Whistling Ridge Energy Project
Final Environmental Impact Statement

August 2011

Washington State Environmental Policy Act Lead Agency:
State of Washington, Energy Facility Site Evaluation Council
This Final Environmental Impact Statement has been issued by the Washington State Energy Facility Site Evaluation Council (EFSEC) to fulfill its lead agency responsibilities under EFSEC’s SEPA rules at Washington Administrative Code (WAC) 463-47-150. The Bonneville Power Administration (BPA) also will be issuing this FEIS to meet its obligations under the National Environmental Policy Act (NEPA) before it makes a decision on whether to allow an interconnection of the proposed project to the BPA transmission system. EFSEC and BPA have worked together to ensure that this joint FEIS meets the requirements of both SEPA and NEPA.
Note to Reader: This Final EIS revises and updates the information presented in the Draft EIS for the Whistling Ridge Energy Project issued in May 2010. New or revised text is shown in red underlined font and deleted text is crossed out with a solid black line (e.g. example). Changes to tables, graphs, and other figures are indicated using similar editorial techniques.
# TABLE OF CONTENTS

1.0 SUMMARY AND PURPOSE OF AND NEED FOR ACTION ......................... 1-1

1.1 Introduction ........................................................................................................ 1-1

1.2 Purpose of and Need for Action ........................................................................ 1-3
  1.2.1 EFSEC’s Purpose and Need for Action ......................................................... 1-3
  1.2.2 Bonneville Power Administration Purpose of and Need for Action .............. 1-4
  1.2.3 Applicant-Identified Needs .......................................................................... 1-4
    1.2.3.1 Regional Need for New Sources of Renewable Energy .................................. 1-4
    1.2.3.2 Need for Reliable Transmission for the Proposed Project .......................... 1-6
    1.2.3.3 Business Needs of the Applicant ............................................................... 1-6

1.3 SEPA/NEPA Compliance and Decision-Making .................................................. 1-7
  1.3.1 EIS Lead Agencies ....................................................................................... 1-7
  1.3.2 Uses Of This EIS ......................................................................................... 1-8
  1.3.3 Integration Of SEPA and NEPA Requirements .............................................. 1-8

1.4 Description Of Alternatives .............................................................................. 1-9
  1.4.1 Proposed Action ............................................................................................. 1-9
    1.4.1.1 Wind Turbines .......................................................................................... 1-10
    1.4.1.2 Electrical Collector System ....................................................................... 1-10
    1.4.1.3 Project Collector Substation and Interconnection to the FCRTS ......................... 1-10
    1.4.1.4 Operations and Maintenance Facility ....................................................... 1-11
    1.4.1.5 Water Supply and Wastewater ................................................................. 1-11
    1.4.1.6 Site Access for Construction and Operation ............................................. 1-12
  1.4.2 No Action Alternative ..................................................................................... 1-12
  1.4.3 Alternatives Considered But Eliminated From Detailed Study .................... 1-13
    1.4.3.1 Alternative Project Locations ................................................................. 1-14
    1.4.3.2 Larger or Smaller Generation Facility Size ................................................. 1-14
    1.4.3.3 Alternative Wind Generation Technologies .............................................. 1-15
    1.4.3.4 Alternative Project Configurations ............................................................ 1-15
    1.4.3.5 Alternative Interconnections ................................................................. 1-15
    1.4.3.6 Alternative Access Roads ................................................................. 1-16

1.5 Summary of Public Involvement, Consultation, and Coordination ................. 1-16
  1.5.1 Public and Agency Scoping ............................................................................ 1-16
  1.5.2 Agency Consultations ................................................................................... 1-18
  1.5.3 Applicant Meetings and Consultation ............................................................. 1-19
    1.5.3.1 Local Government .................................................................................... 1-19
    1.5.3.2 State Government ..................................................................................... 1-20
    1.5.3.3 Federal Government .................................................................................. 1-21
    1.5.3.4 Tribal Government .................................................................................... 1-21
Whistling Ridge Energy Project
Final Environmental Impact Statement

Table of Contents

1.5.3.5 Railroad................................................................. 1-22
1.5.4 Draft EIS Comment Period and Public Meetings ............ 1-22
1.6 Summary of Potential Project Impacts and Mitigation Measures ........................................... 1-22
1.7 Summary Of Unavoidable Adverse Impacts ........................ 1-35
1.8 Cumulative Impacts ........................................................................ 1-36
1.8.1 Projects Considered .......................................................... 1-37
1.8.1.1 Existing Development.............................................. 1-37
1.8.1.2 Reasonably Foreseeable Future Development............ 1-37
1.8.2 Results Of Cumulative Impacts Analysis .......................... 1-39
1.9 Organization Of This EIS .................................................... 1-39
1.10 References.............................................................................. 1-40
2.0 PROPOSED ACTION AND ALTERNATIVES .......................... 2-1
2.1 Proposed Action........................................................................ 2-1
2.1.1 Wind Power In General .................................................. 2-1
2.1.2 Project Overview .......................................................... 2-2
2.1.3 Project Components .......................................................... 2-5
2.1.3.1 Wind Turbines ....................................................... 2-5
2.1.3.2 Electrical Collector System........................................ 2-6
2.1.3.3 Project Substation and Interconnection ................. 2-6
2.1.3.4 Operations and Maintenance Facility ...................... 2-7
2.1.3.5 Meteorological Tower............................................ 2-7
2.1.3.6 Water Supply and Wastewater.............................. 2-7
2.1.3.7 Access Roads ..................................................... 2-8
2.1.4 Project Construction.......................................................... 2-9
2.1.4.1 Construction Activities ........................................ 2-9
2.1.4.2 Construction Schedule ........................................ 2-12
2.1.4.3 Construction Manpower and Truck Trips ............ 2-12
2.1.4.4 Construction Costs and Fiscal Considerations ....... 2-14
2.1.5 Project Operation .......................................................... 2-14
2.1.6 Forest Harvest During Project Construction and Operation ........................................ 2-14
2.1.7 Project Decommissioning .................................................. 2-18
2.2 No Action Alternative.............................................................. 2-18
2.3 Alternatives considered But Eliminated From Detailed Study ........................................... 2-19
2.3.1 Alternative Project Locations ........................................ 2-20
2.3.2 Larger or Smaller Generation Facility Size .................... 2-21
2.3.3 Alternative Wind Generation Technologies ................. 2-22
2.3.4 Alternative Project Configurations .................................. 2-22
2.3.5 Alternative Interconnections ......................................... 2-22
2.3.6 Alternative Access Roads ............................................... 2-23
2.4 Benefits and Disadvantages of Delaying Project Implementation ........................................ 2-24
2.5 Comparison Of Alternatives ............................................... 2-25
2.6 References.............................................................................. 2-27

1.0 SUMMARY AND PURPOSE OF AND NEED FOR ACTION

1.1 INTRODUCTION

Whistling Ridge Energy LLC (the Applicant) proposes to construct and operate the Whistling Ridge Energy Project (the Project) approximately 7 miles north of the City of White Salmon in Skamania County, Washington (Figure 1-1). The proposed Project would be an approximately 75-megawatt (MW) wind turbine facility located within an approximately 1,152-acre Project Area on land that is currently private commercial forest land. The facility would be located on north-trending ridges that range in elevation from about 2,100 to 2,300 feet above mean sea level (msl). There is a proven wind resource at the site of the proposed Project Area. The proposed Project would consist of up to 50 wind turbines that could each range in size from 1.2 to 2.5 MW. The proposed Project also includes an Operations and Maintenance facility, an electrical collector substation, underground collector lines and systems, and other ancillary facilities.

