiding blasting during unusually wet times of the year to avoid problems similar to those encountered recently along Hwy 14. There is no doubt that the level of blasting activity alone has the potential to seriously destabilize this particular environment, which, as noted elsewhere, already has nearby unstable loci. Since there is no geologic assessment data provided, it is impossible to even guess what impacts such activity could produce. When the geologic assessment is conducted, it should address not only immediate impacts but the potential long term impacts of blasting, even although this would only be predictive. Road department records from Underwood and Hwy 14 should give the Council a good idea of the areas’ historic instability. [LTR 272, CMT 15]
Comments: In Section 1-6, Table 1-1, under “Environmental health: Construction” (Column 4), the second, bulleted statement in column 4 implies that a fossil-fuel-powered facility might supply fill-in power when a wind facility is unproductive (and that it would carry a higher risk of fire.) There is a federal requirement mandating that alternative power source facilities must accompany any new wind facility, based upon the amount of power generated. The proposed wind project would generate above the MW threshold, requiring the construction of an alternative power-generating facility to balance a wind farm’s unproductive periods of no wind or too high wind. The construction cost of this requirement building, inter-tie costs, should certainly be included in the cost analysis for this project, but it does not appear. Since the alternative power facility is a requirement, its location should be identified and the associated environmental impacts need to be included in the EIS, including the cumulative impacts portion. [LTR 272, CMT 16]

Response: BPA has several procedures in place to operate with wind facilities interconnected to BPA’s transmission grid. BPA allocates some balancing capacity to wind facilities under the BPA Balancing Authority. Wind Facility Developers pay for this capacity through BPA transmission rates. In addition to BPA transmission rates, generators are subject to Generation Imbalance which is also used to balance the wind output. BPA currently manages imbalances using the Federal Columbia River Power System (through the use of federally-managed dams on the Columbia River). For the long term, BPA is also evaluating other possible alternatives including self supply. More information regarding BPA’s Customer Supplied Generation Imbalance, please visit http://transmission.bpa.gov/wind/gen_imbalance/. For more information regarding BPA’s Wind Integration Team, please visit http://www.bpa.gov/corporate/WindPower/WIT.cfm. Lastly, for more information regarding BPA’s Wind Power initiatives, please visit http://www.bpa.gov/corporate/windpower/index.cfm. Furthermore, a discussion of energy balancing can be found in Section 3.14.3.5.

Comment: In reference to] Section 1, Table 1[-1], “Environmental Health: Operation,” again, with respect to fire potential, local ordinances and other regulations and standards are not directed to such a project, and are not adequate, because of the unusual situation. An individually tailored, aggressive fire prevention plan and response tactic needs to be developed for the construction and operation phases of this proposed project. Relying on existing regulations will not adequately address the specific potential hazards nor protect the nearby population and environment. “...none of the planned turbines are within 2,500 feet of existing residences.” This is not correct; there is one residence. Mitigation measures should be included in the proper column. “EMF from the project ... would have no health and safety impacts.” I do not see any information in the document to support this assertion. There is certainly study regarding the issue, but conclusions are not definitive at this time. Can a pronouncement be
made if there is inadequate documentation? Unless this can be produced, this statement needs to be removed or qualified in some manner in order to be objective. [LTR 272, CMT 17]

Response: Fire mitigation measures are included in the proper column within Table 1-1; and Fire Protection and Prevention Plans are addressed several times in Section 3.6. Additionally, both “Fire and Explosion” and “Electromagnetic Fields” analysis during construction and operation of the proposed Project can be found in Section 3.6.2, Impacts, and the mitigation measures associated with both of these issues can be found in Section 3.6.3, Mitigation Measures, of the EIS.

Comment: [In reference to] Section 1[.6], Table 1[-1], “Noise: Construction,” [t]his section down plays construction noise, which will carry well into the valleys and bounce off of adjacent hillsides. Although construction is stated to occur during daylight hours, it will likely begin very early and continue through dusk. The added noise of myriad transportation trucks will certainly impact local residents on a daily basis and should be included in the list. The noise from blasting will certainly be noticeable and will last for awhile. In thoroughness, it should also be mentioned. Section 1, Table 1 Pg 27 Noise: Operation An in-depth submission regarding wind turbine noise impacts upon humans has been submitted. Please consider it as a counter to the data presented in the EIS and take appropriate action to modify the table. [LTR 272, CMT 18]

Response: As described in Section 3.7.2.2, construction related noise between 7:00 a.m. and 10:00 p.m. is exempt from noise regulations per 173-60-050 WAC.

Comment: [In Section 1-6, Table 1-1, under] “Socioeconomics: Operation,” [t]here are several studies that identify undesirable affects of turbines upon humans {see K. Brown’s testimony citations}. One would not unreasonably conclude that properties in close proximity to such turbine arrays might be less desirable for habitation, at least to a percentage of the population. Proponents of wind power have issued statements derived from studies indicating that property values are not adversely affected by nearby wind turbines. As such studies continue, depending on the analyses, certainly there is the possibility that property values may be affected one way or another, but for now either position can support and document its claims. [LTR 272, CMT 19]

Response: Comment acknowledged.

Comment: [In Table 1-2 on DEIS page 1-34, “Summary of Unavoidable Adverse Impacts: Earth”], the enormously disruptive activity that will be required to complete this project, located in a geologically fragile environment that has already been subjected to considerable alteration, is very likely to respond with undesirable events. In potentially susceptible areas, no amount of “careful design” can prevent, nor can “mitigation measures” restore, areas where mass wasting has occurred. It should be added to the list of potential adverse impacts, especially since
evidence of such an event was documented during a previous survey. The severe re-contouring, blasting, large-scale trenching and creation of impervious surfaces all increase the likelihood of minor or major responses from the environment. The soil types in some areas are acknowledged to be susceptible to erosion and the proposed “A” array is located precisely along a Class II \{High Landslide Hazard Area\} ridgeline. To dismiss these and other known geologic concerns with the two brief dismissive statements presented is unacceptable. Until a reputable geologic assessment study is performed, there will remain a glaring gap in this arena. Without professional scientific data, any predictive statements can only be considered arbitrary and of dubious merit. \[LTR 272, CMT 20\]

Response: As discussed in Section 2.1.2, final siting of the wind turbines and associated facilities would be done following completion of the EFSEC Site Certificate. Prior to this final siting process, as a condition of the Site Certificate and as discussed in Section 3.1.3, a detailed geotechnical investigation of the specific locations of all wind project elements would be conducted. If this investigation indicates the potential for slope instability at turbine sites or other Project facilities such as access roads (including improvements to West Pit Road), these facilities will be redesigned or relocated to avoid this risk. As discussed in Section 2.1.3.7, all road improvements required for the proposed Project would be designed and constructed under the direction of a licensed engineer, in accordance with the Skamania County Private Road Guidelines and Development Assistance Manual. All county roads requiring improvements would be designed and constructed in accordance with the WSDOT Design Manual.

Comment: [In reference to Table 1-1 on DEIS page 1-22 of the under “Air Quality], [c]onstruction activity would involve many more pieces of diesel-fueled machinery than any logging operation. It is absurd to think that the residents of the town of Underwood will not notice, nor be affected by, a continuing stream of diesel trucks heading up and down the roads every day for months. Peak morning hour numbers of trucks are estimated to be 210/hr for 3-5 months. Further, all major construction equipment is to be diesel-powered (Section3 Table 6-5, Pg 109 Fire and Explosion Risk Mitigation.) It is disingenuous to claim that this would be comparable to “existing logging operations”, and equally so to state that “the project would contribute to a beneficial impact on overall air quality.” Climatological data presented in the EIS indicates that the area is prone to air stagnation at all times of the year, but especially during the summer when pollutants from downriver may collect forming considerable haze. Even if this statement refers to the completed project, it is a bit of a stretch to claim “beneficial impacts on overall air quality” when the requirement to build alternative fuel power plants are a direct result of building wind powered facilities. With this in mind, it might be fairer to consider that project would lead to a decline in overall air quality. [LTR 272, CMT 21]

Response: The temporary effects on air quality from construction activities are described in Section 3.2.2.1. Mitigation measures to address those effects are described in Section 3.2.3.

Comment: [In reference to DEIS] Section 1, 7 Pg [1-]34 Summary of Unavoidable Adverse Impacts: Biological Resources. See previous comments regarding bats and birds (Section 1,
Table 1 Biological Resources: Operation. The Summary statement simply reiterates the document text statements, almost word for word, imparting the same inappropriate lack [...] [LTR 272, CMT 22]

Response: The summary table is intended to summarize information found elsewhere in the EIS. It does not provide new or additional information.

Comment: Precedent. We feel that if Whistling Ridge is allowed to move forward, the Governor of WA would be setting a dangerous precedent here in the Columbia River Gorge. What will stop other wind farms from being allowed just outside the geographical boundaries but visually impacting the NSA? We have already sacrificed the natural beauty of the Columbia Hills east of the NSA to hundreds and perhaps even thousands of wind turbines on both sides of the Columbia in the interest of this green energy that must be subsidized to make ANY economic sense. How far should we go with this philosophy of creating green energy? At what cost? As common sense tells us, if it sounds too good to be true, it probably is, as evidenced by the ethanol political boondoggle. [LTR 273, CMT 1]

Response: Please see response to Comment LTR 119, CMT 11 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS and issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 275, CMT 5]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: In reading this DEIS, one thing stands out. Rather than being a decision making document, which DEISs are supposed to be, this appears to be a justification document, providing support for a decision that is already in the mind of the preparers. The failure to analyze more than two alternatives - the applicants desired outcome and the required do-nothing alternative - strengthens that impression. [LTR 276, CMT 1]

Response: EFSEC and BPA believe that they have produced an EIS that fairly and adequately analyzes the proposed Project, and that fully complies with both SEPA and NEPA. No decision has been made regarding whether or not to approve the proposed Project. That decision will come after completion of the EIS process.
Comment: There should be a rationale, by the proponents, as to why they are proposing for this wind farm, and all the others in WA and OR and other areas. [LTR 279, CMT 11]

Response: The reasons behind the Applicant’s proposal for a wind generation project at the proposed site are provided in Section 1.2.3 of the EIS. The Applicant is not currently proposing any other wind projects in Oregon, Washington, or other states.

Comment: They should also explain why this proposed wind farm is needed, or if it really is needed, in the energy grid. [LTR 279, CMT 20]

Response: Please see response to Comment LTR 279, CMT 11 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 287, CMT 6]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Indeed, the EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 288, CMT 6]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 289, CMT 7]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, near the Skamania and Klickitat county lines. It is vital
that we develop alternate and renewable-energy sources, but it is just as vital that we do not repeat the same kinds of mistakes we have committed with dirty energy; namely, destroying the natural world, its ecosystems, and beauty in order to develop more energy. This project has not been well analyzed in the DEIS. Another more critical look is required. [LTR 290, CMT 1]

Response: Please see response to Comment LTR 60, CMT 1 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 290, CMT 7]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 291, CMT 8]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 292, CMT 7]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 293, CMT 6]

Response: Please see response to Comment LTR 66, CMT 4 above.
Comment: Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 294, CMT 7]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. [LTR 307, CMT 8]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. [LTR 308, CMT 8]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected. [LTR 309, CMT 8]

Response: Please see response to Comment LTR 66, CMT 4 above.

Comment: The DEIS is fatally flawed and incomplete because of their lack of technical input about the cumulative impacts and effects of this project on our environment and ecosystems. [LTR 311, CMT 16]

Response: Please see response to Comment LTR 60, CMT 1 above.
Comment: BPA needs to be an active participant in this process and so far they have totally abrogated their regulatory obligations under NEPA. The Whistling Ridge wind farm DEIS is incomplete and should be redone with BPA’s input. [LTR 311, CMT 16]

Response: The lead agencies believe that they have produced a reasonably thorough analysis of the proposed Project that adequately considers all points of view. BPA and EFSEC staff actively and extensively participated in the preparation of the EIS, as required by SEPA and NEPA. Both SEPA and NEPA allow for the use of environmental information, in whatever form, from the Applicant for use in the preparation of an EIS. In fact, SEPA allows for an applicant to prepare the EIS. Nonetheless, where the lead agencies used information provided by the Applicant or its consultants, this information was thoroughly reviewed and independently evaluated by the agencies to ensure its competency and accuracy. This approach is consistent with the intent of SEPA and NEPA that acceptable environment work not be redone, but that it instead simply be verified by the lead agency. Accordingly, the lead agencies appropriately took full responsibility for the scope and content of the EIS, and have fulfilled their respective responsibilities for EIS preparation under SEPA and NEPA.

Comment: I support this project. The EIS for Whistling Ridge has properly analyzed the environmental impacts; therefore, the project should be approved. [LTR 317, CMT 1]

Response: Comment acknowledged.

Comment: I support this project. The Draft EIS is comprehensive and complete and no further analysis is needed. [LTR 317, CMT 7]

Response: Comment acknowledged.

Comment: The DEIS needs to be revised to reflect that if the project isn’t built our growing electricity needs will be met through conservation, efficiency, and new clean energy development. Whistling Ridge is not critical to meet the forecasted need for renewable energy resources. [LTR 318, CMT 27]

Response: The likelihood that regional power needs likely would be addressed by some combination of energy efficiency and conservation measures, existing power generation sources, and/or the development of other new renewable and non-renewable generation sources under the No Action alternative was acknowledged in Section 2.2 of the EIS.

Comment: The 14th amendment is the due process clause...requires that interested parties be given reasonable notice and a reasonable opportunity to be heard. It is completely
unreasonable to expect the layman or even a trained professional to read a document of this magnitude and make informed comments in three weeks or even three months... I would like to formally object to these proceedings as we are denied reasonable notice and opportunity to be heard and are therefore being denied our constitutional rights. I would like an order extending the time for written comments for a minimum of 90 to 120 days from the currently deadline.

[LTR 317, CMT 31]

Response: Please see response to Comment LTR 66, CMT 5 above.

Comment: The DEIS is so deficient...A year ago we all presented comments, I didn’t see anything about the comments I presented in the DEIS. [LTR 317, CMT 32]

Response: Please see response to Comment LTR 119, CMT 2 above.

Comment: I commend the commissioning of an excellent document. It provides a rock solid foundation to perform your action. [LTR 317, CMT 42]

Response: Comment acknowledged.

Comment: We have not received adequate time to review the document. We need another chance to speak after we have had time to read the document. [LTR 317, CMT 44]

Response: Please see response to Comment LTR 66, CMT 5 above.

Comment: Why are other fed agencies not cooperating agencies? [LTR 317, CMT 84]

Response: Please see response to Comment LTR 74, CMT 4 above.

Comment: I feel the DEIS is very incomplete and poorly done. [LTR 317, CMT 86]

Response: Comment acknowledged. Please see response to Comment LTR 60, CMT 1 above.

Comment: The Yakama Nation would like a continuance of 30 days to review and comment on the project. The staff has not had a chance to meet on this important matter and would like to
provide input. Harry Smiskin and Lavina Washine want a written response from you on this 30-
day consultation process. [LTR 318, CMT 19]

Response: An extension was offered to The Confederated Tribes and Bands of the Yakama
Nation in which comments from the Yakama Nation were expected by August 20, 2010.
Additionally, please see response to Comment LTR 66, CMT 5 above.

Comment: The Park Service concluded that under NEPA they are required to consult. You
solicited the Forest Services’ comments, you need to take them into consideration. [LTR 318,
CMT 28]

Response: The commenter is incorrect that the National Park Service has stated that the lead
agencies must conduct some sort of consultation with the Park Service. The Park Service did
submit a comment letter on the DEIS, which is addressed in the responses to comments.
Similarly, comments received by the U.S. Forest Service have been addressed.

Comment: Page 1-7 states that “No other Federal agencies have been identified as
cooperating agencies for the EIS at this time.” Is that because National Parks Service and the
Forest Service have made concern negative comments about this proposal as it is now written?
[LTR 318, CMT 34]

Response: Please see response to Comment LTR 74, CMT 4 above.

Comment: Why have the Yakama Nation not been involved in the DEIS when they as a
sovereign nation have legitimate cultural resource concerns? [LTR 318, CMT 35]

Response: As described in Section 1 and Section 3.10 of the EIS, the lead agencies, along
with the Applicant, are in the process of coordinating with members of the Confederated Tribes
and Bands of the Yakama Nation concerning the proposed Project, and the Yakama Nation has
been afforded numerous opportunities to be involved in the process. Both the Yakama Nation
Cultural Resources Department and two local resident tribal members have been contacted to
assist with the identification of potential sensitive, traditional, and/or sacred resources. In
addition, consultation is occurring through the Section 106 process.

Comment: I do not feel this document is satisfactory in providing an objective document for
public access to information and divide decision makers to their tasks as well. [LTR 318, CMT
38]
**Response:** EFSEC and BPA believe that they have produced an EIS that fairly and adequately analyzes the proposed Project, and that fully complies with both SEPA and NEPA. No decision has been made regarding whether or not to approve the proposed Project. That decision will come after completion of the EIS process.

---

**Comment:** I do not feel that the discussion of business needs in Section 1.2.33 is appropriate. The only information relevant was the portion that mentioned the amount of construction jobs. [LTR 318, CMT 39]

**Response:** Please see response to Comment LTR 76, CMT 2 above.

---

**Comment:** Please give us additional time to review the document. Three weeks is not enough. [LTR 318, CMT 49]

**Response:** Please see response to Comment LTR 66, CMT 5 above.

---

**G.2 PROPOSED ACTION AND ALTERNATIVES**

**Comment:** The Draft EIS is correct in its assessment of the Whistling Ridge Energy Project as an “‘integrated whole,’ as a single power plant, not pieces of a whole, where some turbines may be eliminated.” The project, at 75 megawatts, is the smallest project proposed or operating in Washington State. No exception. The economic viability of the project hinges on SDS being able to complete the project as designed - at 75 megawatts. Those who suggest that they can support the project if “only” seven turbines are removed are, in effect, telling you that the project should not proceed. It reminds me of the used car dealer who claims that he’s offering you a great deal while acknowledging that the auto lacks a small item: a transmission. In the interest of fair evaluation, the proposed project before you must be considered as an “integrated whole.” Given the economies of scale and utility demand for renewable power, this project, if it is to proceed at all, cannot be downsized. [LTR 61, CMT 1]

**Response:** As discussed in Section 2.3.2 of the EIS, the Applicant considers a 70-MW project as the minimum size required to make the proposed Project economically feasible. In addition, the Applicant believes this is the minimum size needed for utilities looking to fulfill RPS requirements, based on the Applicant’s assessment of other wind projects that have successfully entered purchase agreements with utilities seeking to meet RPS requirements. The lead agencies believe these are reasonable requirements for the proposed Project.
Comment: I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood area, along the Skamania and Klickitat county lines. I am concerned that the DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), and other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. [LTR 66, CMT 1]

Response: The lead agencies believe that the EIS considers a reasonable range of alternatives and adequately describes these alternatives, consistent with the requirements of both SEPA and NEPA. Issues raised in these comments specific to alternatives considered but eliminated from detailed study in the EIS are addressed in other response to comments in this section.

Comment: This DEIS is insufficient in that an appropriate EIS has a list of alternatives. This one only lists one action item and mentions throughout the document that it is one of the alternatives. How can the proposed action also be an alternative? The only alternative stated is the No Action Alternative. [LTR 74, CMT 2]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: I have never seen an EIS, especially for a project of this scope that has no other action alternatives. Although they are mentioned in the text, they must be dealt with as real possibilities, regardless of the fact that the proponent does not wish to spend the additional funds it is claimed they would require. [LTR 76, CMT 11]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: The Whistling Ridge draft EIS is basically well organized and readable. Nevertheless, it is insufficiently thorough and contains specific inaccuracies and subjective conclusions. Some shortcomings we noted are: 1.) An appropriate EIS should list a range of alternatives. However, the draft lists only one action alternative. More alternatives could be developed by such means as relocating or eliminating problematical turbine sites. [LTR 79, CMT 1]

Response: The concerns over turbine corridor A1-A7 are noted. As discussed in the EIS, however, the Project has been proposed as an “integrated whole”, meaning essentially as a single power plant, not as a dissectible project where some turbines may be eliminated. An alternative that would eliminate turbine corridor A1-A7 therefore was considered and eliminated from further study. Nonetheless, in determining whether to issue a site certificate and enter a site
certificate agreement for a proposed generation project, it is within authority of the State of Washington to condition approval of the proposed Project, consistent with RCW 80.50 and other applicable state statutes. In the draft certification agreement, EFSEC is empowered to include “conditions to protect state or local governmental or community interests affected by the construction or operation of the energy facility.” See RCW 80.50.100. These conditions essentially serve to mitigate potential environmental or social impacts of the proposed Project. Accordingly, certain conditions, such as limiting the location of proposed turbine corridors, could be considered as a condition for project approval (i.e., as a form of mitigation related to the Project’s potential impacts).

Comment: Applicant SDS owns 70,000 acres of land; within this expanse, the draft claims that Whistling Ridge is best suited for a wind farm. But considering such large ownership, plus numerous valid concerns associated with Whistling Ridge, the draft should address in detail other potential wind power locations on SDS lands. [LTR 79, CMT 2]

Response: The lead agencies believe that the DEIS presented a reasonably thorough discussion of the consideration of alternatives for the proposed action, including why alternative locations were not being further studied. The reasons that the Applicant proposed its wind project at this particular location is explained in Sections 1.4.1 and 2.3 of the EIS. As discussed in these sections, a variety of factors were considered in evaluating whether alternative locations might be feasible.

Comment: We therefore request that EFSEC and BPA carefully study and analyze all possible adverse effects of the Project in its proposed location and evaluate whether other locations would be more appropriate for this type of project. [LTR 119, CMT 3]

Response: Please see response to Comment LTR 79, CMT 2 above.

Comment: Location of the Project. It would appear that there are much better places to site a project of this magnitude. There are thousands of acres of farmland in Eastern Washington that can (and do) support this type of development. The land to the East is vast, it’s close to transmission lines, it is many miles away from homes, has limited recreational value, limited wildlife (as compared to a forest), limited renewable resource (as compared to the timber resources here), there is limited damage to the ecosystem due to installation and it would not detract from views of a National Scenic area. We request that the EIS fully evaluate all of these considerations. [LTR 119, CMT 10]

Response: Please see response to Comment LTR 79, CMT 2 above.
Comment: Thank you for the opportunity to comment on the DEIS for Whistling Ridge. After reading though this document, I realized that there is a workable solution that could satisfy common ground that could satisfy many of the residents of Skamania County, and people Columbia Gorge National Scenic Area. The workable solution I recommend is to approve of the Whistling project with the exception of the A1-A7 turbine group. [LTR 124, CMT 1]

Response: Please see response to Comment LTR 79, CMT 1 above.

Comment: Eliminating the A1-A7 turbines would make this project much more acceptable to the local population because the impact to the National Scenic area would be much less. I request that you review these comments each as if you lived here, please remember, this project is in everyone’s back yard, it is a National Scenic Area and one of the most traveled tourist destinations in the Northwest. [LTR 124, CMT 10]

Response: Please see response to Comment LTR 79, CMT 1 above.

Comment: Regarding “future developments”, the “Middle Mountain Wind Project” should be updated to indicate that the Hood River County Commissioners have determined the project to be not feasible due to local discontent. Please also consider adding the decision regarding the Seven Mile project; impacts to the local community and the scenic area also could not be justified. [LTR 124, CMT 10]

Response: Comment acknowledged.

Comment: I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood area, along the Skamania and Klickitat county lines. I am concerned that the DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. [LTR 127, CMT 1]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: The EFSEC and BPA must consider other alternatives to the siting of the Whistling Ridge wind turbines to avoid marring the viewscape of the Gorge NSA! [LTR 130, CMT 1]

Response: Please see response to Comment LTR 79, CMT 1 above.
Comment: We feel it is imperative that the final EIS include alternatives such as adjusted placement or outright removal of the proposed A-array or however many wind turbines might be necessary to prevent any negative aesthetic impact to the nationally and globally recognized scenic area and its view points in the Columbia River Gorge. People come here to heal their souls and to escape from, not be impressed by, industrial complexes. [LTR 139, CMT 24]

Response: Please see response to Comment LTR 79, CMT 1 above.

Comment: The DEIS fails to address the potential expansion of the Whistling Ridge project onto Washington Department of Natural Resources public lands in Klickitat County. The applicant has previously indicated plans to expand the project into Klickitat County, and applied for a lease from DNR to do so. These plans should be evaluated as part of this project, rather than piecemealed for later consideration. [LTR 161, CMT 4]

Response: For the proposed action, the EIS evaluates what has been proposed to the lead agencies by the Applicant, as required by SEPA and NEPA. What has been proposed does not include development of any additional turbines on adjacent DNR land, nor does it include the interconnection of any additional power to the FCRTS. In addition, as discussed in Section 2.3.2 of the EIS, DNR is not interested in allowing development of wind turbines on the adjacent DNR land, regardless of any previously expressed wishes by the Applicant. Given this situation, not only is wind development of DNR land not part of the proposed action, it is also not considered reasonably foreseeable for the purposes of the cumulative impact analysis in the EIS.

Comment: The DEIS failed to evaluate alternatives to the proposal. SEPA and NEPA require consideration of alternatives. The applicant owns tens of thousands of acres of land, including other sites that would be more appropriate for wind power development than Whistling Ridge. The DEIS must evaluate potential alternatives, including alternative sites as well as alternative turbine layout configurations. [LTR 161, CMT 13]

Response: Please see response to Comment LTR 79, CMT 2 above.

Comment: I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood area, along the Skamania and Klickitat county lines. I am concerned that the DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. [LTR 163, CMT 1]
Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood area, along the Skamania and Klickitat county lines. I am concerned that the DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. [LTR 167, CMT 1]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood area, along the Skamania and Klickitat county lines. I am concerned that the DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. [LTR 169, CMT 1]

Response: Please see response to Comment LTR 66, CMT 1 above.
Comment: **SOLAR ENERGY FACILITY.** The DEIS discusses only the development of the site for wind energy facilities. The consideration of alternatives should be expanded to consider other alternate energy sources such as solar energy. Recently, a proposal for a 75 MW solar reserve has been made in Kittitas County (the Teamaway Solar Reserve, or “TSR”). The proposal will consist of approximately 145 acres for photovoltaic solar panels spread out over 900 acres. Such a proposal would reduce visual impacts and eliminate the noise impacts associated with wind turbine facilities, as well as eliminating the need for transportation of large towers and blades for wind turbines. This alternative should be fully considered in the DFEIS or FEIS. Thank you for this opportunity to comment on the DEIS. SOSA trusts that the FEIS will provide facts and analysis discussed herein. [LTR 175, CMT 7]

Response: The Applicant has proposed a particular type of energy generation source - wind energy - for the proposed Project. More fundamentally for EIS purposes, the need for action by the lead agencies is to consider an application and request for siting and interconnecting a proposed wind project, not some other type of generation or just renewable energy in general. Consideration of the proposed Teanaway Solar Reserve Project, which is an entirely different project proposed by others, would not be responsive to this need, and therefore is not considered as an alternative in the EIS.

Comment: Though this project has been under development for some time, the applicant has identified only a range of wind turbine generators which “would likely range in size from 1.2 to 2.5 MW.” DEIS at 1-9. However, the larger capacity turbines have larger diameter rotors (up to 100 meters), so it is unknown what the size of the machines would actually be. [LTR 176, CMT 2]

Response: Identification of a range of possible sizes of wind turbines is typical in a siting application for a proposed wind project, since the actual size to be used is not usually identified until the site certificate is issued. In addition, due to the high variability in potential turbine availability and pricing, it is currently unknown what turbines would be available when the Project is ready to be constructed (assuming it is approved), and the specific manufacturer and type of turbine that would be used thus cannot be determined at this stage in the Project review process. The specific manufacturer, type, and size of turbine will be identified at the time the site certificate is issued. However, as indicated in the EIS, it is reasonably expected that the turbines likely would range in size from 1.2- to 2.5-MW each, and would be up to approximately 426 feet from the ground to the turbine blade tip at its highest point. Thus, the EIS includes this turbine size range in its description of the proposed Project. If the 1.2-MW turbine were used, then up to 50 turbines would be installed, while if the 2.5-MW turbine were used, up to 30 would be installed. As discussed in Section 3.9.1.3 of the EIS, the visual impact analysis assumes use of the largest size turbine (2.5 MW) along with the maximum number of turbines (50) in order to assess the maximum envelope of potential visual impacts.