The Applicant has submitted an application to the Washington State Energy Facility Site Evaluation Council (EFSEC) for site certification that would allow the Applicant to construct and operate the Whistling Ridge Energy Project. The Application is included as Appendix A to this EIS. As part of its responsibilities for evaluating this application, EFSEC must conduct an environmental review of the proposed energy facility under the Washington State Environmental Policy Act (SEPA). The Applicant has also requested interconnection of the proposed Project to the regional transmission system owned and operated by the Bonneville Power Administration (BPA), which is a federal agency. Interconnection of the Whistling Ridge Energy Project to the regional transmission system would require construction of a new BPA substation and related electrical equipment within the Project Area. As part of its consideration of the Applicant’s interconnection request, BPA must evaluate the proposed interconnection under the National Environmental Policy Act (NEPA).

Accordingly, EFSEC and BPA have prepared this joint environmental impact statement (EIS) to be consistent with the requirements of both SEPA and NEPA. Because of the State of Washington’s primary role in the siting of the proposed Project, this EIS generally follows the EIS format and content guidance contained in Washington Administrative Code (WAC) 197-11, as adopted by EFSEC through WAC 463-47. However, the EIS format and content has been modified, adjusted, and expanded where appropriate to ensure compliance with NEPA, as well.

The remainder of this chapter of the EIS describes the purpose of and need for action concerning the proposed Project, and further discusses the two agencies’ approach to SEPA and NEPA compliance and decision-making for this Project. This chapter also summarizes the proposed Project and alternatives, identifies public involvement activities, and summarizes Project impacts and mitigation measures. An outline of the organization of this EIS is provided at the end of this chapter.
Figure 1-1
Location of Proposed
Whistling Ridge Energy Project

1.2 PURPOSE OF AND NEED FOR ACTION

This section describes the respective need for action by EFSEC and BPA concerning the Applicant’s proposed Whistling Ridge Energy Project, as well as purposes or objectives that these two agencies will consider in their respective decisions concerning the Project. This section also identifies various needs that the Applicant is responding to in proposing the Project.

1.2.1 EFSEC’S PURPOSE AND NEED FOR ACTION

On March 10, 2009, the Applicant submitted an Application for Site Certification (ASC 2009-01) to EFSEC to construct and operate the Whistling Ridge Energy Project in accordance with WAC 463-42. The Applicant chose to apply for certification of the proposed Project according to the Revised Code of Washington (RCW) 80.50.060, under which EFSEC has siting jurisdiction over energy facilities, such as the proposed Project, in the state of Washington.

EFSEC is a Washington State board comprised of a Chairman appointed by the Governor and representatives from five state agencies. The Council is augmented by representatives from the particular counties, cities, or port districts where potential projects may be located, as well as additional state agencies that can opt into the review of a new proposal. The Council is responsible for evaluating applications to ensure that all environmental and socioeconomic impacts are considered before a site is approved.

In accordance with RCW 80.50.040, EFSEC must review and act on the Application in the following ways:

- Prepare written reports to the governor which shall include: (1) A statement indicating whether the application is in compliance with the council's guidelines, (2) criteria specific to the site and transmission line routing, (3) a council recommendation as to the disposition of the application, and (4) a draft certification agreement when the council recommends approval of the application;

- Prescribe the means for monitoring of the effects arising from the construction and the operation of energy facilities to assure continued compliance with terms of certification and/or permits issued by the council;

- Integrate its site evaluation activity with activities of federal agencies having jurisdiction in such matters to avoid unnecessary duplication;

- Present state concerns and interests to other states, regional organizations, and the federal government on the location, construction, and operation of any energy facility which may affect the environment, health, or safety of the citizens of the state of Washington; and

- Issue permits in compliance with applicable provisions of the federally approved state implementation plan adopted in accordance with the Federal Clean Air Act, as now existing or hereafter amended, for the new construction, reconstruction, or enlargement or operation of energy facilities.
1.2.2 BONNEVILLE POWER ADMINISTRATION PURPOSE OF AND NEED FOR ACTION

BPA owns and operates the federal transmission system in the Pacific Northwest. This system, which is referred to as the Federal Columbia River Transmission System (FCRTS), consists of more than 15,000 circuit miles of high-voltage (115-kilovolt [kV] and above) electric transmission lines. These transmission lines are used to move most of the power from Pacific Northwest generating facilities to power users throughout the Northwest and nearby interconnected regions.

BPA has adopted an Open Access Transmission Tariff, which is generally consistent with the Federal Energy Regulatory Commission’s pro forma open access tariff. Under BPA’s tariff, BPA offers transmission interconnection to the FCRTS to all eligible customers on a first-come, first-served basis, with a decision on whether or not to make this offer subject to environmental review under NEPA. Electricity generated by the Project would be delivered to the BPA electric grid via a new transmission interconnection.

The Applicant has requested interconnection of its proposed Project to BPA’s existing North Bonneville-Midway 230-kV transmission line, a portion of the FCRTS that traverses the Project Area. In response, BPA will consider the following objectives or purposes in deciding whether to grant the request:

- Maintain the electrical stability and reliability of the FCRTS;
- Continue to meet BPA’s statutory and contractual obligations;
- Act consistently with BPA’s environmental and social responsibilities; and
- Provide for cost and administrative efficiency.

Although BPA is considering interconnecting the Project, BPA is not considering acquiring any of the output of the proposed Project. In addition, BPA has no siting authority for the proposed Project.

1.2.3 APPLICANT-IDENTIFIED NEEDS

The Applicant’s purpose in proposing the Whistling Ridge Energy Project is to help meet the future need for energy resources, while at the same time enabling the Applicant to further diversify its business through a technically and economically feasible project. This section identifies the regional needs for this proposed Project that have been identified by the Applicant, as well as the Applicant’s needs that would be met by the Project.