Comment: A severe deficiency in the EIS is the failure to consider any alternative other than the applicant’s minimum 70 MW proposal on its own property. Page 1-13 of the “Alternate
Project Locations” includes only sites within the ownership of SDS. On page 1-14, the EIS states that the applicant considered a lesser number of turbines, but rejected such an alternative because it did not fit within SDS’s concept of “economic feasibility.” The failure to consider either alternate locations or alternate site configurations (with fewer wind turbines) is a fundamental and fatal defect in the DEIS, as was previously pointed out at the public hearing on the document. The responsible official must prepare a supplemental DEIS to address and thoroughly consider reasonable alternatives. This supplemental DEIS should be circulated for comment in the same manner as any DEIS under NEPA/SEPA rules and regulations. [LTR 176, CMT 3]

Response: Please see response to Comment LTR 79, CMT 2 above.

Comment: The starting point for analysis of the alternative requirement is SEPA itself. RCW 43.21 C.030(1)(c)(iii) makes clear that the “detailed statement” (which is now the environmental impact statement requirement) must consider “alternatives to the proposed action.” Alternatives are so important under SEPA that each state agency, including EFSEC, has the responsibility to: Study, develop and describe appropriate alternatives to recommended courses of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources. The details of consideration of alternatives in an EIS is found at WAC 197-11-440(5). Under NEPA Rules, the consideration of alternatives is considered the heart of the EIS: Sec. 1502.14 Alternatives including the proposed action. This section is the heart of the environmental impact statement. Based on the information and analysis presented in the sections on the Affected Environment (Sec. 1502.15) and the Environmental Consequences (Sec. 1502.16), it should present the environmental impacts of the proposal and the alternatives in comparative form, thus sharply defining the issues and providing a clear basis for choice among options by the decision maker and the public. In this section agencies shall: (a) Rigorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated. (b) Devote substantial treatment to each alternative considered in detail including the proposed action so that reviewers may evaluate their comparative merits. (c) Include reasonable alternatives not within the jurisdiction of the lead agency. (d) Include the alternative of no action. (e) Identify the agency's preferred alternative or alternatives, if one or more exists, in the draft statement and identify such alternative in the final statement unless another law prohibits the expression of such a preference. (f) Include appropriate mitigation measures not already included in the proposed action or alternatives. As noted above, based on the applicant’s own opinion of financial feasibility, the DEIS has not considered other alternatives; a position which appears to be unquestioned by the drafters of the DEIS. However, the applicant has not provided any information on financial feasibility and cannot so stricture and limit its proposal to avoid alternatives. [LTR 176, CMT 5]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: It appears that the applicant asserts, and EFSEC and BPA concur, that the proposal is for a private project on private property. See 197-11-440(5)(d). This exemption
does not apply if the project includes a rezone or: if other locations for the type of proposed use have not been included or considered in existing planning or zoning documents. The portion of the DEIS addressing land use regulation does not disclose that wind turbines were ever included or considered in planning documents adopted in Skamania County. See DEIS at pages 3-140 to 3-155. [LTR 176, CMT 5]

Response: A Private Project, as defined in the SEPA Rules WAC 197-11-780, means any proposal primarily initiated or sponsored by an individual or entity other than an agency. The proposed Whistling Ridge Project meets this definition and is being reviewed as a private project. EFSEC believes the Applicant adequately considered alternatives to the proposed action, including alternative project locations, larger or smaller generation facilities, alternative wind generation technologies, alternative project configurations, and alternative interconnections, in Section 2.3 of the DEIS.

Comment: The failure of the DEIS to consider alternatives is a fatal flaw for several reasons. First, there are serious issues as to whether the proposal is consistent with local zoning. While the DEIS seems to claim that the project is consistent with Skamania County’s comprehensive plan and zoning code, there are many reasons to believe it is not. On May 6, 2009 SOSA filed a lengthy letter directed to both Skamania County and EFSEC challenging the consistency of the proposal with local zoning. Among other matters, that letter pointed out that wind turbines or wind farms are not listed as permitted uses in the Skamania County Zoning Ordinance or in the 2007 Skamania County Comprehensive plan. The latter conclusion is confirmed by decision of the Skamania County Hearing Examiner made in February 2009 in a SEPA challenge to a determination of non-significance for adoption of a new zoning ordinance for Skamania County, which ordinance proposed regulating wind turbine development. Questions arose during the course of that hearing regarding whether the 2007 Skamania County Comprehensive Plan actually permitted or considered wind energy facilities. In her decision, the Hearing Examiner found as follows: The 2007 Comprehensive Plan does not contemplate the type of energy facilities described in the Planning Commission Recommended Draft. See Findings and Decision, Finding 18 at page 8. The Hearing Examiner went on to rule that Skamania County was required to prepare an environmental impact statement prior to the adoption of its new zoning ordinance. Skamania County has never prepared the environmental impact statement ordered by the Examiner and the proposed zoning ordinance was not adopted. Since Skamania County has adopted a zoning ordinance that does not provide for wind energy facilities, and its comprehensive plan does not contemplate such facilities, the exception in the SEPA Rules does not apply. Either WRE must apply for a rezone (which it has not) or EFSEC must preempt local zoning. The preemption decision by EFSEC would be the functional equivalent of a rezone because it provides approval for a previously unpermitted use. In fact, EFSEC must make a determination of land use consistency and held a hearing on that subject on May 6, 2010. However, EFSEC did not make a decision on land use consistency at that time and has deferred such decision to be made in the course of the adjudicative hearings. The consistency of the proposed project with local zoning has yet to be determined. The responsible official under SEPA, the EFSEC manager, accordingly cannot determine whether the WRE project is consistent with local zoning. If it is not, the Council may preempt local zoning, which would be
the functional equivalent of a rezone for the project. Alternatives must accordingly be fully considered. [LTR 176, CMT 6]

Response: Please see response to Comment LTR 176, CMT 5 above.

Comment: Second, the proposal is not a private project within the meaning of the SEPA Rules. This issue was previously considered in a Washington Supreme Court decision: Under the present statutes and administrative code, the question now before the court as to whether the EIS is adequate turns on whether the proposed project is a “public project” or a “private project.” It is unnecessary in this case to determine whether the “public”/ “private” distinction drawn in the administrative code accords with SEPA policy. We recognize that one commentator has suggested that in certain cases, the distinction may be unsound. See Richard L. Settle, The Washington State Environmental Policy Act: A Legal and Policy Analysis § 14(b )(ii) (4th ed. 1993). WAC 197-11-440(5)(d) provides in relevant part: When a proposal is for a private project on a specific site, the lead agency shall be required to evaluate only the no action alternative plus other reasonable alternatives for achieving the proposal’s objective on the same site... A “private project” is defined in WAC 197-11-780: “‘Private project’ means any proposal primarily initiated or sponsored by an individual or entity other than an agency.” Weyerhaeuser v. Pierce County, 124 Wn. 2d 26, 38-39, 873 P.2d 498, 505 (1994). The project in Weyerhaeuser was a land fill proposed by a private applicant on private property. However, the court concluded it was a public project because of the close relationship between the county actions and the supposedly private project. The court went on to hold: We agree with the Weyerhaeousers that, as a matter of law, the proposed landfill is a public project, and the EIS must contain a sufficient discussion of offsite alternative proposals. Because it does not do so, it is inadequate as a matter of law. The WRE project is similarly public for several reasons. First, the DEIS contains extensive discussion as to need for electric power to meet public needs for the region. See DEIS pages 1-4 to 1-7. This is clear in the DEIS at page 1-4: “The Applicant’s purpose in proposing the Whistling Ridge Energy Project is to help meet the future need for energy resources.” SDS also seeks to provide an additional renewable resource for electric utilities in Washington. Second, this project has been referenced by its proponents as a “semi-public” facility under the Skamania County zoning ordinance. See DEIS at page 3-147 to 149. The WRE proposal is not exempt from alternatives analysis under SEPA or NEPA as it must be classified as a public facility. [LTR 176, CMT 7]

Response: Please see response to Comment LTR 176, CMT 5 above.

Comment: Seventh, in examining alternatives, the draft needs to compare the impacts of developing the proposed project with other alternate sources of wind energy being developed within the jurisdiction of EFSEC. There are serious impacts related to the WRE proposal based largely on its location. The Underwood location will have serious visual and aesthetic impacts to extremely valuable and unique scenic resources found in the Columbia River Gorge, where because of its elevation the project will be seen by many persons over a broad area. Further, this forested location increases substantially the risks of bird and bat collisions with the turbine
blades. Other environmental impacts are of concern because of the location of the turbines on steep ridgelines, which may restrict options for micrositing and increase impacts due to road building. This location should be compared with other possible sites, especially in southeast Washington where wind turbines are located away from populated areas and have lesser risk for bird or bat collisions. [LTR 176, CMT 14]

Response: Please see response to Comment LTR 79, CMT 2 above.

Comment: Eighth, the section on alternatives in SEPA explicitly calls for an analysis of the alternative of future development of the proposal under WAC 197-11-440(5)(c) where the alternatives section of the EIS includes obligation to: (vii) Discuss the benefits and disadvantages of reserving for some future time the implementation of the proposal, as compared with possible approval at this time. The agency perspective should be that each generation is, in effect, a trustee of the environment for succeeding generations. Particular attention should be given to the possibility of foreclosing future options by implementing the proposal. For the present application, the DE IS must discuss the alternative of delaying the implementation of the WR proposal. In light of visual impacts, bird and bat kills and other serious impacts of the WR proposal, the DEIS should discuss the option of reserving the WRE project until such time as projects with lesser impacts have been permitted and constructed. The DE IS should accordingly discuss potential wind turbine sites, including those permitted, those under application, and those in areas where new applications are likely, for example, where land commitments in the form of leases are made by property owners to wind turbine developers. [LTR 176, CMT 15]

Response: Neither SEPA nor NEPA require that the option of merely delaying implementation of a proposed project be treated as an entirely separate and distinct alternative in an EIS. As noted in the comments, SEPA does require consideration of the benefits and disadvantages of delaying a proposed project in an EIS. Accordingly, this consideration has been included in Section 2.4 of the EIS. The lead agencies believe that this section provides a fair discussion of the benefits and disadvantages of delaying this proposed Project. Nonetheless, Section 2.4 of the EIS has been revised to better reflect that some of the identified disadvantages would be delayed rather than entirely prevented.

Comment: Ninth, the proposed project requires an interconnection with the BPA transmission line together with the construction of a substation. That is clearly a public project, not a private project, and thus alternatives must be fully considered. As related to the substation it is understood that the BPA substation must be built with capacity to receive additional electric energy for interconnection with the FCRTS. Thus, the EIS must consider whether the BPA substation will act as an attraction for other energy projects to locate nearby. In this regard, SOSA notes that a natural gas pipeline traverses the north portion of the project area. See DEIS, Figure 2-3. In the recent past, the land owner SDS has promoted plans for a gas turbine for electrical generation in this area. The EIS must consider the possibility of a gas turbine project in the area, especially one that may have enhanced financial feasibility because of the
proximity to both a fuel source (the gas pipeline) and a substation to connect that energy to the FCRTS. Given the need for balancing resources for VERs like WR, location of such a facility nearby appears more likely. Accordingly, the EIS must consider the impacts of such a gas turbine facility, including air emissions, noise, wildlife impacts and other impacts common to these facilities. [LTR 176, CMT 16]

Response: Please see response to Comment LTR 176, CMT 5 above.

Comment: Tenth, while SEPA contains the public v. private distinction, NEPA and the NEPA Guidelines contain no such exception. Since this DEIS is to meet NEPA requirements, there must be a full exploration of available alternatives under the terms of both NEPA and SEPA rules. As cited above, the NEPA Guidelines require consideration of alternatives even though they may not be within the agency’s jurisdiction. Given the importance of alternatives analysis under both NEPA and SEPA, the failure of EFSEC and BPA to do this analysis now may mean that upcoming processes will have to be repeated should a court determine that the procedure adopted is illegal, resulting in a huge waste of time and resources of all involved. [LTR 176, CMT 18]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: In summary, the failure of the DEIS to discuss reasonable alternatives is a fatal flaw in that document. EFSEC and BPA should immediately withdraw the noncompliant DEIS and prepare a supplemental DEIS that considers all reasonable alternatives, not just those identified in this letter. The supplemental DEIS should be circulated for comment as required for any DEIS and no work on the final EIS should begin until all comments are in for the supplement. [LTR 176, CMT 19]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: The FEIS should also be expanded to consider the Middle Mountain Project, which is only 12 miles from the proposed project site, as an alternative wind generation site. [LTR 177, CMT 9]

Response: The EIS addresses the need for the lead agencies to respond to an application and request by the applicant for a proposed wind project to be developed by the Applicant. Consideration of the Middle Mountain Wind Project, which is an entirely different project that has been proposed by Hood River County, Oregon would not be responsive to this need, and therefore is not considered as an alternative in the EIS. While the Middle Mountain Wind Project was included in the DEIS cumulative impact analysis, Section 1.8.1.2 in the FEIS has been revised to explain that the Hood River County Commission decided to cease efforts to pursue the Middle Mountain project (around 10 MW) at its meeting on May 17, 2010.
Comment: [In reference to DEIS Section] 2.0, Proposed Action and Alternatives, [Section] 2.1, PROPOSED ACTION, [Section] 2.1.2, Project Overview, Table 2-1: Permanent disturbance areas should include the permanent parking areas adjacent to each turbine that will be necessary to conduct turbine repairs and maintenance. Also there appears to be some inconsistency in the road width used to determine the impact area outside the project. [In Section] 2.1.3.7, Access Roads, [n]either the Application nor the DEIS include a description of parking areas that will have to be maintained adjacent to each turbine for construction and maintenance purposes. The space consumed by these parking areas should also be included in the calculations for permanently disturbed environment. [LTR 177, CMT 17]

Response: The areas of disturbance for maintenance vehicle parking and turnarounds is included in the temporary and permanent disturbance acreage for Turbine String Corridor listed in Table 2-1 on page 2-4 of the DEIS. Regarding the width of access roads outside the Project Area, page 2-8 and page 3-215 of the DEIS both state the existing width of West Pit Road is 20 to 26 feet. Portions of approximately 2.5 miles of West Pit Road would be widened to create a drivable surface of 25 feet with 5 feet of additional clearing on each side.

Comment: [In reference to DEIS Section] 2.3.6, Alternative Access Roads, [please refer to earlier] comments in response to Section 1.4.3.6, Alternative Access Roads. [LTR 177, CMT 17]

Response: Use of CG 2930 was evaluated in the original Application for Site Certification as “Route 2.” This route would have connected the site to Cook-Underwood Road via Kollock-Knapp Road, Scoggins Road and CG2930. CG2930 is a private logging road that crosses property owned by the Applicant and is currently used for commercial timber production and harvest. As described in Section 2.3.6 on DEIS page 2-23, use of Route 2 would require minor roadway improvements that would not directly impact any non-Project landowners. However, these roadway improvements would require construction within the National Scenic Area. Therefore, Route 2 was eliminated as a construction roadway access alternative purpose and need for proposed action, or clearly greater environmental impacts.

Comment: [In reference to DEIS Section] 2.1.4.1, Construction, [t]he size and location of proposed laydown areas should be disclosed and evaluated in the FEIS. The size and location of permanent parking lots next to each turbine should be included and evaluated in the FEIS. This section should include a discussion regarding how concrete will be transported to the construction site. If a concrete batch plant is going to be used, its size and location should be disclosed in the FEIS. If concrete is going to be transported to the site, information regarding the trucking route and potential environmental impacts (air pollution, traffic, etc.) should be disclosed and evaluated in the FEIS. [In reference to Section] 2.1.6, Forest Harvest, [d]uring Project Construction and Operation Mitigation measures for construction of the project should include off-site mitigation for permanently disturbed or cleared areas that would constitute “forest conversions.” This would include turbine parking areas and any permanent laydown area at the site. [LTR 177, CMT 18]
Response: The areas of disturbance for temporary laydown areas and maintenance vehicle parking and turnarounds was included in the temporary and permanent disturbance acreage for “Turbine String Corridor” listed in Table 2-1 on page 2-4 of the DEIS. These Project features would be located within the 650-foot wide micrositing corridor. As stated in Section 3.8.5 (DEIS, Page 3-155) the 1,152-acre Project Area would continue to be predominantly used for commercial forestry operations. A maximum of approximately 56 acres of forestry land (under 5 percent of the Project Area) would be converted to energy facility use for the life of the Project. This conversion would not constitute a substantial change to area land use patterns given the area of the Project retained for active forestry operations, and given the acreage surrounding the Project in both private and state ownership that will be maintained in commercial forestry operations. As described in Section 2.14.3 of the Application for Site Certification, the use of on-site batch plants are under consideration. However, if concrete needs to be transported to the site, concrete trucks would use the same haul routes used to transport the large turbine components. See Section 1.4.1.6 of the EIS for a description of the proposed haul route.

Comment: [In reference to DEIS Section] 2.1.7, Project Decommissioning. [t]he Applicant has indicated that the life of the project is expected to be 30 years, at which time the project will either be upgraded (“re-powered”) or decommissioned. If the current project receives EFSEC approval, any proposal to “re-power” the project or extend operation of the project beyond its anticipated life span should be reviewed by EFSEC as an amendment to the Site Certification Agreement. Such review should require an updated evaluation and assessment of the environmental impacts posed by the upgrade or extended life of the project. [LTR 177, CMT 19]

Response: Section 2.1.7 of the EIS includes information concerning potential future decommissioning and site restoration that is reasonably foreseeable at this time. Given that these activities would occur 30 or more years into the future, it is not currently known what types of technologies or techniques would be available at that time to best accomplish decommissioning and site restoration. Any specific plan developed at this time thus would be not only speculative, but also could be viewed as limiting these activities to only currently available technologies and techniques. As discussed further in Section 2.1.7, any future decommissioning and site restoration would be conducted in accordance with applicable state laws, which would include an assessment of potential impacts from these activities. To the extent that EFSEC has authority over possible actions taken to “re-power” the Project in the future, these actions also would be subject to appropriate environmental review.

Comment: [In reference to DEIS Section] 2.4, BENEFITS AND DISADVANTAGES OF DELAYING PROJECT IMPLEMENTATION. This section summarizes the benefits and disadvantages that will result from delaying the project. It is drafted, however, in a way that minimizes the benefits and over-exaggerates the disadvantages of delay. For example, statements to the effect that a delay will prevent the creation of new construction jobs are simply not accurate. A delay in constructing the project will result in a delay in the creation of new construction jobs, just as a delay in constructing the project will delay visual impacts from the project. [LTR 177, CMT 22]
Response: Please see response to Comment LTR 176, CMT 15 above.

Comment: [In reference to Section] 2.5, COMPARISON OF ALTERNATIVES. Government action or inaction is not the only possible reason that the project will not be built. For the reasons discussed earlier, assertions that the No Action Alternative will only arise if EFSEC or BPA deny approval of the project should be redacted. [LTR 177, CMT 23]

Response: Comment noted. It is acknowledged that many factors could result in the Project not being built, and nothing in the EIS is intended to indicate that project disapproval by the lead agencies - EFSEC and BPA - would be the only reason the Project may not be built. Nonetheless, for the purposes of defining the No Action alternative in the EIS, the key consideration is what the result would be if the either or both of the lead agencies decide not to approve the proposed project. Thus, the EIS references the No Action alternative in this manner

Comment: As discussed above, the DEIS should be expanded to include off site and on site alternatives. Without these additional alternatives, the comparison of the limited alternatives set forth in Table 2-5 is of questionable value for purposes of conducting meaningful environmental impact analysis under NEPA and SEPA. [This expansion of off-site and on-site alternatives should be expanded to Section] 3.0, Affected Environment, Impacts and Mitigation, [where g]enerally, discussions in this section should be expanded to include off site and on site alternatives. [LTR 177, CMT 23]

Response: Please see response to Comment LTR 79, CMT 2 above.

Comment: Applicant-owned land that contained high ridges on which to place wind turbines with little impact to the continued underlying use of the land for commercial forestry. Applicant states in DEIS that commercial forestry would cease for the life of the Project. Plus, why are high ridges mutually exclusive for wind, this is not true for most all Projects in Eastern WA and OR. Note: this citation is one of 3 KEY criteria for establishing a site. It is flawed in logic, and will bias the conclusion that only the proposed site is feasible. Remedy - The Alternatives analysis must be redone with the criteria removing the requirement of placement on a high ridge, as this artificially excludes viable lands. Remove the limitation of placement only in areas used for commercial forestry. [LTR 178, CMT 40]

Response: The requirement for high ridges for the Project is a product of the topography in the Project Area and surrounding area. This topography generally consists of relatively sharp ridges and valleys, as compared to the more rolling hills and landscape of eastern Washington and Oregon. In general, wind blows more frequently and strongly at the top of the ridges in the Project vicinity, rather than in the valleys. Thus, in order to be able to utilize this wind resource, turbines would need to be location generally on the ridges. The discussion concerning
commercial forestry is intended to reflect the desire not to unduly interfere with land that is currently in that use.

Comment: [In reference to] Section 2.3, [t]he project must be located in an area with a steady supply of robust wind power, and on a site on which construction can reasonably occur (no significant geotechnical constraints). Both terms “steady” and “robust” have not been substantiated with independent data, or data from the Applicant. (i.e. met tower data in velocity, durations, 3-Dimensional directions). The DEIS does not even demonstrate that the “preferred” alternative meets these criteria. Remedy - 1) Quantify the terms “steady” and “robust.”  2) Support the “preferred” alternative with data compared to item 1 above.  3) Evaluate other alternatives against the standards established in item 1 above. [LTR 178, CMT 63]

Response: The purpose of the EIS that has been prepared is to evaluate the potential environmental impacts that could occur from the lead agencies’ actions concerning the proposed Project, not to require financial or resource justification for the proposed Project itself. In other words, neither SEPA nor NEPA require that an EIS prove or validate the applicant’s business case for its proposal.

Comment: [In reference to] Section 2.3, [t]he project must be located in an area with a steady supply of robust wind power, and on a site on which construction can reasonably occur (no significant geotechnical constraints). The micrositing corridor for proposed Turbines A1-7 averages ONLY 170 feet wide, before entering into Landslide Hazard Area (LHA) Class II. The URS report (DEIS at Appendix B) states no Turbines will be sited on LHA Class II (or I, implied) soils. With a Foundation diameter of 60 feet (typ.) there is very limited ability to site these machines. The Applicant’s “preferred” alternative does not even qualify for consideration, according to their own standards. Remedy - Since no other alternatives have been offered, other than the No Action alternative, one or two other Alternatives must be added to compare the reasonableness of construction from a geotechnical perspective. [LTR 178, CMT 65]

Response: The Applicant believes, and the lead agencies agree, that based on available geotechnical information, the Project as proposed can be sited to avoid significant geological hazards. Additional alternatives related to geotechnical constraints thus are not necessary.

Comment: [In reference to] Section 2.3, [t]o reduce startup costs, the project must be located on land the Applicant owns and controls, and land that can serve a dual purpose of commercial forestry and power production. Generally speaking, most Land Lease agreements are based more on output, than on fixed rates, and they may or may not include up front costs. These are an insignificantly low percentage of the construction costs (read “startup costs”) that this argument can only speak to the marginal economic viability of this project. As for land that can serve a dual purpose of revenue generation over the life of the project, similar to wheat farming, this has NOTHING to do with STARTUP COSTS. These are self serving, self-imposed

G-87
constraints, designed to artificially restrict consideration of any other alternative. Remedy - Disclose financial justification of how these particular startup costs materially effects project viability, or remove that as a “constraint” in evaluating Alternatives. [LTR 187, CMT 66]

Response: The purpose of the EIS that has been prepared is to evaluate the potential environmental impacts that could occur from the lead agencies’ actions concerning the proposed Project, not to require financial or resource justification for the proposed Project itself. In other words, neither SEPA nor NEPA require that an EIS prove or validate the applicant’s business case for its proposal.

Comment: [In reference to] Section 2.3, [in order to] enable the power to reach urban markets and eliminate the cost and time required to construct new transmission lines, the project must be located in proximity to existing high-voltage transmission lines. Proximity to existing high-voltage transmission lines is PURELY a matter of economics, and has nothing to do with power reaching urban markets. Remedy - Restate the “constraint” to incorporate the additional costs, due to this factor, into the potential viability of other alternatives. Such that the economic viability of WRE has a certain savings over Alternative B, C, and D, for example. [LTR 178, CMT 67]

Response: For further discussion of the Project’s purpose and need and alternatives, see Section 1.2.3.

Comment: General Comment on DEIS. BPA yard size of 4+ acres invites and encourages future growth, which must be evaluated now. Remedy - BPA must, or the DEIS must, identify the minimum size of land needed to house a 75 Megawatt Substation, and only permit, purchase, and develop such a BPA Facility, if the proposed WRE project is approved. Any larger size of land or power capacity would trigger additional review requirements for WRE Application in the BPA NEPA process. [LTR 178, CMT 133]

Response: The proposed BPA substation to interconnect the proposed Project is sized to accommodate only the interconnection of this Project. Interconnection of other generation projects at this substation is not envisioned or planned at this time. Nonetheless, if any proposal materializes at some future time for a potential generation interconnection at this substation, and if such a proposal appears feasible from a technical and operational standpoint, BPA would consider such a proposal and would conduct appropriate NEPA review of the proposal at that time.

Comment: As in the National Parks & Conservation Association case, the private economic interests of the Applicant are the driving force behind the purpose and need statement, and thus behind the entire DEIS. The narrowly drawn statement unreasonably constrains the possible range of alternatives, because it excludes alternatives that fail to meet the Applicant’s specific private objectives, which are to build a wind energy project. The result of such a narrowly
driven statement led to only two alternatives to be considered: the proposed action (authorizing construction and operation of the proposed Whistling Ridge Entergy Project and associated components) and the No Action Alternative (not authorizing construction and operation of the proposed project). This extremely narrow range of alternatives is unreasonable, and thus, violates NEPA. [LTR 179, CMT 18]

Response: EFSEC and BPA have identified their respective need for action in a manner entirely consistent with SEPA and NEPA. As discussed in Section 1.2.1 of the EIS, EFSEC’s need for action is to respond to an application by WRE for a site certificate. As discussed in Section 1.2.2 of the EIS, BPA’s need for action is to respond to WRE’s request for an interconnection of its proposed Project to the Federal Columbia River Transmission System (FCRTS). Each agency also has separate purposes (i.e., objectives) that it will bear in mind and attempt to meet in reviewing and making a decision on the Project. Given the agencies’ need for action in this case (i.e., to approve or deny an application and request), the range of alternatives considered in detail in the EIS is not unreasonable. In addition, the agencies considered a number of other alternatives but eliminated those alternatives from detailed study in the EIS, as discussed in Section 2.3.

Comment: The Range of Alternatives Considered is Inadequate. The DEIS discusses only the Proposed Action Alternative (the proposed project) and the No Action Alternative. Such a truncated alternatives analysis violates the agencies’ duties under NEPA and SEPA to fully review all reasonable alternatives. “The purpose of NEPA is to require disclosure of relevant environmental considerations that were given a ‘hard look’ by the agency, and thereby to permit informed public comment on proposed action and any choices or alternatives that might be pursued with less environmental harm.” Te-Moak Tribe of Western Shoshone of Nevada v. United States Dep’t of the Interior, ---F.3d ---, 2010 WL 2431001 (9th Cir. 2010) (quoting Lands Council v. Powell, 395 F.3d 1019, 1027 (9th Cir.2005)); see also 42 U.S.C. § 4332(E) (requiring agencies to “study, develop, and describe appropriate alternatives to recommended courses of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources”). Agencies are required to consider alternatives in an EIS and must give full and meaningful consideration to all reasonable alternatives. Id.; see also 40 C.F.R. § 1508.9(b). “The existence of a viable but unexamined alternative renders an environmental impact statement inadequate.” Id. (citing Idaho Conservation League v. Mumma, 956 F.2d 1508, 1519 (9th Cir.1992) (quoting Citizens for a Better Henderson v. Hodel, 768 F.2d 1051, 1057 (9th Cir.1985)). SEPA also requires an EIS to evaluate alternatives. RCW 43.21C.030(2)(c)(i). The applicable guidelines are found at WAC 197-11-440(5). An alternative considered for purposes of an EIS need not be certain or uncontested, it must only be reasonable. King County v. Central Puget Sound Growth Management Hearings Bd. 138 Wn.2d 161, 184-85, 979 P.2d 374, 385 (1999). A reasonable alternative is one that could feasibly attain or approximate a proposal’s objectives at a lower cost to the environment. Id.; see also WAC 197-11-440(5)(b). According to the applicable federal regulations, an EIS “shall inform decision-makers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment.” 40 C.F.R. § 1502.1. CEQ clarified the meaning of this requirement in its “Forty Most Asked Questions” policy guidance by defining “reasonable alternatives” as including “those that are practical or feasible from the
technical and economic standpoint and using common sense, rather than simply desirable from the standpoint of the applicant.” Forty Most Asked Questions Concerning CEQ’s National Environmental Policy Act Regulations, 46 Fed. Reg. 18,026 (Mar. 23, 1981) (emphasis in original). When selecting alternatives, an agency may consider an applicant’s desires, but is not by any means bound or limited by them. It is not appropriate for an agency to rely on the “self-serving statements of the project applicants.” Southern Utah Wilderness Alliance v. Norton, 237 F. Supp. 2d 48, 53 (D.D.C. 2002). Instead, the action agency must “to the fullest extent possible ... study, develop and describe appropriate alternatives to recommended courses of action in any proposal which includes unresolved conflicts concerning alternative uses of available resources.” Id. at 54 (citing 42 U.S.C. § 4332(2)(E)). Moreover, “[o]ther factors [other than the applicant’s desires] to be developed during the scoping process - comments received from the public, other government agencies and institutions, and development of the agency’s own environmental data - should certainly be incorporated into the decision of which alternatives to seriously evaluate in the EIS.” CEQ, Guidance Regarding NEPA Regulations, 48 Fed. Reg. 34,263, 34,267 (July 28, 1983). [LTR 179, CMT 20]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: Again, the DEIS analyzes the impacts of only two alternatives: 1) the proposed project, and 2) the no action alternative. These options advance the Applicant’s goals, rather than the agencies’ goals, to the exclusion of other reasonable alternatives. The DEIS is fatally flawed in its failure to consider an adequate range of reasonable alternatives. See Muckleshoot Indian Tribe v. USFS, 177 F.3d 800, 913 (9th Cir. 1999) (agency failed to consider an adequate range of alternatives when an EIS considered only a no action alternative along with two “virtually identical” action alternatives). [LTR 179, CMT 21]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: Various other alternatives should have been considered. First, at page 1-13 of the DEIS, the BPA did not consider any alternate locations for the wind turbine project other than those owned by the Applicant. Likewise, alternatives for interconnecting the wind project with transmission lines off of the project site were eliminated. Indeed, under NEPA, the EIS may even have to look at alternatives over which the applicant has no control. NRDC v. Morton, 458 F.2d 827, 835 (D.C. Cir. 1972); NWF v. NMFS, 235 F. Supp.2d 1143 (W.D. Wash. 2002). Further, it is irrelevant whether an applicant already owns alternative sites for the purposes of NEPA review: “The fact that this applicant does not now own an alternative site is only marginally relevant (if it is relevant at all) to whether feasible alternatives exist to the applicant’s proposal.” Van Abbema v. Fornell, 807 F.2d 633, 638 (7th Cir. 1986). As stated in the Van Abbema case, other alternatives for a project cannot be eliminated as non-feasible simply because the Applicant does not now own the site where an alternative location may exist. Here, SDS and Broughton Lumber own tens of thousands of acres of land in Oregon and Washington that could potentially be available for energy production purposes. The EIS fails to consider those lands, and fails to consider the possibility of applicant purchasing lands in other
locations, such as east of the National Scenic Area, for an energy facility. Similarly, SEPA also requires a discussion of alternate development sites for a proposed project in order to have an adequate discussion of reasonable alternatives. See Barrie v. Kitsap County, 93 Wn.2d 843, 855, 613 P.2d 1148, 1155 (1980) (EIS was inadequate because it looked only at the use of the applicant’s private property for siting a shopping center, and failed to discuss alternative development sites). Here, alternate locations could provide comparable energy output. This approach would be consistent with the BPA’s stated goals of acting consistently with its environmental and social responsibilities and providing for cost and administrative efficiency. Surely other sites with far less impacts could easily be located. Not far to the east of this project site, thousands of wind turbines have been constructed recently, the vast majority of which pose far less resource impacts than the Whistling Ridge site. [LTR 179, CMT 22]

Response: Please see response to Comment LTR 79, CMT 2 above.

Comment: Another potential site is immediately north of the proposed project site, on DNR lands. In fact, this property has been designated by WRE as “Phase 2” of the Whistling Ridge project. Although DNR has indefinitely placed on hold consideration of WRE’s request for a wind power lease of this property, that does not mean use of the property is forever out of the question. In fact, recent emails by WRE representatives, obtained by Skamania County residents Keith Brown and Teresa Robbins in response to a public records request, indicate that WRE still wishes to use the DNR property for wind energy. The DEIS fails to analyze the possibility of siting wind turbines on this property rather than on the SDS and Broughton Lumber land. Second, the BPA did not consider alternate configurations (with fewer wind turbines and/or in different locations) for the project. [LTR 179, CMT 23]

Response: Please see response to Comment LTR 161, CMT 4 above.

Comment: On page 1-14, the DEIS states that “the project must be capable of producing a minimum of 70 MW” and that the project size “was selected to optimize . . . economic feasibility” (emphasis added). There are no financial data or projections provided to support this claim. Moreover, the agencies eliminated any alternatives that would have considered a smaller generation facility, for instance in order to address potential environmental impacts, solely in an effort to “optimize”2 [Footnote 2: The Webster’s Dictionary definition of “optimize” is “to make as effective, perfect, or useful as possible.”] the applicant’s economic wishes. Nor did the agency consider alternative locations for individual turbines that would reduce their impacts. This approach is unlawful and violates the agencies’ legal mandates. [LTR 179, CMT 24]

Response: Please see response to Comment LTR 79, CMT 1 above.
Comment: Fourth, no conservation alternatives were considered to eliminate the stated “need” for this 70 MW of installed capacity. Conservation alternatives, such as demand response technologies, also should have been included in order to meet the agencies’ goals of promoting their environmental and social responsibilities. [LTR 179, CMT 26]

Response: Please see response to Comment LTR 33, CMT 6 above.

Comment: Fifth, another reasonable alternative is one that analyzes and considers the future development of the proposal. WAC 197-11-440(5)(c) states that the EIS shall: (vii) Discuss the benefits and disadvantages of reserving for some future time the implementation of the proposal, as compared with possible approval at this time. The agency perspective should be that each generation is, in effect, a trustee of the environment for succeeding generations. Particular attention should be given to the possibility of foreclosing future options by implementing the proposal. The DEIS fails to comply with this requirement, because it fails to consider the possibility of delaying the development of wind energy until a later date, perhaps at a time when the energy grid will be more equipped to handle the addition of new wind energy sources. [LTR 179, CMT 27]

Response: Please see response to Comment LTR 176, CMT 15 above.

Comment: The above alternatives were either eliminated from the study, or not considered at all, because the Applicant’s economic needs, rather than the stated goals of the agencies, dictated the results of this DEIS. In effect, the agencies are violating their duties to consider all reasonable alternatives. [LTR 179, CMT 28]

Response: Please see response to Comment LTR 179, CMT 18 above.

Comment: Third, what turbines will be used and how large will they be? The scale of commercial turbines continues to increase year by year. Taller turbines than the ones depicted would be even more visible and higher contrast. [LTR 180, CMT 27]

Response: Please see response to Comment LTR 176, CMT 2 above.

Comment: We respectfully request that the DEIS and the Final EIS include consideration of the following alternatives which are absent or rejected in the DEIS: 1. Resiting of the seven most southerly “A Towers” (A1-A7) to a location within the proposed site that mitigates negative impacts; 2. Use of towers across the project with greater megawatt per tower ratings that will allow for the elimination of Towers A1-A7 with minimal impact on the proponents total megawatt output target of 75 MW; 3. Use of low profile towers across the project, and in
particular at tower locations A1-7 to minimize negative impacts; 4. Elimination of towers A1-A7 through micro-siting across the project as a whole; 5. Elimination of towers A1-A7 to mitigate negative impacts. Such alternatives should be considered in the DEIS and the Final EIS to mitigate negative impacts based on the following five facts: 1. That tourism is the life blood of Skamania County and all communities throughout the Columbia River Gorge; 2. That Agri-Tourism is the present day driver of tourism in the famous Hood River Valley and that Underwood is well on its way to duplicating that economic success in Eastern Skamania County; 3. That Underwood’s historic transformation from pear orchards to Agri-Tourism and to one of the premier wine producing regions in the world has enormous present-day socio-economic value; 4. That the very real present-day economic value of Underwood Agri-Tourism, as well as its future potential, would be severely impacted by the seven “A Towers” as currently sited; and finally 5. That this Council has the authority and responsibility to put the reins on this project by requiring the responsible re-siting or elimination of the seven “A Towers”; towers that will otherwise dominate the skyline and become Underwood’s new “calling card.” As we detail in our written comments, failure to re-site the seven “A Towers” would improperly force the blossoming Underwood Agri-Tourism industry to bear a disproportionate share of the negative environmental and socioeconomic impacts of this project in violation of WAC 463-60-085. Such a result is prohibited by WAC 463-47-110 which states that “[t]he overriding policy of the council is to avoid or mitigate adverse environmental impacts which may result from the council’s decisions.” [LTR 186, CMT 3]

Response: Please see response to Comment LTR 79, CMT 1 above.

Comment: For the reasons set forth above, we respectfully request that the DEIS and the Final EIS include consideration of the following alternatives which are absent or rejected in the DEIS: 1. Resiting of the seven most southerly “A Towers” (A1-A7) to a location within the proposed site that mitigates negative impacts; 2. Use of towers across the project with greater megawatt per tower ratings that will allow for the elimination of Towers A1-A7 with minimal impact on the proponents total megawatt output target of 75 MW; 3. Use of low profile towers across the project, and in particular at tower locations A1-7 to minimize negative impacts; 4. Elimination of towers A1-A7 through micro-siting across the project as a whole; and 5. Elimination of towers A1-A7 to mitigate negative impacts. [LTR 186, CMT 18]

Response: Please see response to Comment LTR 79, CMT 1 above.

Comment: The Meteorological Towers should neither be a basic design nor a lattice design. The Meteorological Towers should utilize a Tubular towers; pursuant to the same justification for turbine towers. Construction of a Tubular Meteorological Tower may require a Custom design, in that the top of the tower would have to be adapted to support the equipment it supports. [LTR 193, CMT 3]

Response: We believe that the commenter is assuming that there might be some avian issues associated with lattice met towers as there were associated with lattice turbines towers in the
past. This is not the case. First, the permanent lattice met towers are smaller in diameter than
the lattice towers that historically were used for wind turbines. Second, these permanent lattice
met towers in the vicinity of the Project would provide no greater perching potential for birds
than existing trees in the vicinity of the Project. Industry standard practice is to use lattice met
towers because they do not require multiple guy wires for support. Tubular towers are available
for use, but they would require nine or more guy wires to support them from blowing down and
require frequent tightening and maintenance. In the case of the forested Whistling Ridge site, if
tubular towers were used with guy wires it will increase the amount of cleared area that would be
required for the Project because trees cannot be allowed to grow in a large radius around the met
tower. The cleared area is necessary to prevent tree interference with the guy wires. Lastly,
permanent lattice met towers would be located in the Project vicinity but not immediately
adjacent to the wind turbines or in a location where they can cause interference or cause an
elevated risk of avian strikes.

Comment: Please reconsider other SDS properties to post wind towers. The ridges east of
White Salmon are preferable, but frankly, all towers should be east of Lyle. Thank you for your
time and consideration. [LTR 210, CMT 3]

Response: Please see response to Comment LTR 79, CMT 2 above.

Comment: However, I do feel that if the project managers can make some minor
modifications to number or exact location of the towers to accommodate specific complaints of
the local residents, they should do their best. [LTR 212, CMT 4]

Response: Please see response to Comment LTR 79, CMT 1 above.

Comment: If you allow these towers on the rim of the Gorge, you are setting a precedent in
the Gorge. On what grounds could you deny any others near the Gorge? This will lead to all
the rims of the Gorge, at least on the WA side, being lines with towers, since the wind is good
everywhere. In turn, that may break down the objections to towers on the OR side. [LTR 262,
CMT 1]

Response: It is unclear at this time whether approval of the proposed Project would set a
precedent for siting other wind projects in the area. Since all projects are evaluated on a case-by-
case basis, approval of this Project does not dictate that any other Project that may be proposed
in the future would also be approved. In addition, most developers are aware of the challenges
of attempting to site wind projects in this general area. For the Applicant, proposing a wind
project in this area may make sense, but other wind project developers may have differing
opinions. Nonetheless, because there are no current proposals for other wind projects in the area;
such future development is considered too speculative at this time.
Comment: I am concerned that the DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. [LTR 266, CMT 2]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: The DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. [LTR 267, CMT 3]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: I would add that coordination with the general public seems deficient, and this critical purpose of NEPA has thereby fallen short. Thank you for extending the public comment period and allowing me to submit these comments into the record. [LTR 267, CMT 3]

Response: BPA and EFSEC initially allowed a 45-day public review and comment period for the Draft EIS, which is consistent with NEPA and SEPA regulations for allowing adequate time for DEIS review and comment. In order to further facilitate public involvement however, the lead agencies agreed to extend the end of the original comment period (July 19, 2010) for an additional 39 days (to August 27, 2010), thereby allowing a total of 91 days for public review and comment on the DEIS. The lead agencies provided timely and broad distribution of the DEIS, wide noticing, web postings, and periodic updates to ensure sufficient public awareness of the DEIS and comment period. The lead agencies also posted the DEIS on the agencies’ websites and held public meetings on the DEIS to ensure that the public was provided with opportunities for involvement.

Comment: This proposed project does not appear to have been adequately coordinated with the Yakima Indian tribes, and thereby places Native cultural resources at risk. [LTR 267, CMT 3]

Response: As described in both Section 1.0 and Section 3.10 of the EIS, the lead agencies along with the Applicant have coordinated with the Confederated Tribes and Bands of the
Yakama Nation (including the Yakama Nation Cultural Resources Department) concerning the proposed Project. The Applicant also coordinated with two local resident tribal members to assist with the identification of potential sensitive, traditional, and/or sacred resources. In addition, BPA undertook consultation with the Yakama Nation through the NHPA Section 106 process to address effects of BPA’s interconnection activities. While no resources of significance to the Tribe were identified within the APE of proposed interconnection, the Tribe provided information indicating that the Chemawa Hill area was culturally sensitive. Although the available information about the area was somewhat conflicting, the Applicant agreed to limit the number of turbines in that area in part to address the Tribe’s concerns. In addition, the Applicant committed to continue to work with the Tribe to address siting of towers and other construction disturbances to address tribal cultural resource concerns where practicable to do so while maintaining the viability of the project.

Comment: I am concerned that the DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. The DEIS has other flaws. [LTR 270, CMT 2]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: I am concerned that the DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. The DEIS has other flaws. [LTR 274, CMT 2]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: The alternatives considered (briefly?) but eliminated from detailed study were given short shrift. [LTR 276, CMT 1]

Response: Consistent with both SEPA and NEPA requirements, alternatives considered but eliminated from detailed study in the EIS are briefly discussed, and this discussion identifies the reasons why these alternatives were eliminated from further study. The lead agencies believe that these alternatives thus were sufficiently addressed. As discussed in other responses to
comments, additional information has been provided concerning alternative locations to further clarify this information.

Comment: The design of the proposed facility is fatally flawed for lack of statutorily required alternatives and insufficient mitigation analysis. [LTR 283, CMT 13]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: Is the proponent’s staunch resistance to alternative designs related to a minimum output required for just such a sale? [LTR 283, CMT 18]

Response: Please see response to Comment LTR 61, CMT 1 above.

Comment: I am concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. [LTR 287, CMT 3]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: I am also concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. [LTR 288, CMT 3]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: I am concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate. The DEIS has other flaws. [LTR 289, CMT 3]
Response: Please see response to Comment LTR 66, CMT 1 above.

This is inadequate. [LTR 309, CMT 3]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: Please define counterpoise and staging areas. [LTR 311, CMT 6]

Response: Staging areas are temporary areas used assist in the installation of Project components during Project construction. These areas are used to prepare and store Project components and equipment as needed. Previously disturbed areas are used where possible, and any additional disturbance is restored and re-vegetated after construction. Counterpoise is wire connected to Project components that is installed underground to help dissipate any lightning strikes. Counterpoise typically consists of 3/8-inch diameter wire buried about 12 to 18 inches underground. Small trenches are dug for installation, with the disturbed area restored and re-vegetated after installation.

Comment: Why aren’t all these “components” addressed by BPA in the Whistling Ridge DEIS? Towers, Conductors, Counterpoise, Fiber Optic Cable, Right-of-Way Clearing, Access Roads, Staging Areas, Gates, Substation Facilities. [LTR 311, CMT 7]

Response: To the extent any of these components are proposed as part of the proposed Project, they are included and addressed in the EIS.

Comment: So, why doesn’t the Whistling Ridge DEIS have a BPA analysis about the impacts of not building any new transmission lines, or using the old transmission line, or substations? Further, the I-5 EIS goes on to say that it “...will evaluate direct, indirect and cumulative impacts to: Land Use, Cultural Resources, Aesthetics, Sensitive Plants and Animals and their Habitats, Fish and Water Resources, Erosion and Soils, Socioeconomics and Public Services, Electric and Magnetic Fields, Noise, Public Health and Safety, Air Quality, Recreation, Environmental Justice.” From the Whistling Ridge DEIS, it is very apparent that BPA did not address any of these issues as they pertain to transmission lines and substations, technology that BPA should know something about! [LTR 311, CMT 9]
Response: The EIS for the proposed Project addresses both the direct and indirect impacts of the proposed Project itself, as well as the cumulative effect of the proposed Project in combination with other past, present, and reasonably foreseeable future projects. Since the scope of the proposed action is the wind Project and its proposed interconnection to the FCRTS, that is the focus of the analysis of direct and indirect impacts in the EIS. Other existing and proposed BPA transmission lines and other facilities in the general vicinity of the proposed Project were considered in the cumulative impact analysis (Section 3.14) of the EIS. This section has been revised to more clearly reflect that these facilities were considered in this analysis.

Comment: Why isn’t the “No Action Alternative” addressed more fully and thoughtfully in the DEIS? [LTR 311, CMT 9]

Response: In preparing the EIS, the lead agencies gave substantial treatment to the No Action alternative, commensurate with its potential level of impacts. Since the No Action alternative would involve the Project being denied by EFSEC and/or BPA (and thus not being built), inherently there is less to describe and analyze about this alternative. Nonetheless, this alternative is fully described in Chapter 2 of the EIS, and fully analyzed in Chapter 3 of the EIS.

Comment: One of the requirements of these environmental impact statements is that alternatives are presented. And while I didn’t see much in alternatives, SDS, Whistling Ridge owns about 80,000 acres in the state of Washington, and they choose these few acres. Why can’t they locate the project elsewhere so it won’t impact the National Scenic Area, peoples backyards and tourism? [LTR 317, CMT 33]

Response: Please see response to Comment LTR 79, CMT 2 above.

Comment: The applicant insists on 70-MW, why? What are the alternatives? If there are no alternatives we need to know why. [LTR 317, CMT 34]

Response: Please see response to Comment LTR 61, CMT 1 above.

Comment: Whistling Ridge Energy Project will need to proceed as an integrated whole. You cannot remove pieces of the project and hope for its success. [LTR 317, CMT 39]

Response: Please see response to Comment LTR 61, CMT 1 above.
Comment: We strongly recommend removing Turbine Corridors A-1 though A-7 from further project consideration. Visual impacts will seriously degrade core scenic and historic landscape values. [LTR 317, CMT 59]

Response: Please see response to Comment LTR 79, CMT 1 above.

Comment: Consider reasonable alternatives and look at the language from these federal agencies who are mandated to protect this area. [LTR 317, CMT 63]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: The only alternative discussed is no action, so technically they are no alternative. [LTR 317, CMT 85]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: The alternatives addressed are insufficient. It is said we need 70-MW or we cannot do the project, and there is no place else to do it and we have absolute every array that we’ve proposed. This is disingenuous to the process of SEPA to allow that to stand. I think there needs to be a hard look at the 70,000+ acres owned to come up with some viable alternatives to compare this to. [LTR 318, CMT 15]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: The EIS does not have an appropriate list of alternatives. It states only one action item and mentions throughout the document that it is one of the alternatives. How can the proposed action also be an alternative? The only alternative stated is the no-action alternative. [LTR 318, CMT 33]

Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: NEPA and SEPA require two major points with respect to alternatives. 1) there be a reasonable range of alternatives considered and 2) each reasonable alternative be rigorously explored and objectively evaluated. In this project we have two alternative: the project and no action. This is not in accordance with NEPA/SEPA requirements. [LTR 318, CMT 45]
Response: Please see response to Comment LTR 66, CMT 1 above.

Comment: Please consider Hood River in your impact analysis. [LTR 318, CMT 51]

Response: The community of Hood River was considered in the analysis of several environmental impact topics including land use, transportation, socioeconomic, and visual impacts.

Comment: The authors of the EIS should consider the reconfiguration of the project that was rejected. [LTR 318, CMT 58]

Response: Please see response to Comment LTR 79, CMT 1 above.

G.3 AFFECTED ENVIRONMENT, IMPACTS AND MITIGATION

G.3.1 EARTH

Comment: The project would require substantial soil relocation. Spoils sites should therefore be approved by a qualified specialist and their locations identified in the EIS draft. [LTR 79, CMT 10]

Response: As discussed in Section 3.1.3, a Stormwater Pollution Prevention Plan (SWPPP), an Erosion and Sedimentation Control Plan, and an Environmental Protection Control Plan will be submitted to EFSEC for approval. These plans will include BMPs to minimize erosion and runoff from areas such as spoils piles. EFSEC may require the Applicant to obtain coverage under Ecology's Construction Stormwater General Permit since it would disturb more than 1 acre of land. Placement of all spoils piles would be regulated by the conditions of this permit. At this time, the location of the spoils piles is not known because the final location of the wind turbines has not been completed.

Comment: [In reference to soil contamination] - The discussion regarding soils does not address possible presence of contaminants along the access road right of way or at the project site. The FEIS should include the results of a Phase I Environmental Site Assessment to determine if and where contaminated soils may exist. [LTR 177, CMT 26]
Response: There are no past land use activities that would lead the Applicant to believe hazardous materials or contaminants are present along the access roads or within the Project Area. Additionally, no contaminants were found during recent access road improvements within the Project Area. Therefore, the Applicant will not conduct a Phase I Environmental Site Assessment. However, the construction management plan would include provisions to ensure worker safety as discussed in Section 4.2 and required by state and federal laws.

Comment: [In reference to DEIS Section 3.1.2.1] Landslide evaluation...without danger....to surrounding environment. No obvious recent mass wasting features were observed in the aerial photos or during sight reconnaissance. Class III LHAs were delineated adjacent to proposed wind turbines along the southern Tower Line A and along Tower Line C. Fails to show detailed topography, detailed topographical changes, and how it affects landslide danger. Attempts to depict turbines outside of slide area, but common knowledge dictates the pad and activities will be in the unstable slopes. [LTR 178, CMT 75]

Response: As discussed in Section 2.1.2 and in other responses, final siting of the wind turbines and associated facilities would be done following completion of the EFSEC Site Certificate and a detailed geotechnical investigation. As part of the final siting process, grading/excavation plans would be developed.

Comment: [In reference to DEIS Section 3.1.2.1], the changes to topography would be minor to moderate depending on location "Changes in topography" denotes significant earth moving. Need detailed maps and grading/excavating plans to able to assess the extent of the topographical changes. Remedy - The extent of topographical changes should be identified in the DEIS test, as well as the photomontages. [LTR 178, CMT 74]

Response: Please see response to Comment LTR 178, CMT 75 above.

Comment: [In reference to] Section 3.1.2.1, [the] entire section, [n]o information is given as to how cite decommissioning will occur so impacts cannot be assessed. [LTR 178, CMT 79]

Response: Section 2.1.7 of the EIS includes information concerning potential future decommissioning and site restoration that is reasonably foreseeable at this time. Given that these activities would occur 30 or more years into the future, it is not currently known what types of technologies or techniques would be available at that time to best accomplish decommissioning and site restoration. Any specific plan developed at this time thus would be not only speculative, but also could be viewed as limiting these activities to only currently available technologies and techniques. As discussed further in Section 2.1.7, any future decommissioning and site restoration would be conducted in accordance with applicable state laws, which would include an assessment of potential impacts from these activities. To the extent that EFSEC has authority
over possible actions taken to “re-power” the Project in the future, these actions also would be subject to appropriate environmental review.

---

**Comment:** [In reference to DEIS Section 3.1.2.1], the primary impacts during construction would be potential for erosion, landslides, soil compaction and changes to topography. Where these impacts will occur needs to be disclosed fully, particularly where changes to topography will occur. Remedy - Provide a supplemental DEIS that fully discloses where the topographical changes will occur and provide before and after contour maps for all locations. [LTR 178, CMT 131]

**Response:** Please see response to Comment LTR 178, CMT 75 above.

---

**Comment:** [The Volcanic Activity] section should discuss how ash from a volcanic eruption may impact the operation of wind turbines, transmission lines, and other elements of the project. [LTR 177, CMT 27]

**Response:** The potential for ash fall was discussed in DEIS Section 3.1.2.1. Ash fall would be a potential unavoidable impact resulting from a volcanic eruption and there are currently no mitigation options available for this type of geological event.

---

**Comment:** Why is volcanic ash deposition of such concern that it is mentioned here? Granted, several of the soils present do contain a volcanic ash component, but it is not clear to me why this appears, since there is no control over the possible event and, depending on the severity of an ash fall, no mitigation measures would be possible. Large amounts of ash could be physically removed, but would that be mitigation? [LTR 272, CMT 9]

**Response:** Volcanic ash deposition is discussed as a possible geologic hazard within the Project Area. The commenter is correct in stating that there would be no mitigation measures that could be implemented to reduce ash deposition.

---

**Comment:** Does the statement regarding mass wasting “no obvious recent mass wasting features" imply that there is evidence of the phenomena having occurred on the site in the not-so-recent past? If so, then this is another reason why a more thorough geologic assessment be conducted, before the project is evaluated by the Council. Although the soil type present on part of the project site has low liquefaction potential, massive excavation and refill, as in the 8.5 mile trench, may disturb soil structure enough to render the possibility greater than in the undisturbed state. Although liquefaction of soils is generally associated with earthquake activity, a similar phenomenon may result when soils become oversaturated. [LTR 272, CMT 9]
Response: As discussed in Section 2.1.2 and in other responses, a detailed geotechnical investigation of the specific locations of all wind project elements would be conducted. If this investigation indicates the potential for slope instability at turbine sites or other Project facilities such as access roads, these facilities will be redesigned or relocated to avoid this risk.

Comment: The [DEIS] shows that the soils on the proposed Whistling Ridge wind farm site, 1152 acres located in Sections 5, 6, 7, 8, and 18 of T3N, R10E, and on Section 13 of T3N, R9E, are unstable and should not be disturbed through the building of this project, a project that would involve thousands of tons of ground movement and disturbance, with the addition of thousands of tons of concrete and wind turbines on top of this unstable soil. [LTR 281, CMT 1]

Response: As discussed in Section 3.1.2.1, the landslide evaluation concluded that the Project could be constructed without danger to human life or the surrounding environment due to landslide hazard. Further subsurface investigation in support of final tower foundation design would help determine if there are weak rock or soil layers that could contribute to more deep-seated failure of the ridges and provide information on the quality of the rock underlying the ridgelines.

Comment: Geologic and soils information is troubling for anyone the proposed project site which is pretty steep, and this project proposes to disturb a great deal of that. Blasting would disturb fragile habitats. The soil types present are unstable. [LTR 318, CMT 41]

Response: Please see response to Comment LTR 281, CMT 1 above.

Comment: In reading the DEIS, it also came to my attention that the soil descriptions used by the proponent were not as complete and not as informative as the soil descriptions in the Soil Survey of Skamania County, Washington, done by the U.S. Department of Agriculture, Soil Conservation Service, dated October 1990. It is as if certain, very pertinent information was left out of the DEIS. I have attempted to put this information in this memo. [LTR 281, CMT 2]

Response: Information regarding soil series relevant to the proposed Project was included in Section 3.1.1.3.