1.2.3.1 Regional Need for New Sources of Renewable Energy

The Fifth Northwest Electric Power and Conservation Plan was issued by the Northwest Power and Conservation Council (NPCC) in May 2005. The Plan found that Northwest electricity demand was projected to grow at an average annual rate of nearly 1 percent per year, resulting in an over 5,000-MW deficit by 2025 using the medium forecast.
The Fifth Power Plan states that: “Renewable resources are also a priority resource in the Northwest Power Act. Like conservation, their potential and cost-effectiveness are sensitive to developing technology and the cost of more traditional generating alternatives. Renewables have potential risk reduction benefits related to their ability to hedge risks of fuel price volatility and the risks of possible measures to mitigate greenhouse gas emissions.”

In September 2009, the NPCC released the Draft Sixth Northwest Power Plan (NPCC 2009), which contains projections for regional power demand. The plan notes that regional population in Idaho, Montana, Oregon, and Washington is likely to increase from 12.7 million in 2007 to 16.3 million by 2030. This 3.6 million increase in population compares to a 3.8 million increase between 1985 and 2007. The population growth will be focused on older-age categories as the baby boom generation reaches retirement age.

The cost of energy of all types is expected to be significantly higher over the next twenty years than during the 1980s and 1990s. Cost increases will be driven by increasing demand and the fact that the cost of finding and producing new energy sources is higher than for conventional supplies. Carbon emission taxes or cap-and-trade policies are likely to further raise energy costs. The NPCC predicts that wholesale electricity prices are expected to increase from about $45 per MW-hour in 2010 to $85 by 2030 (2006$).

Demand for electricity is expected to grow. The plan states that “The Pacific Northwest consumed 19,000 average megawatts or 166 million megawatt-hours of electricity in 2007. That demand is expected to grow to 25,000 average megawatts by 2030 in the Council’s medium forecast. Between 2007 and 2030, demand is expected to increase by a total of 6,500 average megawatts, growing on average by 270 average megawatts, or 1.2 percent, per year.”

According to the NPCC, much of the future demand for electricity in the region could be met through conservation. However, markets for renewable or “green” energy are still growing in the Pacific Northwest. One driver for this shift is the establishment of Renewable Portfolio Standards (RPS) at the state level, which requires that utilities obtain a percentage of their power from renewable sources. For example, in 2006, voters in Washington passed Initiative 937, which requires that by 2020 large public and private utilities must obtain 15 percent of their electricity from renewable resources, and undertake cost-effective energy conservation. In 2008, California increased its RPS goal from 20 percent to 33 percent renewable energy by 2020.

In addition to the RPS requirements, Washington law requires larger utilities in Washington to offer a voluntary “qualified alternative energy product,” essentially an electricity product powered by green resources, beginning January 2012. State law defines a qualified alternative energy resource as electricity fueled by wind, solar energy, geothermal energy, landfill gas, wave or tidal action, gas produced during the treatment of wastewater, qualified hydropower, or biomass. As of 2008, 15 of the 16 utilities covered by the report had an active green power program with customers participating, and five additional utilities not covered by the law reported to the state that they were operating green power programs. Estimated sales of green power for 2008 were up 17 percent over 2007. Wind powered electricity represented 83.3 percent of green power sales (WUTC and CTED 2008).

In recent reports to the Washington State Legislature, the Washington Department of Commerce (formerly the Department of Community, Trade and Economic Development, CTED) has found
that: “...the region should begin an aggressive program to capture the large amount of cost-effective conservation that is available and to lay the groundwork for building a large amount of wind generation...” (Washington CTED 2005).

More recently, state policy has been driven by the electorate’s enactment of an RPS that requires all but the state’s smallest utilities to acquire new sources of renewable energy with which to supply consumers with clean electricity. This policy, mandated by the voters, resembles similar (though more aggressive) standards in Oregon and California, and has spurred active development of potential wind energy resources within the state to serve in-state utilities.

The RPS, coupled with load growth in Washington’s urban areas, has prompted investor-owned and public power utilities to seek new sources, most often developed by independent power producers, to meet their resource goals.

1.2.3.2 Need for Reliable Transmission for the Proposed Project

Power generation resources typically require interconnection with a high-voltage electrical transmission system for delivery to purchasing retail utilities. Goals and policies aimed at reducing greenhouse gas emissions are driving the need for new resources such as wind-powered projects, yet the location of such projects is constrained by the availability of high voltage transmission lines.

Transmission planning and construction can be the longest lead-time item in power plant development. While lead times for the development of new generation have become shorter, the lead time for major transmission improvements and their costs can be a major barrier to acquisition of needed and cost-effective resources. For some projects, the lead time for the development of new transmission can be as much as seven years, and the cost of the transmission can be somewhat more than half the total capital cost of a project.

In order to provide new energy resources within the next three to five years, it is critical to locate projects in areas where transmission lines currently exist. The Applicant thus needs to locate near existing high-voltage transmission, such as the FCRTS.

1.2.3.3 Business Needs of the Applicant

As stated in Section 1.1, the Applicant for the Whistling Ridge Energy Project is Whistling Ridge Energy LLC, which is a limited liability corporation operating in the State of Washington. Whistling Ridge Energy LLC has been formed by S.D.S. Co., LLC, which is an affiliated entity of SDS Lumber Company (SDS). The Applicant has owned and operated a wood products manufacturing facility in Bingen, Washington continuously since 1946. Operations include lumber and plywood manufacturing, log handling and transportation, marine transportation and construction, log chipping for the pulp and paper industry, biomass energy generation, and other land development and land use ventures in the Skamania and Klickitat County area.

When the company began in 1946, there were 26 employees in its original crew. This number grew to a high of 450 employees during the 1970s when logging and lumber production were at a peak. Production has since slowed tremendously, as the supply of timber from national forests has sharply declined due to environmental legislation. For this reason, many of the mills in
Skamania County have closed down. The Applicant was able to survive the crises and changes of the last 30 years and no longer relies on timber from national forests. While the company has scaled back operations, today they are one of the largest employers in Klickitat County, Washington, employing 325 people during their busiest production times.

The company has remained viable during changes in the market through expanding and diversifying its enterprises beginning in 1978 to include power produced in its steam-operated power plant, which creates energy from wood waste, a renewable, organic resource, and to include marine services in 1984. The proposed Whistling Ridge Energy Project is intended to provide another means of diversifying the holdings of the company to ensure a continuation of a resource-based work force in Skamania County, to create new construction and operation jobs at a time when jobs in Washington State are being lost, and to help to diversify the tax base of Skamania County.

The Applicant also seeks to provide an additional renewable resource for electric utilities in Washington. As described above and enacted in November 2006 as Initiative 937, each Washington utility serving more than 25,000 customers is required to meet specific targets for using eligible renewable resources to produce electricity. Examples of eligible renewable resources include wind energy facilities, solar panels, and geothermal plants. Each utility would have to use renewable resources to serve at least 3% of its load by 2012 through 2015; 9% of its load by 2016 through 2019, and 15% of its load by 2020.

As it has done in the past, the Applicant seeks to create new business and job opportunities through diversifying and maximizing the use of its existing holdings. A wind power project presents a new opportunity to the Applicant to provide green energy, but only if it fits with its existing business uses and its existing holdings, and is located in an area where generated electricity can be delivered to urban power markets.