Comment: The soils on the proposed wind farm site can be found in the U.S. Department of Agriculture’s Soil Conservation Service’s Soil Survey of Skamania County Area, Washington, October 1990. The DEIS descriptions are in ITALICS; other descriptions and information for each soil type is from the Soil Survey book (I have copied freely!). The soil types are numbered, as follows: #66, McElroy Series (included in this unit are small areas of Chemawa, Timberhead, Underwood, and Undusk soils) gravelly loam, 5 – 15 percent slopes. “The McElroy series
consists of very deep soils (up to 5 feet) formed in colluvium and residuum from basalt with a mantle of volcanic ash that influences soils in the top 9 to 13 inches. The soils exist on the footslopes and backslopes of mountains on slopes from 5 to 90 percent at elevations from 400 to 2,600 feet in eastern Skamania County and western Klickitat County. McElroy Soils are well drained with medium to rapid runoff and moderate permeability. The series was established in 1981 following the introduction of volcanic ash from the eruption of Mt. St. Helens.” The average annual precipitation is 55 inches, average air temperature is about 46 degrees Fahrenheit (F), and the average frost-free period is 105 – 125 days. Hazard of water erosion is moderate. This unit is used for woodland, hayland, pastureland, homesites, wildlife habitat, and recreation. Douglas fir, ponderosa pine, and grand fir are the main woodland species. Oregon white oak and bigleaf maple are trees of limited extent in this soil unit. Main limitation for harvesting timber is seasonal soil wetness...wheeled and tracked equipment produces ruts, compacts the soil, and damages the roots of trees...Unsurfaced roads and skid trails are soft and slippery and can be impassable when wet...Occasional snowpack hinders the use of equipment and limits access in winter. This unit is well suited to use as hayland and pastureland. The main limitation of this unit for use as homesites is the steepness of slope. Erosion is a hazard in the steeper areas. Capability sub-class IIIe. [LTR 281, CMT 7]

Response: Please see response to Comment LTR 281, CMT 2 above.

Comment: #67, McElroy Series (included in this unit are small areas of Chemawa, Timberhead, Underwood, and Undusk soils), gravelly loam, 15 to 30 percent slopes. It formed in colluvium derived dominantly from basalt with a mantle of volcanic ash. The native vegetation is mixed conifers and shrubs. Elevation is from 400 to 2300 feet. [Note: the DEIS states that the McElroy Series is from 400 to 2600.] The average annual precipitation is 55 inches, average air temperature is about 46 degrees F, and the average frost-free period is 105 – 125 days. Runoff is medium and the hazard of water erosion is moderate. Most areas of this unit are used for woodland, pastureland, hayland, wildlife habitat, recreation, and watershed. A few areas are used as homesites. Douglas fir, ponderosa pine, and grand fir are the main woodland species on this unit. Limited extent trees are Oregon white oak and bigleaf maple. Main limitation for harvesting timber is seasonal soil wetness...wheeled and tracked equipment produces ruts, compacts the soil, and damages the roots of trees...Unsurfaced roads and skid trails are soft and slippery and can be impassable when wet...Occasional snowpack hinders the use of equipment and limits access in winter. This unit is well suited to use as hayland and pastureland. The main limitations are steepness of slope and the hazard of erosion. Main limitation for use as homesites is the steepness of slope and erosion. Restricted permeability and steepness of slope increase the possibility of failure of septic tank absorption fields. Access roads should be designed to provide adequate cut-slope grade, and drains are needed to control surface runoff and keep soil losses to a minimum. Capability subclass IVe. [LTR 281, CMT 8]

Response: Please see response to Comment LTR 281, CMT 2 above.
Comment:  #68, McElroy Series (included in this unit are small areas of Chemawa, Timberhead, Underwood, and Undusk soils), gravelly loam, 30 – 65 percent slopes. Very deep, well-drained soil is on the back slopes of mountains. It formed in colluvium derived dominantly from basalt with a mantle of volcanic ash. The native vegetation is mainly mixed conifers and shrubs. Elevation is 400 to 2300 feet. The average annual precipitation is 55 inches, average air temperature is about 46 degrees F, and the average frost-free period is 105 – 125 days. Runoff is rapid, and the hazard of water erosion is severe. This unit is used for woodland, wildlife habitat, recreation, and watershed. Douglas fir, ponderosa pine, and grand fir are the main woodland species on this unit. Oregon white oak and bigleaf maple are limited extent trees on the unit. Steep slopes restrict the use of wheeled and tracked equipment in skidding. Use of wheeled and tracked equipment when the soil is moist produces ruts, compacts the soil, and damages the roots of trees. Logging roads require suitable surfacing for year-round use. Occasional snowpack hinders the use of equipment and limits access in winter. Steep yarding paths, skid trails, and firebreaks are subject to rilling and gullying unless plant cover is maintained or adequate water bars are provided. Capability sub-class VIe. [LTR 281, CMT 10]

Response:  Please see response to Comment LTR 281, CMT 2 above.

Comment:  #135, Timberhead Series, gravelly loam, 5 to 30 percent slopes. The Timberhead series consists of very deep soils (up to 5 feet) formed in residuum and colluvium from basalt mixed with volcanic ash. The soils exist on mountain ridges between 5 and 30 percent at elevations from 2,000 to 3,600 feet in Skamania County and western Klickitat County. Timberhead Series soils are well drained with medium to rapid runoff and moderately high to high permeability. [Note: The Soil Survey book states that this unit is at 2000 to 2800 feet elevation.] Average annual precipitation is about 60 inches, the average annual air temp is 44 degrees F, and the average frost-free period is 95 to 115 days. Included in this unit are small areas of McElroy, Underwood, and Undusk soils. Runoff is medium, and the hazard of water erosion is moderate. Most areas of this unit are used for woodland, recreation, wildlife habitat, and watershed. A few areas are used as grazeable woodland. Douglas fir, grand fir, and western hemlock are the main woodland species on this unit. [Would there be bats here, just like at the canopy crane, because of the hemlock?] Among the trees of limited extent is western redcedar. Areas on ridge tops that are subject to strong, persistent winds [how strong and how persistent?] are less productive than other areas of this unit. The main limitation of harvesting timber is seasonal soil wetness. Use of wheeled and tracked equipment when the soil is moist produces ruts, compacts the soil, and damages the roots of trees. Unsurfaced roads and skid trails are soft and slippery and can be impassable when wet. Occasional snowpack hinder the use of equipment and limits access in winter. This map unit is in capability subclass IVe. [LTR 281, CMT 11]

Response:  Please see response to Comment LTR 281, CMT 2 above.

Comment:  #136, Timberhead Series, gravelly loam, 30 to 65 percent slopes. The Timberhead series consists of very deep soils (up to 5 feet) formed in residuum and colluvium
from basalt mixed with volcanic ash. The soils exist on mountain ridges between 5 and 30 percent at elevations from 2,000 to 3,600 feet in Skamania County and western Klickitat County. Timberhead Series soils are well drained with medium to rapid runoff and moderately high to high permeability. [Note: the Soil Survey book states that this soil unit is in the 2000 to 2800 foot elevation range.] Average annual precipitation is about 60 inches, the average annual air temp is 44 degrees F, and the average frost-free period is 95 to 115 days. Included in this unit are small areas of McElroy, Underwood, and Undusk soils. Also included are small areas of Rock outcrop and moderately deep soils over basalt. Available water capacity is moderately high. The hazard of water erosion is severe. Most areas of this unit are used for woodland, recreation, wildlife habitat, and watershed. Douglas fir, grand fir, and western hemlock are the main woodland species on this unit. Western redcedar is a tree of limited extent. The main limitation for harvesting timber is steepness of slope, which restricts the use of wheeled and tracked equipment. Use of wheeled and tracked equipment when the soil is moist produces ruts, compacts the soil, and damages the roots of trees. Occasional snowpack hinders the use of equipment and limits access in winter. Steep yarding paths, skid trails, and firebreaks, are subject to rilling and gullyling unless plant cover is maintained or adequate water bars are provided. Capability subclass VIIe. [LTR 281, CMT 12]

Response: Please see response to Comment LTR 281, CMT 2 above.

Comment: #144, Underwood loam, 2 to 15 percent slopes. The Underwood series consists of very deep soils (5 feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between 2 and 50 percent at elevations between 500 and 2,700 feet in southeast Skamania County and west Klickitat County. Underwood Series soils are well drained with slow to medium runoff and moderately high permeability. [Note: The Soil Survey book states that this unit is at 500 to 2000 feet elevation.] The native vegetation is mainly mixed conifers and shrubs. The average annual precipitation is about 50 inches, the average annual air temperature is about 46 degrees F, and the average frost-free period is 100 to 150 days. Included in this unit are small areas of Chemawa and McElroy soils on terraces and foot slopes and Timberhead and Undusk soils on ridgetops. Also included are small areas of soils that are more than 35 percent clay. Included areas make up about 10 percent of the total acreage. Permeability of this Underwood soil is moderately slow. Available water capacity is high. Runoff is medium, and the hazard of water erosion is moderate. This unit is used for woodland, hayland, pastureland, orchards, homesites, wildlife habitat, and recreation. Douglas fir, ponderosa pine, and grand fir are the main woodland species on this unit. Among the trees of limited extent are Oregon white oak and bigleaf maple. The main limitation for harvesting timber is seasonal soil wetness. Use of wheeled and tracked equipment when the soil is moist produces ruts, compacts the soil, and damages the roots of trees. Unsurfaced roads and skid trails are soft and can be impassable when wet. Logging roads require suitable surfacing for year-round use. Occasional snowpack hinders the use of equipment and limits access in winter. The main limitations of this unit for use as homesites are steepness of slope, shrink-swell potential, moderately slow permeability, and the hazard of erosion in the steeper areas. Use of sandy backfill for the trench and long absorption lines helps to compensate for the moderately slow permeability of the soil. During the rainy season, effluent from onsite sewage disposal
systems may seep at points downslope. If the density of housing is moderate to high, community sewage systems are needed to prevent contamination of water supplies as a result of seepage from onsite disposal systems. The effects of shrinking and swelling can be minimized by using proper engineering designs. Buildings and roads should be designed to offset the limited ability of the soil in this unit to support a load. This map unit is in capability subclass Ille. [LTR 281, CMT 13]

Response: Please see response to Comment LTR 281, CMT 2 above.

Comment: #147, Undusk gravelly loam, 5 to 30 percent slopes. The Undusk series consists of very deep soils (5 feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between 5 and 65 percent at elevations between 2,000 and 2,800 feet in southeast Skamania County and west Klickitat County. Undusk Series soils are well drained with slow to medium runoff and moderately high permeability. Based on the current test pits and field observations, the site soil is best represented as Soil Site Class D (stiff soils). Rock with varying strength and weathering characteristics was encountered at depths ranging from 3 to 12 feet bgs. The average annual precipitation is about 55 inches, the average annual air temperature is about 44 degrees F, and the average frost-free period is 90 to 120 days. The subsoil to a depth of 60 inches or more is dark brown very gravelly loam and extremely gravelly loam. Included in this unit are small areas of Chemawa, McElroy, Timberhead, and Underwood soils on ridges and back slopes and St. Martin soils on landslides. Also included are small areas of soils that are less than 35 percent rock fragments and soils that are shallow to bedrock. Included areas make up about 12 percent of the total acreage. Permeability of this Undusk soil is moderate. Available water capacity is moderately high. Runoff is medium, and the hazard of water erosion is moderate. This unit is used for woodland, wildlife habitat, recreation, and watershed. Douglas fir, grand fir, and western hemlock are the main woodland species on this unit. Among the trees of limited extent are red alder and western red cedar. Areas on ridge tops that are subject to strong, persistent winds are less productive than other areas of this unit. The main limitation for harvesting timber is seasonal soil wetness. Use of wheeled and tracked equipment when the soil is moist produces ruts, compacts the soil, and damages the roots of trees. Unsurfaced roads and skid trails are soft and can be impassable when wet. Logging roads require suitable surfacing for year-round use. Occasional snowpack hinders the use of equipment and limits access in winter. Logging activities can readily displace the surface layer. This map unit is in capability subclass IVe. [LTR 281, CMT 14]

Response: Please see response to Comment LTR 281, CMT 2 above.

Comment: #177, Undefined Soil Unit located west of wind turbine string C1-C4? These units sit next to the turbine strings? [LTR 281, CMT 15]

Response: All soil series found within the Project Area are shown on Figure 3.1-3, including those located west of the “C” turbine string.
Comment: Turbines are heavy, unwieldy machines. In my research, I came across the following information, several articles—one from Wind Watch, one from aweo.org, and one on transporting wind turbines—which provide insight on just how big and weighty wind turbines actually are, and I believe this information is very pertinent to the evaluation of weight effects on the soils located in the proposed area of the Whistling Ridge wind farm. [LTR 281, CMT 16]

Response: Comment acknowledged.

Comment: [In reference to Section 3.1.2.1 Proposed Action; PDF pg. 11], the initial site restoration plan and the decommissioning plan SHOULD be part of the DEIS and SHOULD also be included in the FEIS. We should all be able to evaluate all of SDS’s and the BPA’s plans for this proposal, NOW not later, especially if “the initial site restoration plan will…identify, evaluate, and resolve all major environmental and public health and safety issues...including potential changes to soils, topography, or erosion...impacts to earth...mitigation measure...”. All of these issues should be addressed in the DEIS and these plans should be available for public comment and input NOW. [LTR 286, CMT 8]

Response: Section 2.1.7 of the EIS includes information concerning potential future decommissioning and site restoration that is reasonably foreseeable at this time. Given that these activities would occur 30 or more years into the future, it is not currently known what types of technologies or techniques would be available at that time to best accomplish decommissioning and site restoration. Any specific plan developed at this time thus would be not only speculative, but also could be viewed as limiting these activities to only currently available technologies and techniques. As discussed in Section 2.1.7, any future decommissioning and site restoration would be conducted in accordance with applicable state laws, which would include an assessment of potential impacts from these activities. To the extent that EFSEC has authority over possible actions taken to “re-power” the Project in the future, these actions also would be subject to appropriate environmental review.

Comment: Regarding soil stability - Skamania County has failed to comply with the critical areas ordinance that has been mandated by the state upon this county, and it delayed that process. Therefore it is possible that particular areas of concern are not mentioned because they have not been legislatively acted on at a local basis. [LTR 318, CMT 13]

Response: As discussed in Section 4.10, EFSEC will specify the conditions of construction and operation of the proposed project. This provision operates to supersede all state and local land use permitting related to energy facility sites that are under EFSEC’s jurisdiction. However, a determination of consistency with local land use regulation is required. Skamania County has provided EFSEC with a letter and Resolution 2009-54 stating that proposed Project would comply with the land use policies and zoning regulations for the vicinity of the proposed Project. Furthermore, EFSEC believes that Section 3.1.1.4 in the DEIS, and the referenced geotechnical report (URS 2009), adequately analyzed the issue of soil stability in and near the Project Area. As discussed in Section 2.1.2 and in other responses, a detailed geotechnical
investigation of the specific locations of all wind project elements would be conducted prior to construction. If this investigation indicates the potential for slope instability at turbine sites or other Project facilities such as access roads, these facilities will be redesigned or relocated to avoid this risk.

Comment: There is a DNR FPA application that indicates the A-7 through 7 portion of the eastern slope is - unstable slopes, high erosion potential, and a high mass wasting potential, and there is a portion of the slope that is intentionally not logged due to concerns about stability. [LTR 318, CMT 14]

Response: For a discussion of unstable slopes and mass wasting potential, please refer to Section 3.1.3, Mitigation Measures. The following mitigation measures were identified to avoid, minimize, and compensate for potential impacts of the proposed Project related to geology, soils, topography, and geologic hazards.

Comment: In Section 3.1.1.4, Geologic Hazards, this section should be expanded to address geologic hazard issues related to the proposed access road (West Pit Road). That this road traverses lands identified as Class II Landslide Hazards is of particular concern. See Table 3.1-4.8 [Footnote 8: Table 3.1-4 should be revised so that the locations of the proposed access road, as well as other access road alternatives, are easily discernable.] The DEIS should also be revised to include a discussion regarding the extent to which Skamania County has assessed whether the project site or the area traversed by the proposed access road contains Class I landslide hazards (Severe).9 [Footnote 9: To qualify as a Class I landslide hazard, the location must be designated as such by the local legislative body, in this case Skamania County. See DEIS at § 3.1.1.4 Landslides.] If such an assessment has not been done, the discussion regarding landslide hazards should be expanded to determine whether there are affected areas that would otherwise meet the criteria for a Class I landslide hazards, even though they have not been formally designated as such by the County. [LTR 177, CMT 24]

Response: As discussed in Section 2.1.2, final siting of the wind turbines and associated facilities would be done following completion of the EFSEC Site Certificate. Prior to this final siting process, as a condition of the Site Certificate and as discussed in Section 3.1.3, a detailed geotechnical investigation of the specific locations of all wind project elements would be conducted. If this investigation indicates the potential for slope instability at turbine sites or other project facilities such as access roads (including improvements to West Pit Road), these facilities will be redesigned or relocated to avoid this risk. As discussed in Section 2.1.3.7, all road improvements required for the proposed Project would be designed and constructed under the direction of a licensed engineer, in accordance with the Skamania County Private Road Guidelines and Development Assistance Manual. All county roads requiring improvements would be designed and constructed in accordance with the WSDOT Design Manual.
Comment: [In DEIS Section 3.1.2.1, Proposed Actions - Access Road], this section should be expanded to include a discussion of geologic hazards and their impact on the access road during both the construction and operation of the proposed project, including the environmental impacts that may arise from locating the access road in a Class II landslide area. [LTR 177, CMT 25]

Response: Please see response to Comment LTR 177, CMT 24 above.

Comment: [DEIS Section 3.1.1.2, Regional Geology, of the DEIS] states “Regional geologic maps indicate the presence of Quaternary-age mass wasting landslide deposits located north of Underwood Mountain (Figure 3.1-2). These deposits are mapped as a large landslide, estimated to be approximately 1/3 square mile in area and almost a mile long. However, based on field work conducted in 2007, there is no obvious evidence to suggest the presence of a landslide as mapped on the 1:100,000 scale geologic map. If landslide deposits are present, they have been exposed long enough that most or all of the geomorphic evidence has been removed by erosion.” (p. 3-3) This is not an acceptable analysis. See Reference A, at the end of this document [see letter 177 in Appendix H] for more information on mass wasting but, briefly, “Mass wasting, the downhill movement of soil and rock under the influence of gravity, encompasses a variety of physical processes by which mountain ranges are eroded. These processes include: Creep - slow, nearly continuous downslope movement that is induced by either freeze/thaw cycles or wet/dry cycles. Slides - sudden downhill movement of masses of rock or sediment. Debris flows- dense, fluid mixtures of rock, sand, mud, and water. There are other categories of mass wasting processes such as slumps, rock flows, rockfalls, block glides (etc...) that can be grouped together or separately with creep, slides, and debris flows depending on which characteristics that share in common. All of these processes share one thing in common, namely, that they are caused by the incessant downward pull of gravity, which moves loose slope material downwards.” [LTR 281, CMT 3]

Response: Please see response to Comment LTR 177, CMT 24 above.

Comment: “These deposits are mapped as a large landslide, estimated to be approximately 1/3 square mile in area and almost a mile long. However, based on field work conducted in 2007, there is no obvious evidence to suggest the presence of a landslide as mapped on the 1:100,000 scale geologic map. If landslide deposits are present, they have been exposed long enough that most or all of the geomorphic evidence has been removed by erosion.” “No obvious evidence...If landslide deposits are present...they have been exposed long enough that most or all of the geomorphic evidence has been removed...”!!! These are astonishing statements, made without any type of real, geological evidence, i.e., a sub-surface hazard survey, drill holes, etc., in the DEIS. An in-depth geological study should be made of the entire proposed site—before the project is approved, not after. Geomorphic evidence of landslides does not just disappear—a near-surface hazard survey is a tool to find out just what is going on under the exposed, eroded surface. This has not, apparently, been done for this DEIS, and it should be. This proposed
wind farm would be situated on top of a unstable ridge line, subject to mass wasting. [LTR 281, CMT 4]

Response: Please see response to Comment LTR 177, CMT 24 above.

Comment: [DEIS Section 3.1.1.4, Geologic Hazards, Earthquakes states that] earthquakes are the result of sudden releases of built-up stress within the tectonic plates that make up the earth’s surface. Stress accumulates where movement between plates or on faults produces friction. No faults are mapped within the footprint of the proposed project area. However, faults are mapped approximately 1.5 miles to the southwest and northeast. (Pezzopane 1993 and Geomatrix 1995) Many of these faults are inferred, and shown as dotted lines buried by younger surficial deposits. While the activity of the area faults is unknown, a review of aerial photography showed no indication of recent movement along the trace of the inferred faults. There have been no surface-rupture earthquakes on any fault within northwestern Oregon or southwestern Washington in historic times, and investigations of the regional faults have been limited. According to the updated National Seismic Hazard Maps published by the US Geological Survey (USGS) in 2008 (Petersen et al. 2008 and USGS 2009), the peak ground acceleration estimated for the area of the Whistling Ridge site is 0.18g for a 475-year return period earthquake (i.e., ground motion with a 10 percent chance of being exceeded in 50 years) and 0.40g for a 2,475 year return period earthquake (i.e., ground motion with a 2 percent chance of being exceeded in 50 years). Large earthquakes at more distant faults could cause prolonged ground movement at the project site. Information on historic large earthquakes can be found in the Application for Site Certification Section 3.1 (Appendix A). [LTR 281, CMT 5]

Response: Please see response to Comment LTR 177, CMT 24 above.

Comment: [Additionally, DEIS Section 3.1.1.4, Geologic Hazards, Landslides states that] the landslide evaluation conducted for the Application for Site Certification concluded that the project could be constructed and operated without danger to human life or the surrounding environment due to landslide hazards. Although none of the proposed turbines are located within Class II LHAs, several of the towers along the western side of the project site (Tower Lines A and B) are located along ridgelines with descending slopes that are locally greater than 35 degrees (70 percent). Based on studies conducted for the Application for Site Certification, it appears that the primary concern for towers located adjacent to the Class II LHAs is the potential for headward erosion of the steep drainages by debris or earth flow processes. Erosion rates of these drainages are unknown, but no obvious recent mass wasting features were observed in the aerial photos or during the site reconnaissance. Further subsurface investigation in support of final tower foundation design would help determine if there are weak rock or soil layers that could contribute to more deep-seated failure of the ridges and provide information on the quality of the rock underlying the ridgelines. [LTR 281, CMT 6]

Response: Please see response to Comment LTR 177, CMT 24 above.
Comment: An in-depth geological study should be made of the entire proposed site—before the project is approved, not after. A near-surface seismic hazard survey and deep coring should be required before this project is approved. [LTR 281, CMT 17]

Response: Please see response to Comment LTR 177, CMT 24 above.

Comment: The impacts of the turbines’ weights on the mountain ridges in the DEIS has not been fully addressed. Could mass wasting result from ridges being flattened, heavy machinery being installed, deep anchors disturbing the soils, etc? [LTR 281, CMT 19]

Response: Please see response to Comment LTR 177, CMT 24 above.

Comment: There are a lot of questions about the geology of the proposal area that have not been adequately answered in the DEIS. We need complete data in order to properly evaluate the DEIS. [LTR 281, CMT 24]

Response: Please see response to Comment LTR 177, CMT 24 above.

Comment: [In reference to DEIS Section 3.1.1.2, Regional Geography] - Just because there is "no obvious evidence to suggest the presence of landslides" does not mean that the landslide does not exist or that mass wasting is not a definite possibility. What is mass wasting? A Wisconsin geology class syllabus defines mass wasting as follows: "Mass-wasting processes: Mass-wasting processes such as creep, landslides, and debris flows are distinguished from each other in part by whether they occur rapidly or slowly. Landslides are capable of transporting massive amounts of rock and soil downslope or miles in very short periods (e.g. minutes). Creep can also transport much material, but at rates of only millimeters per year. Both are important erosional processes. Rapid mass wasting events such as massive landslides or debris flows are typically triggered by events that destabilize material that resides on steep slopes. Such events include earthquakes, volcanic eruptions, rain or melting snow, and poorly planned landscape alterations by humans (e.g. road cuts or developments that require the removal of material at the bases of slopes)." [Source: http://www.geology.wisc.edu/courses/lg121/l1ass_wasting.html] Hmm, "landscape alterations"? I’m thinking that putting hundreds of tons of whirling propellers on top of impermeable surfaces in a steep-sloped area subject to wind and water erosion is probably not a well-thought out proposal. [LTR 286, CMT 1]

Response: Please see response to Comment LTR 177, CMT 24 above.

Comment: [In reference to DEIS Section 3.1.1.4, Geologic Hazards, Earthquakes] - “A review of aerial photography’ is NOT doing geology! This is a totally inadequate geologic
analysis. “Inferred” faults shown as dotted lines does not mean that there are NOT buried, subsurface, wide-ranging faults. Ridges have fault lines. I will comment further on the soils issue in a separate memo. [LTR 286, CMT 2]

Response: Please see response to Comment LTR 177, CMT 24 above.

Comment: [In reference to DEIS Section 3.1.2, Proposed Action] - So, are we to gather from the above statement that “further subsurface investigation: has NOT been done, there is NOT a “final tower foundation design that would help determine if there are weak rock or soil layers that could contribute to deep-seated failure of the ridge”?!? And, that this LACK of a final tower foundation design could “provide information on the quality of rock underlying the ridgelines”? Well, I’m confused. Isn’t this DEIS supposed to provide all this information so that a thoughtful, science-based decision can be made by EFSEC and the involved public as to whether this project should even go on? This LACK of information is critical and should be provided in the DEIS. [LTR 286, CMT 3]

Response: Please see response to Comment LTR 177, CMT 24 above.

Comment: [In reference to Section 3.1.1.2] - Above the basalts are a variety of younger volcanic rocks and sedimentary materials that range from... These are materials that contribute to instability on slopes. Need clear topo[graphic] maps that show where turbines are to be placed so the interaction between loose layers and steep slope can be identified. [LTR 178, CMT 78]

Response: Site topography is shown in Figure 3.1-1. Additionally, site topography and geology are shown with the micrositing corridors in Figure 3.1-2.

Comment: [In reference to Section 3.1.2.1] “The steel tower is anchored in a platform of more than a thousand tons of concrete and steel rebar, 30 to 50 feet across and anywhere from 6 to 30 feet deep. Shafts are sometimes driven down farther to help anchor it. Mountain tops must be blasted to accommodate it. The platform is critical to stabilizing the immense weight of the turbine assembly.” This statement is from the National Windwatch article. I really don’t want to see mountain tops “blasted,” and residents near the wind farm proposal probably don’t want to see it, either! The proposed wind farm has 50 some turbines proposed. That is 50 x 1000 tons of concrete and steel rebar = to 50,000 tons of concrete and steel rebar weighing down on soils that are susceptible to erosion; one ton equals 2000 pounds, 2000 pounds x 50,000 tons = 50,000,000 pounds. What are the cumulative impacts of putting 50,000,000 pounds of stress on mountain ridges in Skamania County, and what are the cumulative effects of all the other wind farms’ weights on all the lands and soils in BPA’s area of interest? What does all this weight do to water tables? Any other effects? This issue of weight should be addressed more fully in the DEIS and its lack makes the DEIS inadequate and incomplete. [LTR 281, CMT 20]
Response: As discussed in Section 3.14.3.1, the cumulative impacts of the proposed Project in combination with past, present, and reasonably foreseeable future actions have been analyzed. Reasonably foreseeable future projects do not include other wind facility projects located within Skamania County. The Applicant has no other information on additional reasonably foreseeable future actions in the Project Area. Therefore it is not possible to identify impacts to mountain ridges in Skamania County from possible future wind generation projects that are not reasonably foreseeable. Additionally, as discussed in Section 3.3.2.1, operation of the proposed Project would have minimal or no impacts to groundwater. As discussed above in another response, prior to the final siting process and as a condition of the Site Certificate, a detailed geotechnical investigation of the specific locations of all wind project elements would be conducted.

Comment: [In reference to DEIS Section 3.1.1.4, Geologic Hazards, Earthquakes] - What does "large earthquakes at more distant faults could cause prolonged ground movement at the project site" actually mean? Does that mean that there will be earth movement downhill? Mass wasting? Does this mean that people and wildlife will be affected? How will they be affected? Does this mean that people would have to leave their homes? Are there evacuation routes? Would there be loss of life and property involved in "prolonged ground movement"? These questions are not answered in the DEIS. [LTR 286, CMT 3]

Response: The impact of earthquakes on the proposed Project is discussed in Section 3.1.2.1. Field investigations concluded that the potential for liquefaction is very low at this site and settlement and lateral spread induced by a seismic event would be minimal. Additionally, the potential for surface rupture within the proposed Project Area is small given that there are no mapped faults crossing the site. As discussed above in another response, prior to the final siting process and as a condition of the Site Certificate, a detailed geotechnical investigation of the specific locations of all wind project elements would be conducted.

Comment: Sand, silt, clay particles, and soil will damage aquatic habitat and are considered to be pollutants. Proper disposal of construction debris must be on land in such a manner that debris cannot enter buffers and waters of the state or cause water quality degradation of state waters. During construction, all releases of oils, hydraulic fluids, fuels, other petroleum products, paints, solvents, and other deleterious materials must be contained and removed in a manner that will prevent their discharge to waters and soils of the state. The cleanup of spills should take precedence over other work on the site. Clearing limits and/or any easements or required buffers should be identified and marked in the field, prior to the start of any clearing, grading, or construction. Some suggested methods are staking and flagging or high visibility fencing. A permanent vegetative cover should be established on denuded areas at final grade if they are not otherwise permanently stabilized. All temporary erosion control systems should be designed to contain the runoff from the developed two year, 24-hour design storm without eroding. Coverage under the National Pollution Discharge Elimination System (NPDES) and State Waste Discharge General Permit for Stormwater Discharges Associated with Construction Activities is required for construction sites which disturb an area of one acre or more and which
have or will have a discharge of stormwater to surface water or a storm sewer. [LTR 171, CMT 5]

Response: As discussed in Section 3.1.3 and in other responses a Stormwater Pollution Prevention Plan (SWPPP), an Erosion and Sedimentation Control Plan, and an Environmental Protection Control Plan would be submitted to EFSEC for approval. These plans would include BMPs to minimize erosion and runoff from the Project Area. EFSEC may require the Applicant to obtain coverage under Ecology’s Construction Stormwater General Permit since it would disturb more than 1 acre of land.

Comment: [Within T3N-R9E-S13], there are potential unstable slopes indicated. Applicable [Forest Practice] (FP) rules that may be relevant to the project. Most of these would come into play if there is logging or road building near any waters. 222-16-030, Water typing systems; 222-16-050, Classes of Forest Practices; 222-20-010, Applications and Notifications; 222-24-030, Road construction; 222-24-040, Water crossing structures; 222-24-052, Road maintenance; 222-30-020, Harvest unit planning and designs (wetland management zones); 222-30-022, Eastern Washington RMZs; 222-30-050, Felling and Bucking; 222-30-070, Ground based logging systems. [LTR 172, CMT 12]

Response: Comment acknowledged.

Comment: Mass wasting is a real concern in the proposal area and it has not been adequately addressed in the DEIS. There are real consequences to area residents from erosion and mass wasting events. [LTR 281, CMT 22]

Response: As discussed in Section 2.1.2, final siting of the wind turbines and associated facilities would be done following completion of the EFSEC Site Certificate. Prior to this final siting process, as a condition of the Site Certificate and as discussed in Section 3.1.3, a detailed geotechnical investigation of the specific locations of all wind project elements would be conducted. If this investigation indicates the potential for slope instability at turbine sites or other project facilities such as access roads (including improvements to West Pit Road), these facilities will be redesigned or relocated to avoid this risk. As discussed in Section 2.1.3.7, all road improvements required for the proposed Project would be designed and constructed under the direction of a licensed engineer, in accordance with the Skamania County Private Road Guidelines and Development Assistance Manual. All county roads requiring improvements would be designed and constructed in accordance with the WSDOT Design Manual.

Comment: [In reference to Section 3.1.2.1], “[t]he primary impacts during construction would be potential for erosion, landslides, soil compaction and changes to topography.” IS THAT ALL?!? As the WA State Department of Transportation learned during its rock removal along Highway 14 during the summer of 2010, in Skamania County, when they started an
unintended landslide, there is always the very high potential that once you start moving earth, earth does what it wants to and moves where it wills! [LTR 286, CMT 5]

Response: Please see response to Comment LTR 281, CMT 22 above.

G.3.2 AIR QUALITY

Comment: Once the wind turbine is built, the energy it produces does not cause green house gases or other pollutants. [LTR 1, CMT 4]

Response: Comment acknowledged.

Comment: Because all coal-fired power plants and some natural-gas-fired power plants produce greater emissions when they act as backup systems for wind power, thanks to inefficiencies associated with cycling on and off, the benefits of wind power in reducing carbon emissions are reduced. Contrary to what the DEIS states, there is no evidence that the Whistling Ridge project will have a beneficial impact on air quality in the Columbia Gorge vicinity. No fossil fuel-fired projects will be taken offline as a result. In fact, backup power from fossil-fuel fired projects may be required for those times when the wind is not blowing. Thank you for the opportunity to comment on this project. [LTR 36, CMT 11]

Response: Wind powered generation is dependent on the variable and temporal nature of wind. Therefore, back-up power is indeed required to balance generation variability. BPA, however, has the luxury of an extensive hydro-electric resource which is currently 100% sufficient for balancing the variability of wind-generated power that enters onto BPA transmission lines. In short, 100% of wind power generation has back-up provided by the vast hydro-electric system located in the Pacific Northwest. BPA requires all generators to acquire an amount of reserves (i.e. hydro-electric power). This means that generators must have some potential generation on line that is not generating at that time but can be called upon in an emergency. Currently, BPA supplies that to the wind facilities with the hydro-electric system. Long term, when wind generation exceeds load and energy cannot be stored then alternative solutions are being explored such as hydro pump storage. Pump storage is where water is pumped into a reservoir while generation exceeds load and then power is generated from the stored water when load exceeds generation. Moreover, BPA has hourly schedules (estimates) for how much wind will be generated as well as how much load will be required. So, as load (power consumption) and generation of wind and other sources change, BPA alters the generation at the hydro electric dams. See the BPA fact sheet included at the end of this Response to Comment Section for additional information on this topic.
Comment: [DEIS Section 3.2.2 states that] there would be no emissions from the operation of the turbines. True, but backup would release emissions therefore the operation of the farm would result to increase net emissions in the region. Remedy - Include impacts due to firm power backup, and idling gas plants during wind power operations. [LTR 178, CMT 77]

Response: Please see response to Comment LTR 36, CMT 11 above.

Comment: Gas is a hydrocarbon. Hydrocarbon use produces greenhouse gasses. Greenhouse gasses are known to cause global climate changes. Using “gas-fired reciprocating engines” will produce greenhouse gasses. What is the carbon footprint of these gas-fired reciprocating engines? How many of them would be needed to balance out the unpredictability of wind power generation? What is their cumulative impact on air and water quality? [LTR 279, CMT 17]

Response: Please see response to Comment LTR 36, CMT 11 above.

Comment: [In reference to DEIS Section 3.2.1] - Although this proposed wind farm project itself does not, allegedly, have any “permanent sources of regulated air emission, and no backup generation,” it goes not mean that there are no cumulative impacts on air emissions, because this project is included in BPA’s energy production grid and BPA’s energy production DOES have CUMULATIVE IMPACTS on REGIONAL AIR QUALITY. It is widely known that X amount of wind energy production requires Y amount of gas plant back-up capability because wind energy is notoriously unreliable and BPA cannot have unreliable sources of energy in the grid. It creates havoc among users and I’m pretty sure it negatively affects BPA’s machinery. The effects of wind power on the grid and on the actual BPA hard infrastructure is not addressed in the DEIS and it should be. The public should be aware if there are any dangers associated with the influx of large amounts of energy from wind farms in the energy grid and if the grid and reliably balance this energy influx without hardware meltdowns. BPA should have addressed these issues in the DEIS and their failure to do so is just another fatal flaw in this fatally flawed DEIS. [LTR 286, CMT 11]

Response: Please see response to Comment LTR 36, CMT 11 above.

Comment: [In reference to DEIS Section 3.2.1] - The statement “production of electricity from wind produces no direct emissions of greenhouse gasses or other air pollutant” is spurious. The DEIS does not provide any details on what huge propeller-like blades do to the air and what if any, gasses are produced by the machinery that is used to run the wind towers. The DEIS does not provide any details on how many gas plants are used by BPA to manage the flexibility and balance of the influx of unreliable wind power generated by all the wind farms producing energy and trying to get it onto our energy grid. If the capability of the hydro system to incorporate wind power will be fully utilized in a couple of years, as the NW Energy Council has stated, then
the option to use existing gas-fired power plants, unidentified in the DEIS, would be used to integrate wind more fully into the energy grid. Where are these plants located? How much CO2 do they produce? What is their carbon footprint? What is global climate change negatively affects the winds that are not powering some of these wind farms, will more and more gas-fired plants have to be brought online, thus eliminating any benefits that may accrue to wind power? Where is BPA’s Wind Integration documentation? If, as the NW Energy Council states, we can achieve 85% of load growth can be met, through the use of technologically proven efficiencies in our homes, commercial spaces, lighting, etc., then why do we need so many wind farms and gas plants that degrade our environment and our quality of life? These questions need to be answered in the DEIS. The NW Energy Council sees conservation and “improved efficiency of electric use” as the best choice for the region. See the Sixth NW Electric Power and Conservation Plan Overview, put out by the NW Energy Council. [LTR 286, CMT 13]

Response: Please see response to Comment LTR 36, CMT 11 above. No emissions result from wind powered turbines and 100% of wind generation has back-up provided by the vast hydro-electric system within the Pacific Northwest. Therefore, no coal, gas, or any other new generation facility would be required as a result of the proposed Whistling Ridge Project. Although a significant percentage of future load growth may be achieved via various efficiencies, wind generation is a piece of the puzzle that collectively will meet electric load growth within the Pacific Northwest. Please refer to Section 1.4.2 for a discussion of the No Action Alternative.

Comment: [In reference to the Whistling Ridge Energy Project] - It also decreases the carbon footprint that a coal fired plant would use to produce 75 MW of power which our growing population state needs. [LTR 37, CMT 5]

Response: Comment acknowledged.

Comment: We have a short time in to impact our dire global situation, and we must replace other harmful polluting means of producing energy. [LTR 40, CMT 7]

Response: Comment acknowledged.

Comment: The DEIS [misrepresents] the climate change and air quality impacts of the project and of the no-action alternative. The DEIS repeatedly asserts that if the Whistling Ridge Energy Project is not built, then adverse impacts to climate change and air quality would necessarily result. For example, the DEIS states that “[i]f the No Action Alternative is selected, the growing electricity needs of the region would continue to be met through a combination of other renewable development and a combination of additional fossil fuels.” DEIS [on pages] 3-21 [through] 3-22. This completely false dilemma, in various forms, is repeated throughout the DEIS without any factual support. In fact, the regional energy system will reduce greenhouse
gas emissions and air pollutants regardless of whether this individual project is built, and primarily through conservation measures. The Northwest Power Planning Council’s Sixth Power Plan, which will dictate the portfolio of energy production sources for the foreseeable future, has planned to meet 85% of new demand with conservation and efficiency measures over the next 20 years. Sixth Northwest Power Plan Overview at 1. The remaining 15% of new demand would be met with renewables. Notably, this would be achieved even while the Boardman coal-fired power plant is taken offline by 2020. The Bright Future Report also provides some broader context for the supply and demand aspects of the regional energy grid. Bright Future Report, NW Energy Coalitions, Original Edition, March 2009 – Update 1, July 2009. The Bright Future Report analyzes how the region will meet its energy needs through 2050, factoring in the loss of the Boardman coal-fired power plant, the removal or reduced use of hydropower projects on the lower Snake River, and picking up that lost energy supply through conservation, efficiency, and clean new sources of energy. The Report’s bottom line conclusions are that “[t]he region has enough renewable potential to more than meet all current and future power needs” and that the potential for affordable clean energy “[d]warfs” the need. Bright Future Update at 14, 15. Thus, foregoing the 21 average MW of production capacity that would result if the Whistling Ridge project is not constructed would be essentially irrelevant to the overall supply of alternative energy. Furthermore, there is absolutely no evidence in the record showing that the alternative to this particular wind project is continued use of fossil-fuel generation sources or new fossil-fuel generation sources. The real choice is between this particular wind facility and siting other wind facilities in alternative locations with fewer environmental impacts. Thus, it is inappropriate for the DEIS to compare the likely impacts of a wind energy development to the impacts of fossil-fuel generation sources. The region’s climate change goals and air quality goals will be achieved regardless of whether the Whistling Ridge project is constructed. Every statement asserting the false dichotomy between constructing the project and a future with higher carbon emissions and air quality problems must be removed from the DEIS. [LTR 179, CMT 81]

Response: Please refer to Section 1.2 for a discussion of the purpose and need of the Project. Indeed the number 1 option described by The Northwest Power Planning Council's Sixth Power Plan is for cost-effective efficiencies. The number 2 option, however, is the development of renewable resources, namely wind power. Although, the integration of wind generation poses load management challenges, BPA has developed a diverse strategy to overcome such challenges and continues to support the transmission of clean, inexpensive power. Additionally, in order to accommodate increased demand for clean, renewable energy, BPA has instigated lofty efforts to bring over 6,000-MWs of wind power generation online by 2013. See the BPA fact sheet included at the end of this Response to Comment Section for additional information on this topic.

Comment: [In reference to Section 3.2, Air Quality] - Qing Chen, (360) 407-6809, is available to address concerns related to] Best Management Practice for minimization of track out and windblown dust should be required in applicable permitting. [Whereas, Connie Groven, (360) 407-625, is available to discuss any toxics cleanup. Otherwise], there are no new comments submitted at this time. [LTR 187, CMT 1]
Response: Section 3.2.3 identifies several mitigation measures to avoid, minimize, and compensate for potential construction-related air emissions and dust impacts.

Comment: [Regarding] climate change - we recognize the significant threat climate change poses to birds and bird habitat, including threatened and endangered bird species. That is why we support well-designed, appropriately sited renewable energy projects as a critical step in reducing carbon emissions. Seattle Audubon is greatly encouraged by the potential for this project to avoid the emissions from combustion of an estimated 114,000 barrels of crude oil or 654 million cubic feet of natural gas, leading to the displacement of over 131,000 tons of carbon dioxide annually. (DEIS at 3-20) The beneficial biological impact of such a displacement to birds and other wildlife in the region appears significant. It is also important to evaluate how the project’s contribution to reducing carbon emissions would in turn impact at-risk species in the region such as the northern spotted owl. For example, climate change models predict that as a result of global warming, the Pacific Northwest will experience warmer and drier summers, thereby reducing the food supply for owls, as well as colder and wetter springs, resulting in a reduction in the survival chances of owl fledglings during nesting season (for more details, see http://ir.library.oregonstate.edu/jspui/bitstream/1957/11326/1/EGlennDisseration2009.pdf). While hard to quantify precisely, the FEIS should better evaluate the trade-off between potential benefits from the project to birds from avoided emissions (through reduced carbon output and the resulting effects on forest habitat and food supply) and the potential harm from the project to birds (through loss of existing habitat, habitat fragmentation and potential collision mortality). Your two agencies, together with the project proponent, are well positioned to facilitate a Northwest-specific study comparing the annual bird fatalities caused by wind farms versus those caused by fossil-fueled power stations, similar to the Sovacool study. (DEIS p. 3-276) [LTR 196, CMT 3]

Response: While the proposed Project has the potential to offset emissions from combustion of an estimated 114,000 barrels of crude oil or 654 million cubic feet of natural gas, leading to the displacement of over 131,000 tons of carbon dioxide annually, it is beyond the scope of this EIS to evaluate how the Project’s contribution to reducing carbon emissions would in turn impact at-risk species in the region such as the northern spotted owl. It could be concluded that the displacement of 131,000 tons of carbon dioxide annually would have a beneficial biological impact on at-risk species to the degree that changes to existing bird and wildlife habitat from global climate change are moderated. It would be overly speculative to estimate the trade-off between potential benefits from the Project to birds from avoided emissions (through reduced carbon output and the resulting effects on forest habitat and food supply) and the potential harm from the Project to birds (through loss of existing habitat, habitat fragmentation and potential collision mortality). The most that could be concluded would be that the benefits to at-risk species from carbon displacement would potentially offset potential harm from the Project to birds (through loss of existing habitat, habitat fragmentation and potential collision mortality).
Comment: About this time these objections are usually dismissed with the argument that we must save the world from green house gasses. The problem is that wind power will not accomplish that. Because wind power only produces energy when the wind Is blowing - and even then it produces variable energy - it must have 100% back-up by conventional or nuclear energy sources. In this way, wind power is in fact driving the need for gas (preferred source) electrical plants that produce a lot of green house gasses. [LTR 256, CMT 6]

Response: It is true that wind generation requires back-up energy sources, however BPA currently supplies balancing generation from hydro power. Wind generation in the northwest may require additional backing sources in the future, but at this time are not ‘driving the need for gas (preferred source) electrical plants within BPA’s balancing authorities.

Comment: So, now we have come to the crux of the wind generation matter—wind is not a reliable source of energy and needs backup from “natural gas-fired generators; storage resources such as pumped-storage hydro plants; and utility demand response programs…natural gas-fired turbines and reciprocating engines appear to be good options.” What is the carbon footprint of these backup systems? [LTR 279, CMT 14]

Response: While these are excellent questions, they are speculative in nature and fall beyond the scope of this EIS. If BPA receives a request to interconnect new generation to the transmission system, back-up or otherwise, each request will be reviewed on a case by case basis and subject to review under NEPA. Furthermore, 100% of wind generation has back-up provided by the vast hydro-electric system within the Pacific Northwest. Therefore, no coal, gas, or any other new generation facility would be required as a result of the proposed Whistling Ridge Project.

Comment: [In reference to Section 3.2.1] - Just because the DEIS states that “Skamania County does not have any nonattainment areas for air quality” does not mean that the air quality in the Columbia River Gorge is good. The OR department of Environmental Quality and the SW Clean Air Agency have been working for many years on the issue of increasing haze and air quality in the Gorge and the surrounding environments. Most people who reside in the area or swim in the Columbia River will tell you that they have noticed a degradation of the air and water quality. These issues have not been adequately addressed by any government agency, to date. Which does not mean that air (or water) quality of the Gorge is good or bad, from a science viewpoint. It means that it needs to be thoroughly investigated and analyzed. The DEIS fails to do any adequate air [or water] cumulative impacts analyses. [LTR 286, CMT 10]

Response: Please refer to the Background Air Quality section within Section 3.2.1. Air quality in the Project Area is influenced by a variety of sources including power plant emissions, woodstoves, motor vehicles, ships, trucks, agriculture, and other industrial activities. The well-documented haze problem within the Columbia Gorge is largely caused by winter stagnations that trap pollutants and fog, and by westerly winds transporting emissions from the Portland metropolitan area. No air emissions result from wind turbine operation as no fuel is being
burned. Air emissions would occur during construction activities, but these emissions would be temporary in nature and minor relative to other industrial activities (e.g., logging, manufacturing) and therefore would not have a notable effect on long-term air quality.

**Comment:** [In reference to DEIS Section 3.2.1] - “Half of all emissions from energy-related activities come from large stationary sources such as power plants” is not a reassuring statement. Half means 50 percent, that is 50%. This is not a small amount. The DEIS does not state, as far as I was able to ascertain, how much BPA contributes to greenhouse gases through its entire energy production process. How many power plants back up BPA's hydro-energy production when there is not enough water, or fish protections prohibit BPA from dumping water over the dam? What is BPA's calculated carbon footprint? Why didn't BPA calculate its total carbon footprint for the DEIS? This is another fatal flaw in this document. The statement that hydropower "produces less carbon dioxide per MW-hour than any other region in the United States" is NOT a conclusive statement about BPA's or the wind farms' total cumulative contribution to greenhouse gases! LESS does not mean that BPA and Whistling Ridge and all the other energy production facilities in the region do not contribute CO2 to the total footprint. BPA needs to calculate its cumulative carbon footprint from ALL its energy production facilities and processes. Then we call start to talk about carbon footprints. [LTR 286, CMT 12]

**Response:** It is important to note that BPA provides transmission services to electrical generation facilities, but does not own or operate any generation facilities. Additionally, the scope of this EIS relates specifically to the Whistling Ridge Wind Energy Project and is not intended to document impacts from other sources. Nevertheless, BPA has made it a priority to quantify GHG emissions associated with all of the agencies activities. As discussed on page 3-17 and 3-18 of the DEIS, BPA has already prepared a climate change roadmap and plans to release annual GHG inventory reports beginning in 2010.

**Comment:** [In reference to DEIS Section 3.2.1] - The state initiative to lower greenhouse gases by 2020 through the use of renewable energy sources, while admirable, is perhaps not the only and best way to achieve reduction of greenhouse gases. Going green is not a concept carved in cement. Our ideas can evolve and we can change our minds if a better and safer ideas and technology comes along. [LTR 286, CMT 15]

**Response:** Comment acknowledged.

**Comment:** [In reference to DEIS Section 3.2.1] - Where is this document in the DEIS? I was not able to find it. This should be part of the DEIS and if it isn't then the DEIS is not adequate and should not have been rushed out for public comment. This is a critical report on BPA’s carbon footprint. One rationale for all of these regional wind farms is that they produce less CO2 than other types of energy production facilities and therefore have less of a carbon footprint. Well, we don't really know that, do we? There is nothing in the DEIS that would lead to this
conclusion, at least nothing based on facts and figures. All of BPA’s greenhouse gas-cal/sing
activities SHOULD be in the DEIS, so that a comparison can be made based on facts and
figures. [LTR 286, CMT 16]

Response: As stated on DEIS page 3-17, “This document” refers to BPA’s climate change
road map which can be located at:
also see the response to Comment LTR 286, CMT 12 above. Wind powered turbines do not
produce any CO2 as they are solely powered by wind. Therefore, they have a smaller carbon
footprint than any combustion generation facility.

Comment: [In reference to DEIS Section 3.2.2] – So, nitrogen oxides, hydrocarbons, carbon
dioxide, particulate matter, and sulfur dioxide would be the primary air pollutants, plus more
particulate matter produced by the rock crusher and batch plants! What quantity of each of these
would be produced? How much particulate matter would go into our air and affect air quality?
Where is the data (and some hard numbers so that we can see what quality of these “primary air
pollutants” will be produced! Where are the cumulative impacts analyses on our regional air'
and water quality to see how much air and water pollution this project would contribute to our
region? There is nothing here to compare, assess, and analyze. This is a DEIS deficiency. [LTR
286, CMT 17]

Response: As discussed in Section 3.2.2, the primary air pollutants from diesel-powered
equipment would be nitrogen oxides, hydrocarbons, carbon dioxide, particulate matter (PM) and
sulfur dioxide. In addition to these, the rock crusher and batch plant(s) would produce additional
PM. These emissions would be similar in nature to those produced by any construction project
that involves heavy equipment and transportation of materials to the Project Area. These
construction emissions would be temporary and would be limited to the areas adjacent to the
construction site. They would not affect a substantial number of persons or persist for an
extended period of time and would not result in exceedance of any air quality standards.

Comment: [In reference to DEIS Section 3.2.2] – So what does “wind energy’s carbon
dioxide emissions are on the order of 1 percent of coal or 2 percent of natural gas per unit of
electricity generated” actually mean? This statement doesn’t mean anything without data to
compare. Where are the comparison charts for wind, gas, and coal CO2 emissions? I could not
find them in the DEIS. [LTR 286, CMT 19]

Response: The sentence, “The American Wind Energy Association estimates that including
generation from all sources, wind energy’s carbon dioxide emissions are on the order of 1 percent
of coal or 2 percent of natural gas per unit of electricity generated (AWEA 2009),” on page 3-21
has been removed from the EIS.
Comment: [In reference to DEIS Section 3.9.2.2] - It is now accepted (OSU and other universities, scientific studies, etc.) that old growth trees sequester more CO2 than younger trees. The age when young trees begin to become part of the sequestration cycle of CO2 is fifteen years. So, the harvesting of the older trees and the replanting with seedlings would actually put MORE CO2 into the atmosphere. This must be computed into the total carbon footprint of this project; it must also be considered when calculating BPA’s carbon footprint. [LTR 286, CMT 59]

Response: Discussing the theoretical sequestering of carbon dioxide from old-growth trees versus that of seedlings in addition to forestry practices are out of the scope of this EIS.

Comment: Wind farm proponents talk about turbines as if they are do not change air quality, but propellers whirling around do change the chemical composition of air. Where is the analysis to look at this air quality issue? Wind turbines can change the flow of wind in the area where they are located. How do wind turbines changing local wind patterns affect the local area? How does it affect crops? Rainfall? [LTR 314, CMT 7]

Response: Wind turbine operation, including propeller rotation, does not emit any air pollutant nor is there any scientific basis suggesting that it modifies the chemical composition of air. In addition, research suggesting wind facilities influence weather patterns is preliminary and is not considered viable at this time. If future research concludes the contrary, then localized and global meteorological studies would be considered.
BPA’s wind power efforts surge forward

As the nation seeks new sources of clean electricity, wind has emerged as the most mature and promising new resource. It is free of CO₂ emissions, relatively cost effective compared to other new generating resources and is, thus far, the most viable non-hydro renewable resource available on a large scale. Its assimilation into the U.S. and Pacific Northwest generation resource base is advancing rapidly, thanks to concerted efforts to meet and overcome challenges to dealing with wind’s variability.

Others, primarily independent companies, are developing wind resources. The Bonneville Power Administration’s major role is to provide the reliable transmission that delivers electricity from wind farms, often located in remote areas, to the region’s communities. Bringing a variable and difficult to predict energy resource, such as wind, onto the power grid in large amounts is one of the great engineering and economic challenges in the power industry today. BPA is maintaining a remarkable pace of connecting wind power into its transmission system and has among the highest levels of wind power in its transmission system compared to load of any grid balancing authority in the country.

Growth rate fuels progress

All but one of the states in BPA’s service territory have enacted renewable electric generation standards for their retail utilities. These requirements, coupled with those of other Western states, have set off a “gold rush” of wind developers to the region.

The growth rate of wind interconnections is astounding. In 2009 alone, the amount of wind power integrated into BPA’s transmission system went from 1,500 megawatts to more than 2,500 megawatts. It is now above 2,700 megawatts. In the next two years, BPA expects a near doubling of wind on its system. By 2013, BPA may have more than 6,000 MW of wind power on its system.

As wind power continues to grow, the energy industry faces dramatic change. This is an exciting time for the industry, and BPA is helping lead the nation into a new age of renewable power.

BPA and the region’s wind community have been working aggressively to adapt to wind power’s rapid growth. In 2009, the agency released an accelerated

Projected Wind Projects Connected to BPA Grid on Existing Queue and Recent Trends

Northwest wind power is growing fast.
18-month work plan for wind integration activities. BPA's Wind Integration Team is tackling five projects to better manage large amounts of wind power in BPA's balancing authority area. All of these projects, summarized below, are on or ahead of schedule.

Making it work
Given the challenges, how can 6,000 megawatts of wind, and perhaps more ultimately, operate in a balancing area with just under 11,000 megawatts of peak load? BPA is focusing its efforts in four areas to make it work.
- Building transmission to support wind integration.
- Using existing transmission capacity in new ways.
- Exploring new sources of generation capacity reserves.
- Developing partnerships with other utilities and the wind power community.

Building transmission to support wind integration
The region needs new transmission to meet growing demand for energy, particularly renewable energy. Because BPA owns and operates three-quarters of the region's high-voltage transmission, the agency plays a vital role in facilitating the development of renewable energy. Simply put, wind and other resources will not be developed unless transmission is available to get those resources to market. This is particularly challenging because, on average, wind projects in the BPA service territory only operate at about 30 percent of their capacity.

To determine transmission needed to support additional wind generation, as well as to shore up reliability, BPA initiated a new process called Network Open Season in 2008 to better manage the queue of customers seeking BPA's transmission services. Previously, many potential developers had sought to reserve transmission for plants still in the planning stage or plants that might never be built. The result was a long and unmanageable queue. Under Network Open Season, BPA offers firm network transmission service to customers who request it, but the customers must make a financial commitment for that service. This winnows out the speculative requests for transmission. In 2009, BPA confirmed financial commitments for 6,410 megawatts of transmission service requests. Three-quarters of the requested service capacity were for wind generation.

BPA was able to accommodate more than 20 percent of the requests with existing capacity. It was also able to offer a new “conditional firm service” to provide still more transmission service from existing capacity of the system. Conditional firm allows some curtailing of service under certain conditions. This allowed BPA to make the most efficient use of its existing system before proposing new construction.