1.3 SEPA/NEPA COMPLIANCE AND DECISION-MAKING

1.3.1 EIS LEAD AGENCIES

As discussed in Section 1.2.1, the Applicant has chosen to apply for site certification of the proposed Whistling Ridge Energy Project from Washington EFSEC, which has siting jurisdiction over energy facilities, such as the proposed Project, in the state of Washington. Because of its primary role as the project siting authority, EFSEC is the SEPA lead agency for this EIS.

As discussed in Section 1.2.2, the Applicant also has requested interconnection of the proposed Whistling Ridge Energy Project to the FCRTS, which is owned and operated by BPA. As a federal agency, BPA must consider the environmental consequences of its proposed actions—in this case, the proposed interconnection of the Project to the FCRTS—under NEPA prior to making a decision on whether to proceed with the proposed action. The proposed approval of the requested interconnection is the main federal proposed action related to the proposed Whistling Ridge Energy Project. BPA, therefore, is the NEPA lead agency for this EIS. While several federal agencies participated in the NEPA review for this Project, no federal agency has served as a cooperating agency (pursuant to 40 CFR § 1501.6) during the preparation of this EIS.
1.3.2 USES OF THIS EIS

This EIS will be used primarily to inform the lead agencies, the public, and other interested and affected parties about the potential environmental consequences of the proposed Whistling Ridge Energy Project, as required by SEPA and NEPA. The draft EIS was distributed to the public and other interested parties, and was used to solicit comments on the adequacy and accuracy of the environmental analysis contained in the draft EIS. Distribution of the draft EIS provided the public with information about the Project and its environmental effects, while simultaneously allowing an opportunity for meaningful public participation and comment on the draft EIS. All responses to comments received on the draft EIS are presented in Appendix G. All comment letters are presented in Appendix H.

In addition to providing the public with updated environmental information, the final EIS will be used to inform agency decisions on whether or not to issue authorizations and approvals for the proposed Project, consistent with the requirements of SEPA and NEPA. More specifically, EFSEC will use the final EIS to inform its decision on whether to recommend approval or denial of the Whistling Ridge Energy Project to the Governor of Washington. The Governor then will make a decision on whether to approve or deny the proposed Project. BPA will use the final EIS to inform its decision on whether to grant the requested interconnection of the Project to the FCRTS. BPA grants such requests by offering a final Large Generator Interconnection Agreement to a party requesting interconnection (such as the Applicant), pursuant to its tariff.

Other federal, state or local agencies also may have permitting or other approval authority for the proposed Whistling Ridge Energy Program (see Chapter 4). Those agencies may use this EIS in order to fulfill their NEPA or SEPA responsibilities.

1.3.3 INTEGRATION OF SEPA AND NEPA REQUIREMENTS

As indicated in Section 1.1, this EIS has been prepared as a joint SEPA/NEPA EIS. As such, it is intended to fulfill the format and content requirements, as well as the spirit, of both of these statutes and their implementing regulations and associated guidance documents. Preparation of a joint SEPA/NEPA EIS for a project that requires both state and federal decisions is encouraged by both the State of Washington and the federal government.

At the state level, the Washington Department of Ecology (Ecology), the state agency charged with issuing uniform SEPA rules and guidelines for the state, has prepared the SEPA Handbook (Ecology 1998) to provide guidance on implementing SEPA requirements. Chapter 9 of the SEPA Handbook specifically recognizes that the SEPA and NEPA lead agencies for a proposed project may agree to be co-lead agencies, and encourages the preparation of a combined, or joint, SEPA/NEPA EIS in such situations to meet the requirements of both SEPA and NEPA.

At the federal level, the Council on Environmental Quality (CEQ) NEPA regulations specifically provide that state and local agencies may act with at least one federal agency as joint lead agencies for an EIS (See 40 CFR § 1501.5[b]). These regulations also specify that federal agencies shall cooperate with state and local agencies to the fullest extent possible to avoid duplication between NEPA and comparable state requirements (See 40 CFR § 1506.2[c]). Under 1506.2(c), this cooperation shall include preparation of a joint state-federal EIS where both state
and federal decisions approvals are involved, and the state and federal lead agencies are to act as joint lead agencies for the EIS.

Much of the organization of this document is based on the SEPA EIS format and content specified in WAC 197-11-430 and 197-11-440, with adjustments made to ensure NEPA compliance as well.

1.4 DESCRIPTION OF ALTERNATIVES

Two alternatives are evaluated in this EIS: the Proposed Action (authorizing construction and operation of the proposed Whistling Ridge Energy Project and associated components, and BPA granting the proposed interconnection) and the No Action alternative (not authorizing construction and operation of the proposed Project and associated components, and BPA not granting the proposed interconnection). These alternatives are summarized below. Alternative wind energy technologies, alternative wind turbine locations, and off-site alternatives considered but eliminated from further study in this EIS also are described.

1.4.1 PROPOSED ACTION

Under the Proposed Action, the state of Washington (acting through Washington EFSEC and the Governor of Washington) would approve the Site Certificate for the proposed Whistling Ridge Energy Project, thereby authorizing the Applicant to construct and operate the Project. Upon the issuance of the Site Certificate, BPA will concurrently issue its Record of Decision (ROD) and will thereby grant interconnection access to the Applicant under its Open Access Tariff. The proposed Whistling Ridge Energy Project would be located on an approximately 1,152-acre site approximately seven miles northwest of the City of White Salmon in Skamania County, Washington (Figure 1-1). The Applicant has identified this site for the proposed Project based on many factors, including:

- The site has a proven, robust wind resource;
- The site is large enough to accommodate enough wind turbines to produce a minimum of 70 MW nameplate capacity of electricity;
- The site is owned and controlled by the Applicant;
- The site has a long history of commercial logging and associated absence of native habitat, reducing or eliminating the need to clear additional forest land. Native species remain; however, the native habitat has been disturbed through commercial forestry activities;
- The site is uniquely suited for its access to on-site high voltage transmission in proximity to urban power markets; and
- The site is in proximity to the mill site and business offices of the Applicant.

The proposed Project would consist of wind turbine generators and associated components, and would have a total nameplate capacity of up to 75 MW. Approximately 384 acres would be developed for the wind turbine foundations, connecting roadways, and overhead and underground transmission lines. Information about the proposed wind turbines and other project components is summarized below.
1.4.1.1 Wind Turbines

The proposed Project would consist of up to 50 wind turbine generators, each of which would likely range in size from 1.2 to 2.5 MW, for a total of up to 75 MW. Each turbine would be up to approximately 426 feet tall (262-foot hub height and 164-foot radius blades, measured from the ground to the turbine blade tip), and would be mounted on a concrete foundation. Wind turbines would be grouped in “strings,” each spaced approximately 350 to 800 feet from the next (or approximately 1.5 to 2.5 times the diameter of the turbine rotor). The turbines throughout the Project would all be the same model, although height may vary in response to terrain.