Network Open Season did show, however, that BPA needs to move forward with four new transmission projects. Together, these projects would bring 1,800 megawatts of new wind generation to the region.

Changing grid management for wind power integration
BPA's Wind Integration Team is developing new processes and systems to bring as much efficiency as possible out of existing transmission and generating reserve assets. Basically, BPA is stretching the capability of the existing system through efficiencies from operational improvements. If these initiatives succeed and are implemented over the long term,
they could make a significant dent in the amount of balancing reserves needed to support a tripling of the wind generation interconnected to BPA's system.

**New protocols manage extreme wind ramps**

BPA has seen unscheduled wind generation swings of more than 1,000 megawatts in less than an hour on its system. New operating protocols introduced in 2009 help manage sudden fluctuations in wind generation. When wind picks up and unscheduled generation threatens to deplete BPA's balancing reserves, BPA dispatch now automatically sends an electronic signal to wind plants to reduce their generation to scheduled levels. So far, BPA dispatchers have applied the protocols several times a month. Likewise, when large decreases in scheduled wind generation deplete BPA's ability to provide balancing energy, BPA revises the wind schedules downward, and receiving utilities must make up the difference with their own resources.

**Shorter scheduling intervals**

Historically, utilities schedule power deliveries by the hour. As a pilot project, BPA is allowing within-hour changes to power schedules for wind projects that are exceeding their hourly schedule. Intra-hour scheduling can help wind generators avoid curtailment of excess generation and could make it possible for them to sell excess power that otherwise might be limited. This has the potential to help reduce reserve requirements and generation imbalance charges. BPA is evaluating possible expansion of this project.
The challenge

Wind is a variable power resource that is hard to predict. That’s a challenge because, unless generation matches demand second by second, the transmission system will destabilize. If the system becomes unbalanced, blackouts can result. Think of it in terms of a computer. We use surge protectors to prevent a sudden increase in electricity. Some sensitive electronic equipment also incorporates voltage sag protectors. Without these protections, equipment can suffer the equivalent of a “blackout.”

To maintain system balance in the high-voltage grid, utilities use balancing reserves, or generation held available to manage fluctuations between power load and power generation. In the Northwest, the hydro system has historically provided all the balancing reserves we need, because hydro generation can be increased or decreased quickly. But the hydro system has limits. To support continued large-scale wind power growth, we are learning to operate the existing system in new ways.

As with most coastal climates, Northwest winds are not steady. They tend to ramp up or down quickly and often unexpectedly. System operators are inventing new techniques to maintain the constant balance needed between power loads and generation levels. Some solutions already have been put in practice; others are on the way.

BPA Balancing Authority Load & Total Wind Generation
March 3-10, 2010

BPA now operates the hydro system to respond to and balance both variations in power loads and unexpected changes — up and down — in wind power output.
New wind forecasting applications

Wind output is difficult to predict, making it hard to schedule accurately. This uncertainty increases the amount of reserves BPA must hold to keep loads and generation in balance. BPA has installed 14 anemometers throughout the region to better predict wind availability and is using the data to develop a more accurate wind power forecast system for the Columbia Basin.

Dynamic transfer

Dynamic transfer is one of the most important techniques to reliably and cost-effectively integrate large amounts of variable renewable generation resources. This technique would allow a dispatcher in one balancing authority to control and take responsibility for supplying balancing reserves for a generator located in another balancing authority. A study identifying available dynamic transfer capacity on 11 key transmission paths completed in February 2010 found moderate amounts of available dynamic transfer capability. BPA is making this capability available to its customers on a pilot basis.

Managing large wind fleets is proving most efficient when handled across large geographic areas.

Customer-supplied imbalance reserves

Also known as self-supply, this project would allow wind generators in the BPA balancing authority area to supply their own imbalance reserves rather than relying on BPA for such services. BPA plans to launch this project on a pilot basis in October 2010, once the necessary technical adjustments are in place on both BPA and participating wind project systems. Wind project owners likely will use the Joint Initiative’s Dynamic Scheduling System to facilitate supplying their reserves.

There are more than 30 discrete balancing authorities in the Western Electricity Coordinating Council.

Exploring generation capacity reserves

Wind project operators in BPA’s balancing authority pay for integration services for their projects, so that the consumers who pay to purchase wind power both receive the benefits of wind power and pay the costs of the resource. For 2010-2011, the rate reflects the costs of generation imbalance reserves provided from federal hydropower resources.

As the wind resource grows, even with efficiencies, new resources likely will be needed to provide balancing services for variable renewable resources. In preparation, BPA has begun to explore options for adding flexibility capacity.

Key terms

Balancing Authority: A balancing authority is an entity that is responsible for maintaining a constant balance between power load and power generation in a geographic area. It is usually a utility or other transmission provider such as a regional transmission organization. There are 14 balancing authorities in the Pacific Northwest. BPA’s balancing authority area includes primarily rural portions of Oregon and Washington, plus small portions of northern Idaho and northwest Montana.

Balancing Reserves: Generation held available to be ready to use if needed to maintain the balance between power load and power generation as loads fluctuate and/or as real-time generation differs from scheduled generation.
Part of a much larger picture

Most of the Northwest’s wind generation is in rural portions of eastern Oregon and Washington, while most consumers of wind power are in larger metropolitan areas in balancing authorities managed by other utilities. Worldwide, managing large wind fleets is proving most efficient when handled in unified systems that cover large geographic areas with millions of people and many, diverse power sources, such as in Spain and Texas.

Utilities in the Northwest are working together to realize similar benefits across their smaller balancing authorities. BPA is among many Western utilities participating in a Joint Initiative of ColumbiaGrid, WestConnect and the Northern Tier Transmission Group — entities managing and coordinating some transmission issues among utilities — to develop common approaches to wind integration. For example, the Joint Initiative is creating a common system for dynamically scheduling control of a wind generator from a resident balancing authority to another balancing authority where the wind power is being consumed.

On a still larger scale, utilities throughout the Western Interconnection — the interconnected power system of the Western United States, British Columbia, Alberta and small parts of Mexico — are working to redesign transmission and power resource planning and adapt the way the grid works to help meet state and national renewable power objectives. The Western Electricity Coordinating Council, the reliability organization for the Western Interconnection, is leading this effort.

BPA is the balancing authority responsible for maintaining a constant balance between the power load and power generation in the area shown in map. (A balancing authority is also known as a control area.) Most of the wind power on line and planned for the Pacific Northwest is clustered in BPA’s balancing authority at the eastern end of the Columbia River Gorge. However, 60 percent of the wind power in BPA’s balancing authority area serves loads in other utilities’ balancing authorities.
Energy storage technologies could be a valuable source of such flexibility to the degree they can absorb excess wind energy when it is not needed and return it to the grid during periods of greater demand. For example, BPA is working with the Pacific Northwest National Laboratory on its study of various options including pumped storage, compressed air storage, batteries, and flywheels. PNNL is also examining residential applications such as hot water heaters as potential sources of energy storage for the grid.

BPA is working with the U.S. Army Corps of Engineers and the Bureau of Reclamation on the potential for pumped hydro storage in the Northwest. This represents a new application of an existing but evolving technology that could help fill the need for more frequent uses of ramping generation to respond to wind variability.

Follow our progress
To follow BPA’s wind integration work or participate in its efforts, go to www.bpa.gov/wind, contact Eric King at eking@bpa.gov or call BPA at 1-800-622-4610.

BPA Balancing Authority — Total Wind Generation and Wind Baseline
Feb. 25–March 4, 2010

Balancing Authority Load  Wind Generation

Scheduling wind power to track closely to nature’s changes in wind speed is a challenge. Blue line is actual generation, red is wind power scheduled in BPA’s balancing authority.
G.3.3 WATER RESOURCES

Comment: [In reference to DEIS Section 3.3.1.1] – There is no mention of the unnamed stream west (and down slope) of the A1-A7 turbine group. This stream initiates as a spring and flows year round, and eventually empties into the Columbia River. In addition, it flows through World Stewardship Nature Preserve land (soon to be purchased by Columbia Land Trust). Please add this consideration to your study. [LTR 60, CMT 2]

Response: All known and field verified surface water resources in and near the Project Area (including those west and down slope of the A1-A7 turbine string) are shown in Figure 3.3-1. Most of these drainages are small perennials streams or seasonal streams with short periods of spring or storm runoff. The construction and operation of the wind turbines, access roads, and other project features are not anticipated to impact surface or ground water resources in or near the Project Area.

Comment: [In reference to DEIS Section 3.3.1.3], the same unnamed stream mentioned above has been overlooked since it does originate at groundwater. Please add this to your study. [LTR 60, CMT 3]

Response: Please see response to Comment LTR 60, CMT 2 above.

Comment: The geologic and soils information is troubling even when one has seen the steep hillsides that this project proposes to disturb. Construction will require blasting, which can destabilize fragile habitats, and unpredictable effects may result over large periods of time. The soil types present at or immediately adjacent to the construction sites are not stable and the planned mitigation measures which aim to control erosion and slides may be difficult, if not impossible to achieve, as can be already seen at numerous locations in this portion of the country. Although downplayed in the EIS, significant erosion events will surely degrade water quality and adversely affect downstream functions as well as local aquatic invertebrate populations. [LTR 76, CMT 6]

Response: Please see response to Comment LTR 60, CMT 2 above.

Comment: [In reference to DEIS Section 3.3.1.1] - There is no mention of the unnamed stream east (and down slope) of the A1-A7 turbine group. This stream initiates as a spring and flows year round, and eventually empties into the Columbia River. In addition, it flows through World Stewardship Nature Preserve Land (soon to be purchased by Columbia Land Trust). Please add this consideration to your study. [In reference to DEIS Section 3.3.1.3], the same
unnamed stream mentioned above has been overlooked since it does originate at groundwater. Eliminating the A1-A7 turbine would eliminate any effects on the following factors would eliminate the impact to these important water resources. [LTR 124, CMT 2]

Response: Please see response to Comment LTR 60, CMT 2 above.

Comment: There is no mention of the unmapped stream west and down slope of the A-1 through A-7 turbine group. This stream initiates as a spring and flows year around and eventually into the Columbia. In addition, it flows through World Stewardship Nature Preserve Land which will soon be purchased by Columbia Land Trust. Please add this consideration to your study. [LTR 317, CMT 23]

Response: Please see response to Comment LTR 60, CMT 2 above.

Comment: On ground water the same unmapped stream mentioned above has been overlooked since it doesn’t originate as ground water and springs. Please add that to your study. [LTR 317, CMT 24]

Response: Please see response to Comment LTR 60, CMT 2 above.

Comment: We are also concerned about whether there will be effects to groundwater and surface water. We request that the EIS carefully evaluate what effects the Project would have on wildlife and the ecosystem. [LTR 119, CMT 7]

Response: The Water Resources section addresses surface water (Section 3.3.1.1, DEIS page 3-24) and groundwater issues (Section 3.3.1.3, DEIS page 3-26). The impacts to surface waters and groundwater are listed in Section 3.3.2.1 and state that “Temporary roadways would be built to provide additional access for heavy machinery during construction. Of these improvements, only the planned improvement to West Pit Road may directly affect water resources.”

Comment: In reference to DEIS Section 3.3.1.3, this section lacks sufficient information on the existing groundwater environment to support the finding of little or no impact. Suggest the section more fully address the depth to groundwater, flow direction, and transmissivity (permeability) of the aquifer as it relates to possible affects on the area domestic and agricultural ground-water resources (also see DEIS Section 3.3.1.5). Helsel et.al. (2002) is a good reference for this type of analysis. Pg. 3-29: Because [S]ection 3.3.3 addresses mitigation procedures for the isolation of groundwater from chemical spills, we assume that chemicals will be present on site during both construction and operation. Suggest the document include a discussion of potential chemical spills, and aquifer transmissivity (permeability), as it relates to...
the potential movement of contaminants toward nearby domestic or agricultural water wells. [LTR 164, CMT 4]

Response: As mentioned in Section 5.4.2 of the geotechnical report prepared in support of the Application for Site Certification, during the excavation of test pits at the site, no ground water was encountered up to a depth of 16 feet below ground surface. Presence of groundwater will be determined during subsequent geotechnical investigations to be performed in support of final foundation design. Potential spills to groundwater during construction would be controlled through standard construction BMP’s. A Spill Prevention, Control and Countermeasure (SPCC) Plan will be prepared prior to construction.

Comment: [In reference to Section 3.3] - Roberta Woods, (360) 407-6269, [is available to address concerns related to] any discharge of sediment-laden runoff or other pollutants to waters of the state [as governed by Chapter 90.48 RCW, Water Pollution Control, and WAC 173-201A, Water Quality Standards for Surface Waters of the State of Washington]. Erosion control measures must be in place prior to any clearing, grading, or construction. These control measures must be effective to prevent stormwater runoff from carrying soil and other pollutants into surface water or storm drains that lead to waters of the state. [LTR 171, CMT 4]

Response: Coordination efforts with Washington Department of Ecology will be made to ensure that erosion control practices are in place prior to any construction activities if this proposed Project were to move forward. Furthermore, as discussed in Section 3.1.3, EFSEC will require the Applicant to obtain coverage under Ecology's Construction Stormwater General Permit. The Stormwater General Permit (NPDES) will include BMPs to minimize erosion and runoff from Project Areas.

Comment: [In reference to Section 3.3] - Vicki Cline, (360) 407-0278, [is available to address concerns related to] all water wells shall be constructed in accordance with the provisions of Chapter 173-160 WAC by a driller licensed in the State of Washington. Well reports must be submitted to Ecology within 30 days after completion of a well. All water wells that may be drilled must be a minimum of 100 feet from any known, suspected, or potential source of contamination. Wells shall not be located within 1,000 feet of a solid waste landfill. WAC 173-160-171(1) The proposed water well shall be located where it is not subject to ponding and is not in the floodway, except as provided in Chapter 86.16 RCW. (2) It shall be protected from a one hundred year flood and from any surface or subsurface drainage capable of impairing the quality of the ground water supply. The Growth Management Act (Section 63) requires an applicant to submit evidence of an adequate water supply before a building permit can be issued for any building requiring potable water. Any ground water withdrawals anticipated exceeding 5,000 gallons a day for domestic uses or for commercial/industrial uses
require a water right permit. Any modification to existing water rights must be approved by Ecology’s Water Resources Program. [LTR 187, CMT 3]

Response: The O&M facility will include a water well exempt pursuant to RCW 90.44.050 (withdrawing less than 5,000 gallons per day) for water supply. Sanitary wastewater from the maintenance facility will be discharged to an on-site septic system. The RCW reference on page 3-28 in the DEIS has been revised to reflect the correct citation.

Comment: The DEIS indicates that water quality may be adversely affected if construction alters the hydrology of springs and surface runoff such that erosion carries sediment to nearby waterbodies. We recommend that this aspect of the project be monitored to assure that water quality is protected. Please also note that anti degradation provisions of the Clean Water Act apply to those waterbodies where water quality standards are currently being met, and prohibit degradation of their water quality. [LTR 189, CMT 6]

Response: Mitigation measures related to erosion control and their potential effect on water quality standards are discussed in both the Earth section (Section 3.1.3) as well as the Water Resources section (Section 3.3.3). Furthermore, for any Project construction activities, EFSEC will require the Applicant to obtain coverage under Washington Department of Ecology’s Construction Stormwater General Permit. No later than sixty (60) days prior to the beginning of Site Preparation, the Certificate Holder would develop and submit for EFSEC approval a Construction Stormwater Pollution Prevention Plan (Construction SWPPP). The Construction SWPPP would meet the requirements of the Ecology stormwater pollution prevention program (chapter 173-230 WAC), and the objectives and requirements in Special Condition S.9. of the National Pollutant Discharge Elimination System and State Waste Discharge General Permit for Stormwater Discharges Associated with Construction Activities issued by the Department of Ecology on November 16, 2005 or as revised. The Certificate Holder would not begin Site Preparation prior to obtaining Council approval of the Construction SWPPP. The Construction SWPPP would include measures for temporary erosion and sedimentation control. The Construction SWPPP would identify a regular inspection and maintenance schedule for all erosion control structures. The schedule would include inspections after significant rainfall events. Any damaged structures would be addressed immediately. Inspections, and subsequent erosion control structure corrections, would be documented in writing and available for EFSEC’s review on request.

Construction activities in the State of Washington related to the construction of the BPA substation is overseen by EPA. EPA retains enforcement and permitting authority for Federal facilities. BPA would prepare and implement a Stormwater Pollution Prevention Plan (SWPPP) to control stormwater pollution associated with construction activities. The SWPPP would be prepared to meet the requirements of the U.S. EPA Construction General Permit (CGP) of the NPDES permitting program. The SWPPP addresses project requirements utilizing low impact construction methods and project-specific erosion and sediment control measures. Best Management Practices (BMPs) for erosion control for the various activities will be developed. The BMP specifications to be utilized are taken from The Department of Ecology’s “Stormwater
As part of the SWPPP, a Spill Prevention and Response section will be prepared to address petroleum and hazardous materials handling and management procedures for this project.

Comment: BPA should coordinate with Washington State Department of Ecology (Ecology) and Tribes affected by the project to assure that the state and tribal water quality standards would be met during implementation of the proposed action. Since the project anticipates obtaining a National Pollutant Discharge Elimination System (NPDES) permit for planned construction activities likely to disturb 1 or more acres, the final EIS should include updated information on such permit application process and conditions to protect water quality. [LTR 189, CMT 7]

Response: Coordination efforts with Washington Department of Ecology will be made to ensure that erosion control practices are in place prior to any construction activities if this proposed Project were to move forward. Mitigation measures related to erosion control and water quality standards are discussed in both the Earth section (Section 3.1.3) as well as the Water Resources section (Section 3.3.3). Any Tribal water quality standards will be taken into consideration.

Comment: The [Skamania] Board [of Commissioners] finds [that] in addition to the comment concerning the Scenic Area and the Interstate Highway corridor, [the US Department of] Interior provided specific comments related to purported groundwater issues—issues raised by local citizen neighbor opponents at the NEPA/SEPA comment hearing. Skamania County has regulatory responsibility for groundwater issues, and will work with EFSEC to address the citizen comment. This is not a federal issue. Interior has no authority to insert itself into this uniquely local issue, and its decision to do so demonstrates its lack of regard for Skamania County’s authority: strongly suggesting inappropriate collaboration with Whistling Ridge project opponents. [LTR 197, CMT 8]

Response: Comment acknowledged.

Comment: Well, I don’t want to burst anybody’s bubble of happiness, but where are you all planning on getting the water that’s necessary to produce pumped-storage hydro power? There is no chance on this green Earth that any water is coming out of the Columbia River. There are already too many users and abusers feasting on the Columbia. This is probably a non-starter idea. But, it should have been addressed in the DEIS. BPA’s failure to do so is irresponsible. [LTR 279, CMT 18]

Response: Water to be used during construction of the proposed Project will be purchased from an outside vendor as outlined in Section 1.4.1.5. During operation of the proposed Project,
a well will be drilled on site to provide water primarily for the bathrooms, showers, and kitchen within the Operations and Maintenance building (see Section 3.3.2.1).

**Comment:**  
Watersheds are very important and should be protected from industrial wind farms. [LTR 281, CMT 9]

**Response:**  
Comment acknowledged.

**Comment:**  
No watershed studies have been done for this Project Area, even though the Soil Surveys clearly state that this is a watershed area. [LTR 281, CMT 18]

**Response:**  
Water resources that occur within the proposed Project Area are outlined in Section 3.3 - Water Resources. This section relies on information collected during field surveys which are found in Appendix C - Wildlife Reports (Section C2 - Wetland Delineation Report). Specifically, runoff that occurs within the proposed Project Area is outlined in Section 3.3.1.2 - Stormwater Runoff.

**Comment:**  
[In reference to Section 3.3, Water Resources] - In 2007, Underwood had a really dangerous water situation, as reported in The Columbian newspaper:  
[short article text included] “Underwood water deemed safe to drink” The Columbian State health officials Wednesday lifted a boil-water advisory issued Friday for the Underwood area after tests showed the water is now safe to drink. Major firefighting efforts in the Columbia River Gorge last week drained local water supplies, causing Underwood's water system to lose pressure in some areas. The pressure loss could have allowed contaminants to enter the water, so the state Department of Health and the Skamania County Public Utility District issued the boil-water advisory as a precaution. The Underwood system serves 876 residents. Water supplies have returned to normal, officials said, and excess air has been flushed from the system. Water samples sent for bacterial analysis came back indicating the water is safe. Originally published by KATHIE DURBIN, Columbian staff writer, 9/27/2007. (c) 2007 Columbian. Provided by ProQuest Information and Learning. All rights Reserved. Source: Columbian. The DEIS has no data on the watershed in this area and from which or what type of source, in actuality, the residents get their water. This is a fatal flaw in data gathering and analysis. What would be the cumulative effects, on the water resources that these 876 Underwood residents use, of all the impermeable surfaces—wind turbine pads, substation, maintenance roads, etc. -- that would result from the construction of this proposed wind farm? This is a critical question for fire fighters and the residents. We all know that there will be future fires. What if one of the turbines causes a fire in the woods? Where is the water going to come from to combat this type of fire? Would the Underwood reservoir be depleted thus affecting the residents and their health and safety?[LTR 286, CMT 21]
Response: Please see response to Comment LTR 281, CMT 18 above. The EIS addresses only the water resources currently found within the proposed Project Area and also addresses the future needs and impacts to all water resources found within the proposed Project Area. Any discussion as to how the residents of Underwood, WA, get their water is outside the scope of this EIS. With respect to runoff and cumulative impacts to water resources - runoff from the Project Area are described for the proposed action while in its construction phase, while the proposed Project is in its operational phase, and while the Project is being decommissioned (see Section 3.3.2.1). Cumulative Impacts to water resources are outlined in Section 3.14.3.3 for both surface waters and ground water resources. Lastly, fire fighting and fire prevention plans for the proposed Project are outlined in Section 3.6 - Public Health and Safety. Fire prevention is discussed at length in Section 3.6.1.2 and fire prevention plans are listed under the Mitigation Measures to be implemented within Section 3.6 - Public Health and Safety. The fire prevention plans will be developed in conjunction with the Skamania County Fire Marshall as well as with other appropriate local fire prevention agencies and all plans will be shared with DNR.

Comment: [In reference to Section 3.8.3.1, Proposed Action] - Since there is no watershed data, the proponent cannot say that the project would or would not cause changes in water use. The proponent does NOT know how this project would affect any aquifer's), water tables, or wells, in the area. [LTR 286, CMT 56]

Response: Please see response to Comment LTR 281, CMT 18 above.

Comment: Construction of this facility would create unacceptable impacts on ground water supplies, and contribute to the already high fire hazard. [LTR 283, CMT 15]

Response: Comment acknowledged.

Comment: [In reference to DEIS Section 3.3.1.1, Surface Water] - LIDAR reconnaissance would be useful to determine drainages and streambeds. It could also be used for the geologic survey. Why isn’t LIDAR a requirement for this DEIS? [LTR 286, CMT 22]

Response: BPA follows the rules and guidelines set forth by the Council on Environmental Quality (http://ceq.hss.doe.gov/ceq_regulations/regulations.html) and EFSEC follows the rules and guidelines set forth by the Washington State Legislature (http://apps.leg.wa.gov/RCW/default.aspx?cite=43.21C) for developing their respective environmental documents. The use of LIDAR for analysis of surface waters, drainages, and other landscape-water features is not a requirement for use as a tool of analysis by these agencies (or by any other federal or state agencies for that matter).
Comment: [In reference to DEIS Section 3.3.1.3, Groundwater] - Why weren’t the field investigations done during the rainy season? How does one find perched water tables and if they “may be present at greater depth” shouldn’t they be found since SDS and BPA are proposing to put structures that weigh quite a few tons unto unstable ground that is subject to mass wasting? The groundwater issue needs to be addressed with further field studies and deeper coring. Where is the watershed map for this area? What is the extent of the watershed for this area? The 50+ turbine pads are 50 X 50 feet and this would introduce a large quantity of impermeable surface area to unstable ridges. How would these impermeable surfaces affect water saturation and water flow in the watershed? Is this area included in the Water Resource Inventory Area (WRIA) 29? [LTR 286, CMT 23]

Response: As stated in Section 3.3.1.3, a subsurface investigation conducted in September 2007 that included twelve test pits excavated from 7 to 16 feet in depth did not encounter groundwater in any of the test pits. Because most ground disturbing activities would occur during the drier times of the year, groundwater is not expected to be a construction constraint. Prior to the final siting process, a detailed geotechnical investigation of the specific locations of all wind project elements would be conducted. If this investigation indicates the potential for slope instability at turbine sites or other Project facilities such as access roads (including improvements to West Pit Road), these facilities will be redesigned or relocated to avoid this risk. Figure 3.3-1 was included in the EIS to show the surface water resources in and near the Project Area. Watershed boundaries were not included on this map. The Project Area is located in the Wind/White Salmon Water Resource Inventory Area #29.

Comment: [In reference to DEIS Section 3.3.1.5, Private and Public Water Supplies] - Well, where do these “private water supplies” come from? From perched water tables? Other types of groundwater? Are these wells interconnected? Could the construction and excavation from Whistling Ridge affect these wells? [LTR 286, CMT 24]

Response: Water to be used during construction of the proposed Project will be purchased from an outside vendor as outlined in Section 1.4.1.5. During operation of the proposed Project, a well will be drilled on site to provide water primarily for the bathrooms, showers, and kitchen within the Operations and Maintenance building (see Section 3.3.2.1). Additionally, as outlined on page 3-29 of the DEIS, project water usage is not expected to affect water levels in private wells in the vicinity of the Project.

Comment: [In reference to DEIS Section 3.3.2.1, Proposed Action] - So there is an aquifer. If there is an aquifer then there is groundwater. What is this aquifer, what is its extent? Do the other wells in the area use this aquifer for their water? [LTR 286, CMT 27]

Response: Please see response to Comment LTR 286, CMT 24 above.
Comment: [In reference to DEIS Section 3.3.2.1, Proposed Action] - What are these “mitigation measures” that will be proposed if there are water impacts? What kind of impacts to water resources is SDS anticipating? Why not list these mitigation measures now so that we can all see if they would be adequate? The DEIS should include information on impacts to water resources. [LTR 286, CMT 29]

Response: Mitigation measures for Water Resources are outlined in Section 3.3.3 (and have been available since the release of the DEIS).

Comment: [In reference to DEIS Section 3.3.4, Unavoidable Adverse Impacts] - Now see, this is why this DEIS is so frustrating. Since there is no watershed map and the proponents don’t know whether there is an aquifer or perched water tables or other sources of groundwater, they cannot make such a blatantly inaccurate statement. There is no data in this DEIS that could be used to conclude “negligible to minor impacts to water resources.” The proponents don’t have any way of knowing whether “impacts are localized and the disturbance short term” because they have NOT done a CUMULATIVE IMPACTS ANALYSIS for impacts and effects of this project and all other such projects in the region. [LTR 286, CMT 32]

Response: Figure 3.3-1 lists the drainages that occur nearby and within the Project Area.

Comment: Very little to no analysis is given to the environment affects of increasing the road mileage on the area (DEIS, Page 3-226-3-227). The Final Environmental Impact Statement should include the analysis of sediment from gravel as well as paved road leaching into streams. [LTR 302, CMT 13]

Response: Mitigation measures related to erosion control and their potential effect on water quality standards are discussed in both the Earth section (Section 3.1.3) as well as the Water Resources section (Section 3.3.3).

Comment: The submitted scoping notice identifies the intent of preparing a floodplain and wetland assessment as part of the analysis used in the draft environmental impact statement (DEIS). The assessment should include: An inventory of all wetlands and areas of floodplain in the project area and within the vicinity of the proposal; the environmental values these aquatic features provide to the landscape; what and how the floodplain areas and wetlands will be impacted by the proposal; what environmental values will be lost from these impacts; and mitigation measures to offset the proposed environmental impacts that cannot be avoided. The DEIS should also include an analysis of all other surface water bodies in, and within the vicinity of, the project site. An equivalent documentation of existing environmental values, proposed impacts, and proposed mitigation measures to unavoidable impacts should be outlined in the DEIS as requested for the wetlands and floodplain areas above. [LTR 171, CMT 2]
Response: Wetland inventories were conducted both within the Project Area as well as near the vicinity of the Project Area (see Figures 3.4-2, 3.4-3a and 3.4-3b) and are described in Sections 3.3.1.1 and 3.4.1.3. Floodplain areas were identified in Section 3.3.1.4 and lie outside of the 100-year floodplain for the White Salmon, Little White Salmon, and Columbia Rivers. The description of the environmental values of these water features are described in Section 3.3.1. The impacts to these water features are described in Section 3.3.2. The mitigation measures to be used due to impacts are described in Section 3.3.3. Unavoidable impacts to these described water bodies are seen in Section 3.3.4 and state that construction and operation of the Project would only result in negligible to minor impacts to water resources because the impacts are localized and the disturbance is short-term.