Each wind turbine would consist of four main components: the turbine tower, the nacelle, the rotor hub, and the blades. Each turbine tower would be a tapered, hollow tubular structure, approximately 14 feet in diameter at the base and weighing approximately 30 tons. The towers would likely be painted a flat neutral gray or white color. Each tower would be mounted on a concrete foundation with a diameter up to approximately 60 feet. Tower foundations would be spread footing or pier-type footings. To the extent required by the Federal Aviation Administration, turbine towers would be furnished with blinking lights visible to aircraft.

The remaining three turbine components are all mounted at the top of each turbine tower. The nacelle is encased in fiberglass, and is mounted on top of the tower to house the gearbox, the generator, and the control system. The rotor hub is attached to the nacelle, and holds the blades in place. Each turbine has three laminated fiberglass blades, each approximately 129 to 164 feet long, depending on which turbine is selected. The diameter of the circle swept by the rotors would be approximately 264 to 320 feet, depending on which turbine is selected. The wind turbines would operate at wind speeds from 9 to 56 miles per hour (mph), with a rotor speed range of 10 to 20 revolutions per minute (rpm).

1.4.1.2 Electrical Collector System

The Project would include an electrical collector system to collect energy generated at approximately 575 volts (V) from each wind turbine, transform the voltage of this energy to 34.5-kV using a pad-mounted transformer, and deliver the energy via underground cables to the proposed Project substation. Each turbine’s 575-V to 34.5-kV transformer would be located on a transformer pad adjacent to each tower, or enclosed in the nacelle, depending on the turbine model. From there, power would be transmitted via underground 34.5-kV electric cables. These cables would be buried by digging trenches up to 5 feet wide and approximately 3 to 4 feet deep, placing the cables in these trenches, and then filling the trenches back in with the excavated soils. In areas where collector cables from several strings of turbines follow the same alignment (for example, near the proposed substation) multiple sets of cables would be installed within each trench where possible. There would be approximately 8.5 miles of underground collector cable trenches. In areas where environmental constraints, geologic features, or cultural features necessitate, minor aboveground placement of collector cables may occur.

1.4.1.3 Project Collector Substation and Interconnection to the FCRTS

The Project also would include a project collector substation, which would further transform the energy delivered by the underground electrical collector system from 34.5-kV to 230-kV, so that it would be suitable for delivery to the FCRTS. The proposed collector substation would occupy
a portion of a fenced 5-acre area at the southwest end of the Project Area, immediately adjacent to BPA’s transmission line. A 50-foot cleared area would be maintained around the substation. The substation site would be a graveled, fenced area with transformer and switching equipment and an area to park utility vehicles.

Additionally, the Project would include the construction of a new BPA substation located within the Project Area which would interconnect the Project into BPA’s North Bonneville-Midway 230-kV transmission line. The proposed BPA substation would cover an area of approximately 430 feet by 430 feet or approximately 4.25 acres. This area would be fenced, graded and graveled. Inside the fence, there would be a control house, six 230-kV disconnect switches, three 230-kV power circuit breakers, steel structures and towers, insulators and bus work. There would be a graveled access road to the site as well as access roads running underneath the additional transmission line structures that would be built. This development of 4.25 acres would be sufficient for future installation of equipment if required for future development.

The interconnection would be made through a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation. The loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line could cross underneath for this interconnection.

1.4.1.4 Operations and Maintenance Facility

A permanent Operations and Maintenance facility would be constructed on an approximately 5-acre area located at one of the following two locations: (1) adjacent to the proposed substation; or (2) west of the Project Area along West Pit Road. The Operations and Maintenance building would have approximately 3,000 square feet of enclosed space, including office and workshop areas, a kitchen, bathroom, shower, and a utility sink. It would be constructed of sheet metal, and would be approximately 16 feet tall (to the roof peak). A graveled parking area for employees, visitors, and equipment would be located adjacent to the building. The entire area would be fenced and have a locked gate.

1.4.1.5 Water Supply and Wastewater

During construction of the proposed Project, approximately 1.7 million gallons of water would be consumed for road compaction, dust control, wetting concrete and other construction purposes. The construction contractor would supply water used during construction. Water needed for construction would be purchased by the Applicant’s construction contractor from an off-site vendor with a valid water right and transported to the site in water-tanker trucks.

The Project would not be connected to a sewer system. Sanitary wastes would be collected in portable toilets during construction. Disposal of sanitary wastes would be managed through a contract with a portable toilet vendor. The contractor would incorporate applicable state capacity requirements based on the construction worker population on the Project Area at any given time. Collected wastes would be managed and disposed of by the contracted vendor.
Project operations would not require the use of any water for cooling or any other use aside from the limited needs of the Operations and Maintenance facility. Potable water intake would be in the form of a well accommodating the Operations and Maintenance facility’s needs. The Applicant would seek and obtain approval for the new well from EFSEC, in consultation with Skamania County Environmental Health Department and Ecology.

There would be no industrial wastewater stream from operation of the Project. Wastewater discharge would come from the Operations and Maintenance facility discharging to an on-site septic system. Less than 5,000 gallons per day is anticipated for kitchen and bathroom use. No wastewater would be used, discharged, or recycled for wind turbine operations.

**1.4.1.6 Site Access for Construction and Operation**

From State Route (SR) 14, access would be provided via county roads (Cook-Underwood Road to Willard Road) and then via a new connection to West Pit Road, an existing private logging road that connects to a network of existing logging roads on the Project Area.

Because the Project Area already has a network of logging roads, relatively few new roads would have to be constructed. Approximately 7.9 miles of existing private logging roads would be improved. In areas where there are no existing logging roads near proposed wind turbine strings, approximately 2.4 miles of new gravel access roads would be constructed. All new roadway construction would occur on private lands.

In addition to the permanent access roads described above, temporary access may be required to construct some facilities. For example, constructing the underground collector cables would require that heavy equipment be able to access trench locations where they are not directly adjacent to roads. Generally, equipment would be driven across open ground to accomplish this construction. In some locations minor grading may be required to allow safe access to construction locations (that would be determined only after final pole locations have been selected). These temporary access roads would be re-graded and re-seeded as necessary to restore vegetation after the construction phase is over.

After the Project is constructed, use of the improved and new access roads on private lands would be limited to use by the landowner and Project maintenance staff.