Comment: [In reference to DEIS Section 3.4.2.1, Wetlands, where it was stated that] no wetlands or wetland buffers are located within the project footprint. [This is a] misleading statement. A wetland is included in the project footprint, as it is within the project area borders. This wetland has been and will continue to be impacted if the project is permitted. SDS obtained a permit to harvest timber in the WMZ from DNR. This disturbing activity may have, like most logging operations, damaged the WMZ that could remove silt in runoff from construction activities. Reference – DNR Maps and FPA’s. Remedy - Update and correct this section with the most recent forestry actions that are planned or have occurred. Correct and place this information in DEIS and resubmit for comments. [LTR 178, CMT 108]

Response: There are no wetlands or wetland buffers within any of the Project footprint. This assessment is accurate. There is, however, a wetland classified as “palustrine unconsolidated bottom, semi-permanently flooded, impounded (PUBFh) wetland on the National Wetland Inventory (NWI)” and as a “Category II wetland according to the Washington State Wetland Rating System for Eastern Washington.” This wetland, referred to as a “cedar swamp” is within the Project Area, but it is not within the Project footprint (or more specifically, it is not within the 650' turbine string corridor for turbine string C1-C4.

Comment: [In reference to DEIS Section 3.4.2.1, Wetlands, where it was stated that] no wetlands or wetland buffers are located within the project operation area. [This is a] misleading statement. A wetland is included in the project operation area, as it is within the project area borders and a possible wind impediment. This wetland has been and will continue to be impacted if the project is permitted. SDS obtained a permit to harvest trees in the RMZ of the wetland (or is it called a WMZ?) from DNR (FPA #2704045 and #2704443). Because this wetland is along a road accessing project area from the east, it raises the question of whether the logging [occurred] to improve the road for WRE access or for logging operations or in the words of a long time local "to remove an environmental problem" (sensitive species). Remedy - Update and correct this section with the most recent forestry actions that are planned or have occurred. Correct and place this information in DEIS and resubmit to public for comments. [LTR 178, CMT 109]
Response: Please see response to Comment LTR 178, CMT 108 above. The focus of this EIS is related to impacts from the construction, operation, and decommissioning of the proposed wind facility and its related interconnection transmission request. The focus of this EIS does not take into consideration the logging operations in which the applicant is currently engaged. There is mention of the applicants current logging activities (see Sections 1.4.2 and 2.2, and in multiple areas within Chapter 3), but they are outside the scope of this EIS.

Comment: [In reference to the statement that] “roadway improvements to the County or private logging roads are not expected to affect wetlands. This information was confirmed through field investigations performed in May and July 2009.” - This Report is not cited as existing in Appendix. Remedy - include this report in DEIS and resubmit to public for comments. [LTR 178, CMT 110]

Response: Both the DEIS and associated appendices were released to the public for comment on May 25, 2010. The appropriate mitigation measures will be in place for any road improvements to ensure little-to-no erosion run-off and also to protect any water resources in the vicinity of these road improvements. See Section 3.3.3 for a listing of all mitigation measures to be used related to water resources.

---

G.3.4 BIOLOGICAL RESOURCES

Comment: This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because this project is proposed along a forested ridgeline in the foothills of the Cascade Mountains. The project would permanently disturb large areas of forested habitat and result in direct and indirect impacts to multiple wildlife species through habitat loss and displacement, direct collisions with turbine blades, and other factors. The potentially affected listed and sensitive species include northern spotted owl, western gray squirrel, northern goshawk, several species of bats, multiple migratory bird species, mule deer, black-tailed deer, and elk. In addition, locating 426-foot-tall turbines on the ridge line of the Columbia River Gorge would degrade the scenic value of the Gorge. [LTR 2, CMT 2]

Response: Comment acknowledged.

Comment: I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood area, along the Skamania and Klickitat county line. The proposed project would cause significant positive impacts to sensitive wildlife and plant habitat. [LTR 3, CMT 1]
Response: Comment acknowledged.

Comment: This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because this project is proposed along a forested ridgeline in the foothills of the Cascade Mountains. Response: Comment acknowledged.

Comment: I have reviewed the wildlife baseline studies and I have visited the site. There are no significant. Sensitive wildlife and plant habitat areas associated with this project area. [LTR 28, CMT 2]

Response: Comment acknowledged.

Comment: There is no evidence that the installation and operations of the proposed facility will have any significant impacts on sensitive or special status animal or plant species. The data and analysis by qualified third parties indicates that no significant impact will occur. The Whistling Ridge Wind Farm is also outside of the Columbia River Gorge Natural Scenic Area. [LTR 28, CMT 5]

Response: Comment acknowledged.
Comment:  There are no sensitive species and no sensitive habitat in or adjacent to the lands in question, so the impact of the wind farm will be insignificant. [LTR 31, CMT 2]

Response:  Comment acknowledged.

Comment:  They harm wild life. [LTR 32, CMT 2]

Response:  Comment acknowledged.

Comment:  This proposal is not likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, even though this project is proposed along a forested ridgeline in the foothills of the Cascade Mountains. Whistling Ridge has been studied for seven years and found to pose no wildlife impacts. [LTR 34, CMT 2]

Response:  Comment acknowledged.

Comment:  I was happy to learn that the US Department of Fish and Wildlife has found that there would be no significant impact on wildlife as a result of this project. [LTR 35, CMT 3]

Response:  Comment acknowledged.

Comment:  The DEIS provides no evidence to substantiate the applicant's assertion that the proposed Whistling Ridge wind project will not cause mortality to birds and bats in sufficient quantities to affect population viability. The analysis does not include any reasonable estimates of current population levels of sensitive species, nor of the threshold population levels required to maintain viability. [LTR 36, CMT 3]

Response:  The Wildlife Society, in a landmark publication on wind energy and wildlife, concluded that fatalities of passerines from wind turbine strikes generally are not significant at the population level (Arnett et al. 2007). In addition, the National Academy of Sciences (NAS 2008) recent review of wind energy impacts on birds came to the following conclusion: “At the current level of wind-energy development (approximately 11,600 MW of installed capacity in the United States at the end of 2006, including the older California turbines), the committee sees no evidence that fatalities caused by wind turbines result in measurable demographic changes to bird populations in the United States, with the possible exception of raptor fatalities in the Altamont Pass area.” The available information suggests that the Project would be unlikely to have population impacts on birds. Additionally, the revised report “Analysis of Cumulative Impacts on Avian, Bat and Habitat Associated with Wind Energy Development in the Columbia
Plateau Ecoregion of Eastern Washington and Oregon” (WEST 2010) prepared for Klickitat County does not suggest the possibility of cumulative population impacts on birds.

Comment: An independent study of Big Horn’s monitoring results written by Dr. Smallwood concluded that raptor fatalities are up to 16 times higher than predicted prior to construction? Big Horn also kills twice as many bats as anticipated, according to fatality monitoring reports. Monitoring studies at other wind projects in Klickitat County are not yet completed, but the preliminary results from those projects suggest even higher fatality rates. The above-cited independent scientific analysis based on the results from Big Horn (the only project in Klickitat County where fatality monitoring has been completed) reported a conservative estimate of 243 raptor fatalities annually in Klickitat County. That estimate of 243 raptor fatalities is for a level of development that does not exceed 1,000 megawatts. At its current rate of wind development, Klickitat County is likely to reach a level of 2,000 megawatts or more within the next year or so. For raptors in Klickitat County, these numbers are rapidly approaching population-level impacts. “There is probably no other human source of mortality that comes close to these levels,” writes Dr. Smallwood. The DEIS underestimates potential impacts on northern spotted owls and other avian species. The proposed project falls within critical habitat for the northern spotted owl, a species that is not only endangered but has continued to decline since the adoption of the Washington Department of Natural Resources’ Habitat Conservation Plan for the species. This species has continued to decline on federal lands, which makes the state’s HCP more important than ever. There are only an estimated 500 northern spotted owl pairs remaining in all of Washington State. Even as the state’s Habitat Conservation Plan is failing miserably, the applicant is proposing to undermine that plan by allowing commercial-scale energy development within a Spotted Owl Special Emphasis Area. A commercial wind energy project is not appropriate for habitat that is designated as a nesting, roosting and foraging area for a federally endangered species. In materials distributed to the public prior to the mid-June 2010 hearings, SDS Lumber writes: “After years of timber harvest, there's no suitable habitat for the bird.” It is ironic that the applicant is pointing the finger at its own destructive timber practices to justify further risk to northern spotted owls. Regardless of whether spotted owls are currently nesting on or near this property, as they did in recent history, this area is designated as prime potential habitat for the species. The fact that Washington’s Habitat Conservation Plan for spotted owls is not increasing the numbers of reproductive pairs makes it all the more important to restore this species’ habitat—not to damage it even further. The Environmental Impact Statement commissioned by Klickitat County for its Energy Overlay Zone stated (on page 2-15 of the Final EIS) that “forested areas host higher concentrations of owl and other sensitive species habitats.” The EIS recommended that areas with high concentrations of forested habitats be excluded from the Energy Overlay Zone because of their “higher potential for use by sensitive species and avian species likely to be impacted by wind turbines.” This sensitive forested habitat is exactly what is being proposed for development at Whistling Ridge. Spotted owls are not the only species likely to be significantly impacted by the proposal. Klickitat County’s Energy Overlay EIS also found high use of forested habitats by other raptors. The SDS map for the proposed project shows ridge-top locations for turbines, and these are typically the worst possible locations from an avian perspective—i.e., likely to result in the highest number of bird collisions. 6. The DEIS fails to assess compliance with state and federal laws protecting bald eagles, golden eagles, migratory birds, and endangered species. There are reports of bald eagles
and bald eagle nests at the proposed wind site. Yet there is no evidence that the proposed project will be in compliance with the state's Bald Eagle Protection Act, RCW chapter 77.12, and regulations associated with this act. Nor is there any evidence that the proposed project will be in compliance with the federal Bald and Golden Eagle Protection Act, 16 USC § 668-668(d). This act prohibits any person, association, partnership or corporation from taking a bald or golden eagle at any time or by any manner without a permit. A permit may be issued only if the take would be compatible with the preservation of the species. There is no evidence in the DEIS that the proposed project will be in compliance with the federal Migratory Bird Treaty Act (MBTA), 16 USC §§ 703-712. The MBTA requires that the U.S. Fish & Wildlife Service take enforcement against “any person, association, partnership or corporation” that “by any means or in any manner” pursues, hunts, takes, captures, kills, or attempts to take, capture or kill a migratory bird or any part, nest or eggs of any migratory bird. Under the MBTA, a corporation may take or kill a migratory bird only if the U.S. Fish & Wildlife Service determines that the take or kill is compatible with migratory bird treaties. This determination must include an evaluation of the bird's species abundance and distribution, as well as its migratory and breeding habits. The killing of a single migratory bird is sufficient to create criminal liability, and does not need to be intentional. There is no evidence in the DEIS that the proposed project will be in compliance with the federal Endangered Species Act (ESA) of 1973, 16 USC §§ 1531-1544. Under the ESA, “take” is defined as “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct.” Section 9 of the ESA prohibits any actions that would “take” an endangered species, as well as actions that would cause an act constituting a “take.” The Ninth Circuit has held that “a habitat modification which significantly impairs the breeding and sheltering of a protected species amounts to ‘harm’ under the ESA.” It seems quite possible that the proposed Whistling Ridge wind project may kill a bald eagle, a migratory bird, or an endangered species. The DEIS must evaluate the likelihood of each of these possibilities, and whether Incidental Take Permits are required from the U.S. Fish & Wildlife Service. A recent court ruling in West Virginia has made it clear that such permits are required under federal law when a wind project is likely to kill any individual animals protected by the Endangered Species Act. [LTR 36, CMT 8]

Response: The baseline avian use study was conducted in compliance with the Washington Department of Fish and Wildlife (WDFW) Wind Energy Guidelines (WDFW 2009). There is a growing body of data available to compare pre-construction avian use estimates with post-construction mortality, and the pre-construction use estimates show a positive correlation with avian mortality. The methods used to show a disparity between pre-construction estimates and elevated post-construction mortality are being contested as not accurate. The proposed Whistling Ridge Project is located in Skamania Co., rather than Klickitat Co., so estimates of wind development for Klickitat Co. were not considered. The American Wind Energy Association reviewed human-caused sources of bird mortality in 2001, and determined that only 0.01 to 0.02 percent of the mortality was from wind developments. As noted in Section 3.4.2.1 (on DEIS page 3-75), the Project has been sited to avoid habitat areas deemed critical to the northern spotted owl or essential to its recovery. Surveys conducted pursuant to the USFWS protocol indicate that spotted owls are not present in or near the Project Area. No bald eagle nests occur on site and eagle use of the Project Area was determined to be extremely low. Avian and raptor use was also relatively low; therefore, no significant impacts to eagles or migratory birds are anticipated. Section 4.5 of the EIS addresses compliance with the Migratory Bird Treaty Act. Section 4.7 addresses compliance with the Bald Eagle Protection Act. Section 4.7
has been corrected to revise the last sentence to read: “The Project would not involve intentional acts or acts in wanton disregard of bald or golden eagles. Any accidental injuries or deaths would be subject to Federal law.” The EIS, in Section 3.4, evaluates the potential for harm to a bald eagle, migratory bird, or an endangered species. BPA prepared a Biological Assessment (dated June 8, 2010) and submitted it to USFWS for informal consultation. In a letter to BPA dated July 19, 2010, USFWS concurred with BPA’s conclusion that the Project “may affect, but is not likely to adversely affect, the northern spotted owl, a threatened species.” The northern spotted owl is the only listed or threatened species present or with critical habitat in the vicinity of the Project Area. Please see response to Comments LTR 173, CMT 1 to LTR 173, CMT 4 - the USFWS Section 7(a) consultation concurrence for this project.

Comment: This proposal NOT is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because this project is proposed along an actively forested ridgeline in the foothills of the Cascade Mountains. [LTR 40, CMT 2]

Response: Comment acknowledged.

Comment: Collisions with turbine blades are a minor concern compared to the impacts of fossil [fuel] generation. [LTR 40, CMT 4]

Response: Comment acknowledged.

Comment: While I am a supporter of renewable energy, all the environmental choices we make need to be careful ones, considering all impacts. The Whistling Ridge Energy Project, along the Skamania and Klickitat county line is a mix of positive and negative impacts - the negative effects on wildlife and on the environmental well-being of the Gorge outweigh the benefits. I am aware that the potentially affected listed and sensitive species include northern spotted owl, western gray squirrel, northern goshawk, several species of bats, multiple migratory bird species, mule deer, black-tailed deer, and elk. I sincerely hope the decision-makers involved will listen to reason and choose alternatives, preserving what undisturbed areas we have left! [LTR 42, CMT 1]

Response: Comment acknowledged.

Comment: Death to thousands of various wild animals (birds and mammals--especially our best friends, BATS/mosquito mowers, which are abundant in the fecund Cascades). [LTR 49, CMT 2]
Response: Comment acknowledged.

Comment: Just say "NO" to: Death and malaise to thousands of beautiful and beneficial animals. [LTR 49, CMT 6]

Response: Comment acknowledged.

Comment: This proposal is not likely to have any different or greater wildlife impacts than any other wind energy facility proposed in the State of Washington. The project will not permanently disturb any areas of forested habitat and will not result in direct or indirect impacts to the multiple wildlife species. None of the listed or sensitive species including the northern spotted owl, western gray squirrel, northern goshawk, several species of bats, multiple migratory bird species, mule deer, black-tailed deer, or elk will suffer detrimental effects from this project. I support renewable energy, and I support industrial-scale wind energy development wherever it can help us become energy self sufficient. [LTR 52, CMT 2]

Response: Comment acknowledged.

Comment: This proposal is unlikely to have any different and greater wildlife impact than any other wind energy facility proposed in the State of Washington, perhaps even less because this project is proposed along an already cleared for utility access low ridgeline in the foothills of the Cascade Mountains. [LTR 53, CMT 2]

Response: Comment acknowledged.

Comment: The wind turbines are also detrimental to the birds, big horn sheep and wild life and the endangered species in the area. [LTR 55, CMT 2]

Response: Comment acknowledged.

Comment: This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because this project is proposed along a forested ridgeline in the foothills of the Cascade Mountains. The project would permanently disturb large areas of forested habitat and result in direct and indirect impacts to multiple wildlife species through habitat loss and displacement, direct collisions with turbine blades, and other factors. The potentially affected listed and sensitive species include northern...
spotted owl, western gray squirrel, northern goshawk, several species of bats, multiple migratory bird species, mule deer, black-tailed deer, and elk. [LTR 57, CMT 3]

Response: Comment acknowledged.

Comment: I am a renewable energy enthusiast yet I feel I need to speak out about this project. In eastern Oregon there are prolific wind generators located in some key areas of strong wind. All that I have seen so far, are located in grassland areas with virtually no trees nearby. This locating factor reduces the possibility of damage to wildlife because most of the wildlife is lower flying, if at all, having little habitat from 100 feet up. However, to locate 50 wind generators in the middle of a forested area really exposes a great deal of habitat to almost 6000 feet of turbulent rotors, which they will not survive. Please do not allow the dollar signs and the green speak to move us one step forward yet 3 steps back. [LTR 59, CMT 1]

Response: Comment acknowledged.

Comment: More recent studies on bat and raptor deaths caused by wind turbines indicate a significantly higher number than expected. Klickitas County has recently begun a new study because many more deaths were occurring than promised by the boiler plate information in their EIS. Please update your study to consider recent results. [LTR 60, CMT 8]

Response: The revised report “Analysis of Cumulative Impacts on Avian, Bat and Habitat Associated with Wind Energy Development in the Columbia Plateau Ecoregion of Eastern Washington and Oregon” (WEST 2010) prepared for Klickitat County has been included as an appendix in the FEIS. A revised cumulative impacts analysis that takes into consideration wind energy development within forested habitats of western WA has been added to Section 3.14.3.5 of the EIS.

Comment: There does not seem to be mention or analysis of that land being designated as “Deer and Elk Winter Range”? I was unable to get a map from WDFW in this short time, but I do know that the land immediately south of the project is designated winter range preserve. If this project is or is not in the preserve, what would be the impacts to elk and deer movement, how will they react to the “strings” of turbines, operational noise, construction, etc? If you believe that this wildlife will simply “go around”, what is the impact and how will the applicant mitigate the impact to the surrounding communities now in the path of ranging wildlife? What would be the impact to the surrounding communities when the predators (e.g. cougars) follow the new path, and how will we be protected? [LTR 60, CMT 9]

Response: Information on the winter range for deer and elk was presented in Section 3.4.1.6 (on page 3-69 of the DEIS). As stated, WDFW Priority Habitat for mule deer and black-tailed deer (winter range) are present east of Underwood Mountain (east of the Project Area), and
Columbia black-tail deer (winter range) is present west, north and south of the Project Area. The only WDFW Priority Habitat that exists in the Project Area is winter range for elk. Potential impacts during construction were presented in Section 3.4.2.1 (on page 3-76 of the DEIS). As noted on DEIS page 3-81, additional coordination with WDFW is on-going regarding elk habitat.

**Comment:** I've spent several winters in desert hot springs/palm springs area and not once have I seen any bird kill from the wind turbine windfarms. [LTR 63, CMT 1]

**Response:** Comment acknowledged.

**Comment:** This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat[s]. [LTR 66, CMT 2]

**Response:** Comment acknowledged.

**Comment:** In one area it states that this project has to be defined as an “integrated whole” to be worthwhile yet in the design/mitigation measure under Biological Resources that “micrositing of turbines and associated facilities would allow any sensitive resources discovered during construction to be avoided.” You can’t have it both ways. [LTR 74, CMT 3]

**Response:** The EIS considers numerous protected resources, and considers them as an integrated whole in terms of identifying any resource (or resources) that may require additional protection through macro- and micro-siting turbine strings and individual turbines.

**Comment:** This EIS is woefully insufficient in its evaluations of wildlife. It does a poor job of covering bat evaluations, lacks significant bird/bat dispersal data and has no mention of large animal. It is so bold as to state, “For potential impacts to big game species (deer and elk), coordination with WDFW will occur if appropriate.” It is a known wintering ground for Elk. Also what about cougar, bobcat, coyotes and all the other game? It states that it will “Convene a Technical Advisory Committee to evaluate mitigation and monitoring programs for impacts to wildlife and habitat” - why is this not already in place? [LTR 74, CMT 8]

**Response:** Large mammal effects were described in the DEIS on page 3-76. Three years of bat studies were conducted at the Whistling Ridge site, likely more than any other proposed wind project in the country. Bat mortality will be monitored post-construction, and, if warranted, turbine curtailment during low wind speed nights is known to dramatically reduce bat fatalities and would be implemented at the site to reduce fatalities.
Comment:  Birds mortality! Let ['s] close the airport in Portland! [LTR 75, CMT 4]

Response:  Comment acknowledged.

Comment:  In view of the fact that no studies have been conducted in the US that determine what effect wind turbines have upon forest-dwelling species of wildlife, it is inappropriate and misleading to repeatedly state that “No impacts are anticipated…” Frequent statements of conclusion appear throughout the document; some are nebulous, speculative, inaccurate or contradict the material provided in the previous text or appendices and add to the appearance of bias. On [DEIS] page 3-77, it is confidently stated that “Operation of the project would result in no further impacts to habitats on the project site” despite a statement on [DEIS] page 3-81 that “Because data on impacts to big game as a result of wind project operations is limited, it is difficult to predict the impact of the proposed project on wildlife using priority habitats on the proposed project site.” (“Additional coordination with WDFW is ongoing, and would continue to address this resource.”) [LTR 76, CMT 3]

Response:  The statement on DEIS page 3-77 refers to “no further impacts” beyond those described during the construction phase, while the statement on DEIS page 3-81 indicates the uncertainty regarding the operational effect on big game.

NOTE:  Chapter 3 of the EIS (Affected Environment, Impacts, and Mitigation) is organized so that it describes the Impacts during the construction-, operation-, and project decommissioning-phases for the Proposed Action. Impacts under these different phases of the Proposed Action differ in nature and to present them this way allows the reader to know what impacts are expected during each phase.

Comment:  The Columbia River flyway could be considered a cultural resource for the avian species. It has likely existed for a longer time than humans have been here and constitutes a known route for both north-south and east-west migrating birds. It is inconceivable that a project that is known to kill birds could be approved for an area located within the flyway. Larger turbine blades and consequent slower rotation speeds have been reported to minimize bird fatalities, but the fact that Columbia River is the major western flyway in the United States negates this improvement since denser concentrations of birds would be present during migration flights. The rotation speeds mentioned in the document stipulated a wide range and was indicative that the authors were not aware that rotation speed guidelines purporting to offer some protection from bird strikes are available. [LTR 76, CMT 8]

Response:  Based on the avian point count data, bird use in the Project Area is considered too low to identify the site as a flyway or concentrated migration route. Birds are migrating through the Project Area, but not using it as a primary route.
Comment: The flyer [sent out by the project proponent] further asserts that there will be no “harm” to wildlife populations. This also is a hoax. The raptor mortality from wind energy projects developed in Klickitat county is ten times what the EIS predicted [as reported by Kathy Durbin in The Columbian - “First Golden Eagle killed by Wind Turbines in WA State”). [LTR 77, CMT 4]

Response: Comment acknowledged.

Comment: The draft [EIS] also does not state, as it should, that this project would be the first such project allowed on Pacific Northwest forest lands. Moreover, the draft should recognize that no comprehensive studies have been made concerning effects of wind turbines upon Pacific Northwest forest dwelling wildlife. [LTR 79, CMT 6]

Response: Both the avian and bat fatality studies in the DEIS appendices acknowledged that no wind energy facilities have been constructed in Pacific Northwest coniferous forests. Because the Whistling Ridge site is in an even aged, relatively young forest managed for timber production, wildlife habitat on the site is already greatly compromised.

Comment: Potential impacts on mammals other than draft-mentioned bats and a single squirrel species should be described in the EIS. What animals are present in what relative numbers, and which are most likely to be driven from or avoid the area because of the turbines? [LTR 79, CMT 7]

Response: Section 3.4.1.6 (on page 3-69 of the DEIS) described the large mammals that have the potential to occur within the Project Area, including cougar, bobcat, coyote, and black bear. The site is within the winter range of elk. Douglas squirrels were recorded during surveys for western gray squirrel. Potential construction impacts were discussed in Section 3.4.2.1 (on DEIS page 3-76).

Comment: Estimates of expected turbine-caused avian and bat mortalities should be included by utilizing available information from studies at existing wind farm projects. Such estimates would perhaps be difficult for those bird and bat species that prefer forest habitats. But most bird species that frequent Whistling Ridge (87 species, including the bald eagle and five others of "Special Concern", have been recorded there) are also found around wind farms where mortality studies have already been made. To simply state, as the draft now does, that the turbines would "not affect viability" of bird and bat populations "in the region" is quite inadequate. Cumulative impact data, rather than unfounded beliefs, are necessary in making decisions of the magnitude that this proposal encompasses. [LTR 79, CMT 8]

Response: Pre-construction use data for birds was compared with that from eleven other wind developments where post-construction mortality data was available. Use estimates
compared with these other wind developments suggest the mortality from the proposed Project would occur at similar levels (moderate). Bat monitoring data was difficult to use for predicting mortality, because the pattern of use varied compared with the use pattern from the other sites. Data from numerous wind projects were used to predict avian fatality rates at Whistling Ridge. A revised cumulative impacts analysis, which takes into consideration proposed wind energy development in coniferous forests of western Washington and Oregon, has been added to Section 3.14.3.5, under the subheading of Bird and Bat Species.

Comment: Numerous wildlife species, not just those threatened or endangered, rely of forest habitats. Bird mortality from wind turbines is fairly well documented, but most such studies have focused on turbines located outside of forest areas. Other wildlife concerns are associated with the SDS proposal; these concerns include seasonal use patterns, travel corridors, habitat alteration or removal, soil loss and associated stream sedimentation, and area abandonment by wildlife due to turbine noise. Many animals, with hearing more acute than ours, can be detrimentally affected by noise. [LTR 79, CMT 17]

Response: Comment acknowledged.

Comment: [Excerpts from] The Oregonian, June 11, 2010; and, “Birds vs. the wind farms,” by Hal Bernton, The Olympian, June 08, 2010: “Based on that information, the windpower turbines currently operating in Oregon and Washington kill more than 6500 birds and more than 3000 bats annually.” [LTR 82, CMT 9]

Response: Comment acknowledged.

Comment: This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because this project is proposed along a forested ridgeline in the foothills of the Cascade Mountains. The project would permanently disturb large areas of forested habitat and result in direct and indirect impacts to multiple wildlife species through habitat loss and displacement, direct collisions with turbine blades, and other factors. The potentially affected listed and sensitive species include northern spotted owl, western gray squirrel, northern goshawk, several species of bats, multiple migratory bird species, mule deer, black-tailed deer, and elk. I am especially concerned about the impact on spotted owls, as recent studies have shown their numbers continue to decrease steadily, even dramatically in some areas. Any development that might disturb their habitat must be closely, closely scrutinized. [LTR 87, CMT 2]

Response: Comment acknowledged.
Comment: It [the Project] will be an eyesore and kill many birds. Bald Eagles inhabit the area. [LTR 92, CMT 3]

Response: Comment acknowledged.

Comment: The Washington Department of Fish and Wildlife (WDFW) has reviewed the above reference document and offers the following comments at this time. Other comments may be offered as the project progresses. Overall, the Preliminary DEIS is consistent with the 2009 WDFW Wind Power Guidelines, including early and regular consultation, as well as avian and bat studies, habitat characterization, and impact analysis. [LTR 94, CMT 1]

Response: Comment acknowledged.