**1.4.2 NO ACTION ALTERNATIVE**

Under the No Action Alternative, the state of Washington would deny the Applicant’s application for a Site Certificate for the proposed Whistling Ridge Energy Project, and/or BPA would not grant interconnection of the Project to the FCRTS. As a result, the proposed Whistling Ridge Energy Project would not be constructed or operated under the No Action Alternative. This alternative would not help utilities seeking renewable energy resources in states with RPSs, such as Washington, Oregon, and California, in achieving the renewable energy goals mandated by each state’s RPS. Furthermore, this alternative would not help to meet the region’s need for additional power in coming years. If the proposed Project is not constructed, it is likely that this need would be addressed by some combination of energy efficiency and conservation measures, existing power generation sources, and/or the development of other new renewable and non-renewable generation sources.
In addition, it is reasonable to expect that under the No Action Alternative, the proposed Project Area would continue to be used for logging and other timber harvest activities. This site has been in commercial forestry use for the last century, during which the site has been logged over a series of approximately 50-year logging rotations. If the proposed wind project is not approved and built, the Applicant and others would continue to use the site for commercial forestry production. Ongoing timber management activities within the Project Area under this alternative would include regular tree clearing, harvesting, replanting, and development of additional access roads as necessary.

1.4.3 ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

The Applicant has proposed a particular type of generation facility (wind) at a specific site. The lead agencies, Washington EFSEC and BPA, must respond to the Applicant’s requests for authorizations and approvals for the proposed Project at this site. While this EIS focuses on the alternatives of either granting or not granting the Applicant’s requests, various other alternatives to the Proposed Action described in Section 1.4.1 also have been considered. These alternatives include alternate locations for the proposed Project, different Project sizes, alternative wind generation technologies, and different Project configurations. For potential alternatives, the Applicant identified a number of criteria that needed to be met in order for the Applicant to have a technically and economically feasible project suitable for further consideration. These criteria are as follows:

- The Project must be located in an area with a steady supply of robust wind power, and on a site on which construction could reasonably occur (no significant geotechnical constraints);
- To reduce startup costs, the Project must be located on land the Applicant owns and controls, and land that could serve a dual purpose of commercial forestry and power production;
- To allow the power to reach urban markets and eliminate the cost and time required to construct new transmission lines, the Project must be located in proximity to existing high-voltage transmission lines;
- The costs of construction must be outweighed by the potential return on investment, thereby requiring a minimum number of potential megawatts to be achieved by the Project; and
- The Project output must be at a competitive price and of adequate supply to be attractive to utilities looking to fulfill their Renewable and Alternative Energy Portfolio Standards.

The following discussion describes alternatives that were considered but eliminated from detailed study in this EIS because of technical or economic feasibility issues, not meeting the identified purpose of and need for the proposed action, or clearly greater environmental impacts:
1.4.3.1 Alternative Project Locations

The Applicant owns and manages 70,000 acres of timberland in Washington and Oregon. The Applicant manages its forestlands with the objective of producing as much high quality wood as possible, without compromising the future economic and environmental benefits of their forests. In reviewing its lands for location of a wind project, the Applicant sought:

- Areas of Applicant-owned property found to have a steady source of robust wind;
- Applicant-owned land that contained high ridges on which to place wind turbines with little impact to the continued underlying use of the land for commercial forestry;
- Land in proximity to existing high voltage transmission lines.

No other sites were identified that were under the ownership of the Applicant or as close to existing transmission infrastructure facilities as the proposed Project Area.

1.4.3.2 Larger or Smaller Generation Facility Size

During the Project planning process, the Applicant considered the feasibility of constructing and operating a larger generation facility, both in terms of more wind turbines and a larger Project Area, involving the proposed. Regarding more turbines, the site does contain a series of ridge lines that are conducive to locating wind turbines but at the same time are limiting as to where those turbines could be placed. In general, placement of turbines in areas substantially below the ridge lines would not effectively make use of the wind resource within the Project Area, thereby compromising the economic feasibility of the proposed Project. Accordingly, the constrained topography has necessitated a restricted generation facility power plant design.

Regarding a larger Project Area, the proposed Project is located on land situated between the Columbia River Gorge National Scenic Area on the south and land owned by the Washington State Department of Natural Resources (DNR) on the north. Land to the east and west was not considered, as those lands are at a lower elevation and do not include the north-trending ridge lines that exist on the proposed Project Area. While the Applicant did not consider locating turbines within the Scenic Area due to its sensitivities, consideration was given to locating turbines on the DNR lands directly north of the site. These lands have topographical characteristics similar to the proposed Project Area, and also have been logged through commercial forestry activities. However, use of these lands for Project turbines was rejected from further consideration due to comments from the public and DNR’s own reluctance to consider leasing the site to the Applicant.

The Applicant also considered the feasibility of a smaller generation facility within the proposed Project Area, either by removing turbines or utilizing a smaller Project Area. However, the Project is being proposed as an “integrated whole”—in other words, as a single generation facility, not pieces of a whole, where some turbines may be eliminated. The proposed Project includes a defined energy output, based on site and design characteristics, market demand, and Applicant objectives. These objectives include providing a minimum level of generation to be attractive to utilities seeking to fulfill their RPS requirements, as well as providing a return on investment to the Applicant. In order to provide this return, the Applicant has determined that the Project must be capable of producing a minimum of 70 MW. The number of wind turbines
within the Project Area already has been minimized to the extent practicable in light of the Applicant’s objectives. Accordingly, if any turbines are removed from the Project design, other locations must be found to replace those turbines to maintain the minimum necessary capacity. The constrained site location and topography limits the ability to relocate turbines within the Project Area.

In sum, the Project size was selected to optimize Project energy output and economic feasibility. A smaller wind turbine facility would be unlikely to offset Project development costs. A larger project would require additional infrastructure capacity and transmission capacity.

### 1.4.3.3 Alternative Wind Generation Technologies

Alternative technologies for the generation of power from a wind resource were considered. Several types of wind energy conversion technologies have been developed over the past three decades and include 1) vertical axis Darrieus wind turbines, 2) two-bladed downwind wind turbines, 3) smaller three-bladed upwind wind turbines (500 to 750 kilowatt [kW]), and 4) larger 3-bladed upwind wind turbines (1 to 3 MW). The three-bladed, upwind, horizontal axis is currently the preferred technology, based on proven reliability and commercial viability.

### 1.4.3.4 Alternative Project Configurations

As discussed above, the proposed Project Area contains a series of ridge lines that are conducive to locating wind turbines, but at the same time are limiting as to where those turbines could be placed. This means that there are limited options for locating wind turbines within the Project Area. Alternative turbine configurations were considered, but were eliminated from further study because they either did not appropriately utilize the wind resource present within the Project Area or compromised the economic feasibility of the proposed Project.

### 1.4.3.5 Alternative Interconnections

Alternatives for interconnecting the proposed wind Project with the existing high voltage transmission lines that currently cross the Project Area were considered. Initially, an option of interconnecting at a point within the Project Area directly east of the currently proposed interconnection point was identified. This alternative interconnection point was located between structures 22/6 and 23/1 on the North Bonneville-Midway 230-kV transmission line. However, this option would have required the development of interconnection facilities within the Columbia River Gorge National Scenic Area because structure 22/6 is on the border of, and structure 23/1 is within, the Scenic Area. Given the high sensitivity of the Scenic Area, construction of an interconnection alternative within its boundaries was eliminated from further study in this EIS.

An alternative interconnection also was considered outside the Project Area, approximately 1.5 miles west of the currently proposed interconnection point. BPA’s transmission engineers identified a potential alternative interconnection site between structures 21/4 and 22/1 on the North Bonneville-Midway 230-kV transmission line. This site is located in a relatively flat, lower-elevation area that may have easier access in the winter than the currently proposed interconnection site. However, this alternative would have required the Applicant to construct and operate a new 1.5 mile section of 230-kV transmission line from the proposed Project to this
Development of such a new line would have required the clearing of an approximately 125-foot-wide right-of-way corridor for the line, as well as the clearing and construction of additional new transmission line access roads. The Applicant also has stated that the additional costs of constructing this new line likely would make the Project no longer economically viable. Because of the much greater potential for environmental effects as compared to merely developing the currently proposed interconnection within the already planned Project Area, as well as the significant additional cost implications, this alternative was considered but eliminated from detailed study in this EIS.

An interconnection with the other existing BPA transmission line that crosses the Project Area also was considered but rejected from further study because the line is a 115-kV line and does not have sufficient capacity to transmit the energy from the Whistling Ridge Energy Project.

### 1.4.3.6 Alternative Access Roads

Finally, several alternatives for accessing the proposed Project Area were investigated. There are three potential ways to access the Project Area. All are via county roads from SR 14 to Cook-Underwood Road. In addition to the proposed access route from Cook-Underwood Road, which is included as part of the Proposed Action, the Project Area could be accessed by:

- **Route 1**: Ausplund Road to a private logging road vacated by Skamania County in 1987, which crosses private property (not owned by the Applicant) that is currently used for residential, agricultural orchards, and commercial timber production and harvest.

- **Route 2**: Kollock-Knapp Road to Scoggins Road to a private logging road called the CG2930 road on County Assessor’s maps, which crosses property owned by the Applicant that is currently used for commercial timber production and harvest.

The private logging road in Route 1 was made a County right-of-way in 1923. It was vacated for public use in 1987 by resolution of the Skamania Board of County Commissioners; however, the rights to use the road by abutting property owners remain. Additionally, road improvements to this route would be required for access to construct the wind energy facility and for ongoing Operations and Maintenance traffic. Impacts to a non-project landowner from these activities would occur if Route 1 were used. Therefore, Route 1 was eliminated as a construction roadway access alternative.

Route 2 would require minor roadway improvements that would not directly impact any non-project landowners. However, these roadway improvements would require construction within the Columbia River Gorge National Scenic Area. Therefore, Route 2 was eliminated as a construction roadway access alternative.

### 1.5 SUMMARY OF PUBLIC INVOLVEMENT, CONSULTATION, AND COORDINATION

#### 1.5.1 PUBLIC AND AGENCY SCOPING

Both SEPA and NEPA require opportunities for public involvement and comment during the preparation of an EIS. The initial phase of public involvement is the draft EIS “scoping” phase,
during which the lead agencies request public input on the scope of the draft EIS to be prepared, including the range of alternatives, potential environmental impacts, and possible mitigation measures. The lead agencies notify the public of the draft EIS scoping phase through various media (e.g., sending letters, publication notices, and internet postings), provide for a public scoping comment period, and hold public meetings to accept scoping comments. This section summarizes the public involvement and agency coordination activities that have been conducted to date for this EIS.

- **Initial EFSEC Public Notice.** On April 6, 2009, EFSEC mailed out a notice to the public concerning the Applicant’s March 10, 2009 Application for Site Certification Agreement for the Whistling Ridge Energy Project. Among other things, this notice included a summary of the proposed Project, a determination that an EIS was required, and information concerning the scoping process for the joint SEPA/NEPA EIS to be prepared by EFSEC and BPA. The notice also requested that all scoping comments be submitted by May 11, 2009 and provided the date, time, and location for the initial public information and scoping meeting for the EIS.

- **BPA Scoping Letter.** On April 17, 2009, BPA mailed a letter to agencies and individuals potentially interested in the proposed Whistling Ridge Energy Project that explained the proposal, BPA’s role, the EIS process including scoping, and how to participate. A comment sheet was included so interested parties could mail their comments to BPA. This letter also was posted on a BPA website created specifically for posting information and updates related to the EIS. BPA also provided advance notice to the State of Washington and appropriate tribes.

- **Revised EFSEC Public Notice.** On April 21, 2009, EFSEC issued a revised public notice that added announcing a second public information and scoping meeting for the EIS. This notice also extended the date for submitting scoping comments to May 18, 2009.

- **BPA Notice of Intent.** On April 21, 2009, BPA published a Notice of Intent (NOI) to prepare an EIS in the Federal Register. Like the BPA scoping letter, this NOI explained the proposal, BPA’s role and proposed action related to the proposal, the EIS process including scoping, and how to participate.

- **Agency Scoping Meeting.** An agency scoping meeting was held at the Rock Creek Center in the Skamania County Fairgrounds in Stevenson, Washington during the afternoon of May 6, 2009. The meeting was attended by representatives from EFSEC, BPA, the US Forest Service (USFS), the State Attorney General’s office (i.e., the Counsel for the Environment) and the general public. The primary agency comments received during the agency scoping meeting were provided by USFS.

- **First Public Information and EIS Scoping Meeting.** On May 6, 2009, EFSEC and BPA hosted an evening scoping meeting at the Rock Creek Center in the Skamania County Fairgrounds in Stevenson, Washington. The meeting included presentations by (1) EFSEC, explaining the process that would be followed during preparation of the EIS, (2) BPA on its role, and (3) the Applicant on the Project itself. Members of the public
asked questions and were given the opportunity to provide oral and written scoping comments on the scope and content of the EIS.

- **Second Public Informational and EIS Scoping Meeting.** On May 7, 2009, EFSEC hosted an afternoon scoping meeting at the Underwood Community Center in the community of Underwood, Washington. Similar to the May 6 meeting, the meeting included presentations by (1) EFSEC, explaining the process that will be followed for preparation of the EIS, (2) BPA on its role, and (3) the Applicant on the Project itself. Members of the public asked questions and were given the opportunity to provide oral and written scoping comments on the EIS.

- **Mailing List.** EFSEC and BPA have developed and maintained a mailing list of interested and affected parties for the EIS. All public notices and announcements concerning the Project have been mailed to all parties on the mailing list.

- **EIS Scoping Report.** Following closure of the public scoping comment period on May 18, 2009, EFSEC and BPA jointly reviewed all of the comments received from the public, tribes, public agencies, interest groups, and other parties and developed the scope of issues to be evaluated in the EIS. An EIS Scoping Report was prepared by EFSEC, in consultation with BPA, and made publicly available on August 25, 2009.