Comment: We support the two-year minimum post-construction avian mortality study, as well as the development of a Technical Advisory Committee (TAC) WDFW is in general agreement with the proposed commercial forestry operations within the vicinity of each turbine as described in [DEIS] Section 3.0 (“turbine timber buffer”) and would like to offer the following interpretation. According to [DEIS] Section 3.0, “Vegetation surrounding each turbine would be managed according to the following specifications: A circular area extending 50 feet from each turbine tower base would be harvested and graveled. From 50 feet to 150 feet from the base of the turbine towers, tree heights would be limited to 15 feet above the elevation of the base of the turbine. From 150 feet to 500 feet from the base of the turbine towers, tree height would be limited to 50 feet above the turbine base within an area formed by it 90 degree arc centered on the ordinary downwind direction.” From this, we conclude that within a diameter of 100 to 300 feet surrounding each turbine, tree heights would be limited to 15 feet, and from a diameter of 300 to 500 feet, tree heights would be limited to 50 feet, but only within a 90-degree arc on either side of the turbine aligned with the direction of the prevailing wind. The other 90-degree arc on either side of the turbine perpendicular with the direction of the prevailing wind will essentially be unchanged habitat (i.e. existing commercial forest). We are interested in how this type of habitat and commercial forest management in the immediate vicinity of operating wind turbines will or will not affect the avian and bat mortality. We look forward to working with Whistling Ridge through the TAC to address this issue and cooperatively develop management strategies, if needed, to reduce avian and bat mortality. Thank you for the opportunity to review the Preliminary DEIS and offer these comments. [LTR 94, CMT 3]

Response: Comments acknowledged. The interpretation in the comment is correct with the exception that within the diameter from 300 feet to 1000 feet (not 500 feet) heights would be limited to 50 feet within a 90-degree arc with the direction of the prevailing wind. See Figure 2-4 in the DEIS.
Comment: As a key participant in these processes, it is our view that the most important element of good wind energy facility siting that minimizes impacts to wildlife and habitat is the early, active and regular consultation with the interested public and with wildlife agencies, including the development of specific protocols to evaluate potential impacts. As noted in a January 19, 2010 letter from WDFW to the Whistling Ridge Energy Project permitting consultant (enclosed), the wildlife data and information supporting the agency review draft of the DEIS “is consistent with the 2009 WDFW Wind Power Guidelines, including early and regular consultation, as well as avian and bat studies; habitat characterization, and impact analysis.” Under the 2009 Wind Power Guidelines, for commercial forestlands, consultation with WDFW is the principal measure to address habitat and wildlife concerns. Whistling Ridge Energy’s early and regular consultation with WDFW, and its use of study protocols and analyses particularly tailored to commercial forestlands, satisfies the spirit and letter of the Guidelines. The Whistling Ridge Energy Project has undergone consistent and regular wildlife and habitat studies for multiple seasons and multiple years, beginning as early as 2003. Avian data has been secured over multiple years and in every season of the year. Whistling Ridge has also completed three years of season-specific analysis of bat populations, demonstrating a commitment to wildlife agency review of data concerning impacts to bats. [LTR 94, CMT 7]

Response: Comment acknowledged.

Comment: The wildlife habitat in the area will change, but the habitat itself will not be “lost.” Some animals will move out while others will move into the area. In this case, change might be good, or at least neutral. [LTR 96, CMT 4]

Response: Comment acknowledged.

Comment: I have been to meetings and listened to the talk about how safe for birds these mills are. The [N]ative Americans told us that they could not imagine how a bird could fly into these blades. About 2 weeks later, front page of the Oregonian, Golden eagle killed by wind turbines at Goodnoe Hills. How many Golden Eagles are there in the gorge? At least one is dead. We were told that up to 7000 bats would be killed if the Whistling Ridge project goes in. How many hawks and eagles will die because of this? [LTR 102, CMT 5]

Response: The bat data collected at met towers in 2009 in the area most likely to be developed for wind energy does not suggest bat mortality would be excessive at this site. The estimated raptor mortality rate is 0 to 0.25/MW/year.

Comment: The effect of a wind farm on bird and wildlife populations is negative. Turbines Kill!! [LTR 104, CMT 3]

Response: Comment acknowledged.
Comment:  [...] killing of birds and wildlife [...] [LTR 118, CMT 3]
Response:  Comment acknowledged.

Comment:  There are many items that should be considered from an environmental and ecosystem perspective regarding a large project like this. All projects like this have an “environmental cost” and although it may not appear to affect our community directly, it does affect the earth; ultimately we are all reliant on the environmental resources of the earth to keep us and all other living creatures alive. In particular, we are concerned that, due to this Project's location in a forest ecosystem, far more wildlife will be negatively affected or harmed than if it were located in a wheat field or open plain environment. [LTR 119, CMT 6]
Response:  Comment acknowledged.

Comment:  This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because this project is proposed along a forested ridgeline in the foothills of the Cascade Mountains. The project would permanently disturb large areas of forested habitat and result in direct and indirect impacts to multiple wildlife species through habitat loss and displacement, direct collisions with turbine blades, and other factors. The potentially affected listed and sensitive species include northern spotted owl, western gray squirrel, northern goshawk, several species of bats, multiple migratory bird species, mule deer, black-tailed deer, and elk. [LTR 121, CMT 4]
Response:  Comment acknowledged.

Comment:  More recent studies on bat and raptor deaths caused by wind turbines indicate a significantly higher number than expected. Klickitat County has recently begun a new study because many more deaths were occurring than promised by the boiler plate information in their EIS. Please update your study to consider recent results. Eliminating the A1-A7 turbines would significantly reduce the risk of bat and raptor deaths as the turbines closest to the flyway are eliminated. [LTR 124, CMT 7]
Response:  There is a growing body of data available to compare pre-construction avian use estimates with post-construction mortality, and the pre-construction use estimates show a positive correlation with avian mortality. The methods used to show a disparity between pre-construction estimates and elevated post-construction mortality are being contested as not accurate. Based on the avian point count data, bird use in the Project Area is considered too low to identify the site as a flyway or concentrated migration route. Birds are migrating through the Project Area, but not using it as a primary route.
Comment: The land immediately south of the A1-A7 turbines project is designated winter range preserve. Eliminating the A1-A7 turbines eliminates a major impact to elk and deer movement in their designated winter range. [LTR 124, CMT 8]

Response: As noted in Section 3.4.1.6 (on DEIS page 3-69) of the, only elk winter range is present within the Project Area and it is located throughout the Project Area, not just in the location of the A-string.

Comment: This proposal is likely to cause significant negative impacts to sensitive wildlife and plant habitat. [LTR 127, CMT 2]

Response: Comment acknowledged.

Comment: I've been told also that wildlife will be greatly impacted in this location. [LTR 130, CMT 2]

Response: Comment acknowledged.

Comment: The Draft EIS found; [bulleted item] - No significant impact on wildlife or bird populations. [LTR 140, CMT 2]

Response: Comment acknowledged.

Comment: A recent bird study in Klickitat County is not even mentioned in the EIS. Please, do not rubber stamp this project! [LTR 142, CMT 3]

Response: The best available data refers specifically and only to the cumulative impacts analysis for the Columbia Plateau Ecoregion. A revised cumulative impacts analysis that considers proposed wind energy development in forested habitats of western WA has been added to Section 3.14.3.5 of the FEIS.

Comment: It is indeed sad that wind turbines impact individual birds. As a birder and long time volunteer for a raptor rehabilitation center, I'm the last person who would want to see birds die. But they are dying by the thousands---tens of thousands----across the globe because of climate change's impact on habitat. [LTR 156, CMT 3]

Response: Comment acknowledged.
Comment: The WEST report prepared for the Klickitat County Planning Department is not applicable to the proposed Whistling Ridge Energy Project, and cannot be relied upon to evaluate cumulative impacts. The report prepared by Western EcoSystems Technology, Inc. (WEST) purports to be a cumulative impacts analysis for Klickitat County. [REFERENCE: Avian, Bat and Habitat Cumulative Impacts Associated with Wind Energy Development in the Columbia Plateau Ecoregion of Eastern Washington and Oregon, Prepared for Klickitat County Planning Department by Gregory D. Johnson and Wallace P. Erickson, Western EcoSystems Technology, Inc., February 2010] Unfortunately, this report sheds little light on the cumulative impacts of wind power development on wildlife in Klickitat County, and it is even less relevant to a project proposed for Skamania County. As the WEST report's title suggests, the Columbia Plateau Ecoregion is located in eastern Washington and Oregon, which have completely different plant and animal communities than the western Washington site proposed for the Whistling Ridge wind project. All of the projects evaluated in the WEST report are located in arid and un-forested lands, whereas Whistling Ridge is located in a coniferous forest that receives much more precipitation and has a much different plant and animal population. Impacts of wind projects on birds and bats are extremely site-specific, and because of that the WEST study has little applicability to the Whistling Ridge proposal. It is no more applicable than studies from the Altamont Pass Wind Resources Area in California, where significant population-level impacts on birds have been documented; or from the forested Mountaineer wind project in Appalachia, where significant population-level impacts on bats have been documented. The WEST report contains fatality monitoring data from 12 projects around the Columbia Plateau Ecoregion. Only one of those projects, Big Horn, is actually located in Klickitat County—and the results from Big Horn show much higher raptor fatality rates than anywhere else in the Pacific Northwest. In other words, the WEST report underestimates the impacts of wind projects in Klickitat County by merging the Big Horn data with results from less lethal projects elsewhere in the region. The WEST report also looked at 24 projects in the Pacific Northwest for which preconstruction estimates of avian use are available. Here too, the results from Klickitat County show a much higher likelihood of avian impacts than elsewhere in the region. Of the 24 projects evaluated in the report, the seven projects located in Klickitat County had much higher estimated use by both raptors and by birds of all types. For example, the highest raptor use estimated anywhere in our region is at the Linden Ranch in Klickitat County. Raptor use there is estimated to be 2.5 times the average for the Columbia Plateau ecoregion. In other words, the WEST report does not give an accurate picture of cumulative impacts from expanding wind power here in Klickitat County, much less any indications of cumulative impacts to be expected in Skamania County. To the contrary, the WEST report uses data from projects in other parts of Oregon and eastern Washington to underestimate how many birds—especially raptors—are likely to be killed here. The WEST report has another fundamental flaw. To arrive at a prediction of cumulative fatalities, the report's authors averaged existing fatalities in the region and then compared those averages with estimates of regional population size based on breeding bird surveys provided by the Partners in Flight North American Landbird Conservation Plan. However, the Partners in Flight estimates include relatively large standard errors, and are not accurate enough to serve as reliable population indicators. The estimates used in the WEST report were designed for detecting long-term population trends but not for estimating population size. As Dr. K. Shawn Smallwood, an ecologist who is one of the nation's leading experts on the interactions between wildlife and wind turbines, points out in a review of the WEST report, the estimates from Partners in Flight are “unsuitable for the use that Johnson and Erickson made of them.” [REFERENCE: Review of Cumulative Impacts Analysis of Wind
Energy Expansion on the Columbia Plateau, K. Shawn Smallwood, May 18, 2010]. Other researchers have pointed out this flaw but WEST continues to rely on these unsuitable estimates. Smallwood further writes: “No studies or monitoring programs have been designed or implemented in the US to document wind energy-related population declines of any bird species. Most fatality monitoring programs have been much too brief to document declines, lasting one or two years. All monitoring programs have been too crude to document declines, and the majority of post-construction studies have not been designed to estimate population size of any bird species. Therefore, Johnson and Erickson's statement about wind energy impacts was misleading.” There is no peer-reviewed science in the DEIS submitted by the applicant. Instead the applicant relies on WEST, a wind industry contractor whose work has not been independently reviewed. [LTR 161, CMT 5]

Response: The DEIS recognized that the WEST report was developed for the more arid shrub-steppe lands, rather than the coniferous forests found within the proposed Project Area. The conclusion from their report remains pertinent for the proposed Project, because avian mortality from wind developments is far less significant than the effect from traditional energy development or climate change. There are no other projects in coniferous forests in the west for comparison, so the Klickitat study was used. Only one other wind development is currently proposed, suggesting cumulative effects in this habitat type will remain very limited compared with other habitats. A revised cumulative impacts analysis that takes into consideration proposed wind energy development in coniferous forest habitats of western WA has been added to Section 3.14.3.5 of the FEIS.

Comment: Pre-construction estimates of avian and bat fatalities have not proved reliable. Although no scientists have done a thorough comparison of pre-construction and post-construction mortality estimates, there is plenty of anecdotal evidence that post-construction mortalities often greatly exceed pre-construction estimates made using the same methodology as has been employed for the Whistling Ridge wind project. For example, the Environmental Impact Statement (EIS) prepared prior to adoption of the Energy Overlay Zone in Klickitat County grossly underestimated the level of wildlife fatalities likely to result from wind development. At all of the wind projects in Klickitat County where monitoring has been completed or is under way, reports prepared by wildlife consultants show that fatalities of raptors and bats are far in excess of what was anticipated by the EIS. Whistling Ridge is using the same consultants and methodology as Klickitat County for its pre-construction fatality estimates. At Big Horn, the first large wind project built in Klickitat County, the developer's wildlife consultants did a full year of monitoring at 100 percent of the turbines, which makes this one of the most comprehensively monitored wind projects anywhere in the United States. The results of that monitoring study show that raptor fatalities are at least eight times higher than what the developer, PPM/Iberdrola, projected. [REFERENCE: Big Horn Wind Power Project Wildlife Fatality Monitoring Study 2006-2007. Prepared for PPM Energy and Big Horn Wind Project Technical Advisory Committee by Northwest Wildlife Consultants, Inc., 2008.] An independent study of Big Horn's monitoring results written by Dr. Smallwood concluded that raptor fatalities are up to 16 times higher than predicted prior to construction. [REFERENCE: Avian and Bat Mortality at the Big Horn Wind Energy Project, Klickitat County, Washington. K. Shawn Smallwood, 2008.] Big Horn also kills twice as many bats as anticipated, according to
fatality monitoring reports. Monitoring studies at other wind projects in Klickitat County are not yet completed, but the preliminary results from those projects suggest even higher fatality rates. The above-cited independent scientific analysis based on the results from Big Horn (the first of only two projects in Klickitat County where fatality monitoring has been completed) reported a conservative estimate of 243 raptor fatalities annually in Klickitat County. That estimate of 243 raptor fatalities is for a level of development that does not exceed 1,000 megawatts. At its current rate of wind development, Klickitat County is likely to reach a level of 2,000 megawatts or more within the next year or so. For raptors in Klickitat County, these numbers are rapidly approaching population-level impacts. “There is probably no other human source of mortality that comes close to these levels,” writes Dr. Smallwood. At the second project in Klickitat County where monitoring has been completed, Goodnoe, the results are similar. [REFERENCE: Goodnoe Hills Wind Project Avian Mortality Monitoring Report, Prepared for PacifiCorp by URS Corporation, March 16, 2010.] The final monitoring report for Goodnoe calculated fatalities of 0.34 raptors per year per turbine, or 0.17 raptors per megawatt per turbine, or 16 fatalities per year for the project. Only one project reviewed in the WEST report had a higher raptor fatality rate than the one found for Goodnoe. The Goodnoe project is killing far more raptors than predicted by pre-construction surveys. [LTR 161, CMT 7]

Response: There is a growing body of data available to compare pre-construction avian use estimates with post-construction mortality, and the pre-construction use estimates show a positive correlation with avian mortality. The methods used to show a disparity between pre-construction estimates and elevated post-construction mortality are being contested as not accurate.

Comment: With the completion of this DEIS, more biological review has been done than on any other previously sited wind project anywhere in the Northwest, let alone Washington [S]tate. To our knowledge, no other wind energy project has completed the multiple years of biological surveys, including three years of bat survey work. [LTR 162, CMT 8]

Response: Comment acknowledged.

Comment: In its “Section 7” consultation letter dated July 19, 2010, the USFWS confirmed that the project will no impact Northern Spotted Owls - a determination that should be considered conclusive on this issue. [LTR 162, CMT 9]

Response: Comment acknowledged.

Comment: This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat and would degrade the...
outstanding scenic beauty of the Columbia River Gorge National Scenic Area. [LTR 163, CMT 2]

Response: Comment acknowledged.

Comment: Thank you for the opportunity to review and comment on the joint NEPA SEPA Whistling Ridge draft environmental impact statement (DEIS). We looked primarily at fire hazard, plant species and communities, northern spotted owls and WA Department of Natural Resources' Habitat Conservation Plan (DNR HCP), forest practice requirements, and surface mines and reclamation. Some of our concerns include: the presence or impacts to Oregon white oak/Idaho fescue plant communities; northern spotted owls, their habitat and associated HCPs; forest practice requirements for this proposal, and a permitted source of aggregate for roads.
and structures. Our adjacent HCP land to the north is managed to provide habitat that makes a significant contribution to demographic support, maintenance of species distribution and facilitation of owl dispersal. [LTR 172, CMT 1]

**Response:** Comment acknowledged.

**Comment:** The DEIS on page 3-56 states there are no HCPs in or near the project area. Forest practices owl protection requirements were also not correctly explained. Please also note that state agency wildlife species review was typically done by WA Department of Fish and Wildlife (WDFW), and DNR biologists did not look at impacts to species not protected under the DNR forest land HCP in eastern Washington, other than compliance with Forest Practices Rules. [LTR 172, CMT 2]

**Response:** The Applicant must submit any harvest plan to DNR and WDFW for review and must abide by all forest practices owl protection requirements. If any harvest proposals fall within an HCP there is another layer of regulation that is required. All appropriate legal avenues were followed when submitting permits.

**Comment:** [In reference to DEIS Figure 2-2], the map shows a riparian area. The wetland is described in [DEIS Section 3.3.1.1, Surface Water] County protection measures are described on [DEIS Section 3.4.1.3] for category II wetlands. [Our] request [is] if this is on forest land you should verify if it is a Type A or Type B wetland and that the 100 foot buffer would also meet or exceed any FP Rule requirements for a Type A or B wetland (WAC 222-30-020) for that location. [LTR 172, CMT 14]

**Response:** The non-forested area of the Cedar Swamp wetland is considered to be a Type A wetland under Forest Practices regulations. According to WAC 222-30-020, the allowable buffer could range from 25 to 100 feet for this size of non-forested wetland community. However, this buffer is measured at transition from non-forested to forested wetland, which is inside the wetland boundary. Nevertheless, the 100-foot buffer on the wetland edge exceeds Forest Practices requirements.

**Comment:** [In reference to DEIS page] 3-50, the comment is made that the project is not sited in or near any Spotted Owls or Spotted Owl activity site centers. There are two Spotted Owl circles within portions of the proposal area. Request: Please correct the inaccurate statement concerning spotted owls. [In reference to DEIS pages] 3-50 and 3-53, [it is stated that] “the two Spotted Owl site centers are no longer considered to be occupied pursuant to USF & W protocols and state law.” This is an inaccurate statement. The two Spotted Owl circles are still in the state data base and have not been decertified as of this date. Forest Practices rules and regulations still require appropriate protections (WAC 222-16-080(6)). [DNR’s] Request: Please correct the inaccurate statement concerning spotted owls and correctly state the
appropriate FP Rule mitigation measures that are required. [In reference to DEIS pages] 3-75 and 3-78, [it is stated that] “The proposal would not impact the White Salmon SOSEA’s 40% suitable Spotted Owl habitat level.” This is an inaccurate statement. The habitat level is calculated on a circle by circle basis, not over the entire SOSEA. There is a small mapped portion of potential habitat in one of the two circles in the proposal. [DNR’s] Request: Please document whether this proposal (including all of the associated timber harvests) will harvest suitable owl habitat (WAC 222-16-085) and or impact the suitable habitat totals for one of the spotted owl circles, if that is the case (WAC 222-10-040) [LTR 172, CMT 17]

Response: The text in Section 3.4.1.5 (the last sentence on page 3-49 of the DEIS and the first full sentence on DEIS page 3-50) has been revised to read: “There are a total of 9 turbines proposed within the 1.8 mile provincial range of two NSO activity centers. There are no proposed turbines located within the 500 acre core areas of these activity centers. Two historical meeting sites on public lands near the property have not been used in over six and eight years, respectively, and are no longer considered to be occupied by USFW endorsed protocols but have not been decertified by WDFW or USFW and are still considered occupied by state and federal law.”

Comment: This letter responds to your request for consultation under section 7(a)(2) of the Endangered Species Act of 1973, (ESA) as amended (16 U.S.C. 1531 et seq.) on the proposed Whistling Ridge Energy Project LLC (Project). Your biological assessment (BA), dated June 8, 2010, was received by the U.S. Fish and Wildlife Service’s (Service) Washington Fish and Wildlife Office on June 9, 2010. You requested concurrence with your determination that the Project “may affect, but is not likely to adversely affect” the threatened northern spotted owl (Strix occidentalis caurina) (spotted owl). No designated spotted owl critical habitat occurs on or near the Project; therefore, no critical habitat will be affected. This letter is based on information provided in the BA, the 2009 Final Report “Results of Northern Owl, Western Gray Squirrel and Northern Goshawk Surveys Conducted for the Whistling Ridge Wind Energy Project”, the Draft Environmental Impact Statement, a field trip to the Project attended by staff of the Service and the Washington Department of Fish and Wildlife on May 14, 2009, and a meeting between Service and Washington Department of Fish and Wildlife staff on August 28, 2009. [LTR 173, CMT 1]

Response: Comment acknowledged.

Comment: Status of Spotted Owls in the Project Area. Two spotted owl territories are located on Washington State Department of Natural Resources (DNR) and National Forest lands located north of and adjacent to the Project. The site center for the Mill Creek owl (MSNO #0991) is located in Township 4 North, Range 10 East, Section 28 and the site center for the Moss Creek owl (MSNO #1003) is located in Township 4 North, Range 9 East, Section 35. Both of these owl territories are within Washington State’s White Salmon Spotted Owl Special Emphasis Area, which provides added protection for spotted owls located on private lands through the Washington State Forest Practices Rules. Both of the 70 acre core areas are located
on DNR lands and are provided additional protection from their Habitat Conservation Plan for the State Trust Lands. The estimated median annual home range size for the spotted owl in this physiographic province is approximately 6,657 acres, which for regulatory purposes is assumed to lie within a 1.8-mile radius circle. Best available science indicates that when the amount of suitable spotted owl habitat within a circle falls below 40 percent, there is a likelihood of “take” under section 9 of the ESA. Each of these territories contains more than 40 percent suitable spotted owl habitat (J. Spadaro, pers. com. 2009). A small portion of the Moss Creek circle overlaps the northern end of the Project and contains dispersal habitat and some foraging habitat. However, removal of this small amount of habitat (2 acres) would not reduce the habitat acreage below 40 percent in either territory. Protocol spotted owl surveys were conducted within these estimated home ranges during the 2003, 2004, 2008, and 2009 breeding seasons. Numerous barred owls (Strix varia) were detected, but no spotted owls were detected; however, because of the presence of barred owls with these territories, it is possible that spotted owls were present but did not vocalize. The 2009 surveys followed the Service’s revised 2010 protocol to better elicit spotted owl responses in the presence of barred owls (USFWS 2010) (the consultant contacted the U.S. Fish and Wildlife Service on May 29, 2009, how to call for spotted owls in light of the numerous barred owl detections north of the Project and was provided the changes to the 1992 surveying protocol prior to the release of the 2010 revised protocol on February 18, 2010). However, in 2010 surveys were continued in the Project area. On May 6, 2010, a single male spotted owl was detected while conducting a night visit in the far north edge of the Mill Creek provincial range on DNR property. On May 7th, the biologist conducted a follow-up visit during the daytime. The bird exhibited non-nesting behaviors. On May 29, the biologist conducted a second visit and located what appeared to be the same male owl that was detected on May 7th. The bird on both survey visits took and consumed mice, indicating that it is a single male not supporting young. Spotted owl survey protocol requires 3 sightings of a spotted owl single within the same area within the breeding season to be regarded as a territorial single. This does not change the analyses of effects of the Project to spotted owls, as addressed below, regardless of whether or not a territorial status is established. Effects from Construction. Approximately 2 acres of spotted owl dispersal habitat (with some patches of foraging habitat) would be removed from the Moss Creek spotted owl site by the construction of the Project from the northern end of the turbine string. This habitat is located at the southern extremity of the circle and is on the edge of the Project that has already been clear-cut by SDS Lumber Company, and would not remove suitable spotted owl habitat below 40 percent in the territory (J. Spadaro, pers. com. 2009). The discovery of the new owl in 2010 in the extreme north of the Moss Creek owl circle is located more than 2 miles northwest of the northern-most turbine. Because of this and since the remainder of the Project does not contain suitable spotted owl habitat, we believe that potential effects to spotted owls as a result of habitat loss or degradation is expected to be insignificant. [LTR 173, CMT 4]

Response: Comment acknowledged.

Comment: Effects from Maintenance. The effects of the operation and maintenance of the Project are anticipated to be minor. Maintenance of the Project would occur primarily around the turbine pads, inside the nacelle (the nacelle is the part of the turbine that houses the generator, transmission gears, and the shaft that turns the generator that, on its opposite end,
bolts to the hub that the blades attach to) and the blades. In addition, because the landscape will be maintained as young second-growth forest we do not expect disturbance to nesting owls from maintenance because owls are not likely to nest in these younger forest stands (non-habitat). 

Risk of Spotted Owl Collision with Wind Turbines. Bird mortality from collisions with wind turbines is well documented and varies greatly by bird species and flight behavior (Smallwood et al. 2009). Spotted owls are forest-dwelling birds that are strongly associated with older conifer forests. Spotted owls primarily use closed-canopy forested habitats throughout their entire lives for nesting, roosting, foraging, and dispersal (Forsman et al. 1984). Because spotted owls are non-migratory, forest-dwelling owls, they are at much lower risk of exposure to wind turbines than many other bird species, which typically use non-forested upland habitats for foraging and migration. Spotted owls less commonly use recent clear-cuts or burned areas for foraging, but spotted owls do occasionally cross such areas while dispersing between patches of older forest (Forsman et al. 1984; 2002). Although spotted owls do occasionally disperse across open areas, they usually avoid crossing such areas by traveling through corridors of forested habitat (Forsman et al. 1984). The typical flight behavior of the spotted owls is described in the Birds of North America: “Quick wingbeats interspersed with gliding flight. Not a fast flier. Long flights unusual except during dispersal...Flight labored when attempting to fly to a higher perch or up to nest sites. When gaining altitude in the forest canopy, makes a series of short climbing flights rather than continuous flight. Flights above the forest canopy probably rare except during dispersal. (Gutierrez et al 1995, p.9).” During natal dispersal, spotted owls will occasionally cross open areas and, as notes above, may occasionally fly above the level of the forest canopy. Considering spotted owl flight behavior above-canopy flights are most likely to occur in steep-walled valley settings, where the spotted owl may choose to fly across a valley above the level of the forest canopy on the valley floor. The Whistling Ridge site is located on a forested ridge top that will be maintained as a cleared area for the wind turbines. Spotted owls dispersing across the ridge are more likely to disperse through forested areas along the perimeter of the site, rather than crossing the open areas near the turbines. If a spotted owl were to fly through the turbine array, it would most likely cross at an altitude that is at or below the level of the adjacent forest canopy, and well below the height of the lower of the wind turbine blades (164-425 ft. above ground level). To assess the risk of owl collision with the turbine blades or towers, we convened a review panel of three spotted owl biologists from this office and one spotted owl biologist from the Washington Department of Fish and Wildlife. Based on our knowledge of spotted owl flight behaviors and habitat preferences, the group concluded that the risk of spotted owl collisions with turbines at this site is low. Considering the strong association of spotted owls with the forest canopy, and spotted owl flight behaviors, we conclude that it is unlikely that spotted owls would cross the Whistling Ridge site at an altitude that would put the owls at risk of collision with turbine blades. Therefore, the risk of a spotted owl collision at this site is considered to be discountable. Concurrence. Considering the current status of spotted owls in the Project area, and the anticipated Project effects, we concur that the Project is not likely to adversely affect the spotted owl. This concludes informal consultation pursuant to the regulations implementing the ESA (50 CFR 402.13). This action should be re-analyzed if new information reveals effects of the action that may affect listed species or designated critical habitat in a manner or to an extent not considered in this consultation; if the action is subsequently modified in a manner that causes an effect to an listed species or designated critical habitat that was not considered in this consultation; and/or, if a new species or critical habitat is designated that may be affected by this Project. [LTR 173, CMT 4]
Response: Comment acknowledged.

Comment: While reading through the DEIS for this Project, we found some issues that require your attention. On [DEIS] Page 4-4, first paragraph, last sentence “As described in Section 3.4 Biological Resources, no listed species or critical habitat are anticipated to be affected by the Project.” This statement equates to a finding of no effect. To the contrary, the biological assessment prepared by BPA made a finding of “may affect, not likely to adversely affect”; hence, the need for this informal consultation. [LTR 173, CMT 5]