EIS scoping comments were received both at the EIS scoping meetings and through written submittals. A total of 122 people attended the two scoping meetings, and 79 speakers provided verbal comments. By the close of the comment period, a total of 421 EIS scoping letters or e-mails had been received from public agencies, tribes, environmental organizations, interested citizens, and others. Fifty-one of these submittals were duplicate letters or cover letters/e-mails attached to supporting documentation that did not include substantive comments. A total of 1,803 individual comments from the remaining 370 submittals were identified for consideration in this EIS. The EIS Scoping Report, which is incorporated by reference, provides additional information on the EIS scoping comments that were received.

1.5.2 **AGENCY CONSULTATIONS**

This section summarizes federal and Washington state statutes, implementing regulations, and Executive Orders requiring consultation, review, and/or permits or approvals. A complete listing of all Environmental Consultation, Review, and Permitting Requirements is provided in Section 4.0 of this EIS.

- **Endangered Species Act.** On June 8, 2010, BPA consulted with the U.S. Fish and Wildlife Service with the determination that the proposed Project may affect but is not likely to adversely affect northern spotted owl populations or critical habitat within the Project Area. On July 19, 2010, the U.S. Fish and Wildlife Service concurred with BPA’s findings under the Endangered Species Act, and provided comments on the draft EIS.

- **National Historic Preservation Act.** On August 2, 2010, BPA consulted with the Washington State Department of Archaeology and Historic Preservation (DAHP) regarding BPA’s Area of Potential Effects (APE) pursuant to BPA’s responsibilities
under Section 106 of the National Historic Preservation Act and 36 CFR 800. On August 9, 2010, BPA received concurrence for its APE from DAHP (Log No. 080910-26-BPA). BPA also initiated consultation with The Confederated Tribes of the Umatilla Indian Reservation, The Confederated Tribes of the Warm Springs Reservation of Oregon, The Nez Perce Tribe of Idaho, The Confederated Tribes and Bands of the Yakama Reservation, The Cowlitz Indian Tribe, and The Columbia River Inter-Tribal Fish Commission (CRITFC) pursuant to 36 CFR 800.4(a)(4) on August 2, 2010. On June 2, 2011, BPA submitted a cultural resources survey report to DAHP and interested Tribes (listed above) and determined that the federal undertaking should result in no historic or cultural properties affected.

- **Adjudicative Proceedings.** EFSEC has held adjudicative proceedings for the Whistling Ridge Energy Project under Chapter 34.05 RCW, the Administrative Procedure Act and commenced the adjudicative hearing related to Application No. 2009-01 in accordance with the procedural requirements found in Chapter 463-30 WAC and Chapter 34.05 RCW. For further information including motions, orders, and filings related to EFSEC adjudicative proceedings of the Whistling Ridge Energy Project, please see http://www.efsec.wa.gov/Whistling%20Ridge/Adjudication/wradj.shtml.

### 1.5.3 APPLICANT MEETINGS AND CONSULTATION

In addition to the EIS public scoping activities, the Applicant has been actively involved in meeting and consulting with local and state agency personnel and with Tribal leaders during the preparation of studies supporting the Application. The key contacts made by the Applicant to date are summarized in this section.

#### 1.5.3.1 Local Government

- **City of Bingen (January 2009).** Consulted with city administrator to obtain information stating that there are currently no load restrictions in place for Maple Street in the City of Bingen, Washington. Additional information was provided, stating that there is a significant increase in traffic volumes during the summer months due to recreational activities in the local area.

- **Klickitat County Public Works Department (January 2009).** Obtained the County “Resolution to Designate Haul Routes” document that could be used as a haul route agreement template for the Project by Skamania County. The document was forwarded to Skamania County for review.

- **Skamania County Planning Department.** Held three pre-application conferences between 2004 and 2008 with staff (including meetings on March 24, 2006 and August 22, 2007).

- **Skamania County Public Works Department.** Held pre-application meeting on August 22, 2007 with the County Road Engineer, and Building Inspector; meeting also attended by the Planning Department. In addition, the Skamania County Public Works Department Manager, the County Engineer, and the Maintenance Superintendent were
consulted to better understand existing roadway conditions, the proposed haul route, and traffic patterns. Meetings and consultation included:

- Meeting with Skamania County Public Utility District and Embarq, the local telephone service provider on utility availability

- A determination on weight restrictions for the tracks that cross Maple Street in the City of Bingen, Washington from the Burlington Northern Santa Fe Railroad

- Obtained average daily traffic on Cook-Underwood Road at approximately milepost 12 and location of the Cook-Underwood Road and Kollock-Knapp Road intersection at approximately milepost 10 to 10.5.

- Recommendation that right of way ownership and easements be determined early on in the planning process

- Requirement that both pre and post construction roadway inspections would need to be conducted along the haul route and that one additional roadway inspection would be required at one year post construction

- **Skamania County Assessor.** Conducted phone and office discussions regarding tax benefits to Skamania County from a potential wind energy project.

- **Skamania Economic Development Council.** Held various meetings and discussions regarding economic development and wind energy.

- **Skamania Public Utility District.** Met with Commissioners and General Manager regarding Skamania Public Utility District system vulnerability to interruption by BPA and benefits to be realized by a potential wind energy project in Skamania County.

- **Underwood Fire District.** Met with Fire Commissioners to discuss a service agreement for a potential wind energy project.

- **Mill A Volunteers.** Met with members to discuss the possible formation of a Fire District and inclusion of a potential wind energy project.

### 1.5.3.2 State Government

- **Washington Department of Archeology and Historic Preservation.** Conducted file search for historic and cultural properties within or near the Project Area.

- **Washington Department of Fish and Wildlife (WDFW).** Meetings with WDFW included:
  - February 26, 2004 meeting with WDFW and US Fish and Wildlife Service (USFWS) staff to discuss survey methods and results of wildlife surveys completed to date, and to discuss future surveys
- November 16, 2007 meeting and site tour to discuss survey methods and results of additional wildlife surveys completed to date.
- Several information exchanges with WDFW Area Habitat Biologist to discuss Project impacts, review survey results, and discuss survey protocols.
- Several follow-up meetings with WDFW staff during June, July and August of 2009 to continue the discussion and consultation on wildlife.
- Meeting with WDFW staff on December 8, 2009 to review results of wildlife surveys.

- **Washington State Department of Natural Resources.** Held a meeting and discussions with DNR staff regarding application to lease adjoining DNR property for wind energy purposes.

- **Washington State Department of Transportation, Goldendale Office.** Discussed information relating to over-size and over-weight vehicles traveling on SR 14. They stated that the current prohibition for loads in excess of 125 feet (including the trailer and load) between mileposts 19.00 and 83.53 could be overruled for trucks traveling between the SDS facility and the junction of SR 14 and Cook-Underwood Road. The Goldendale office must be contacted prior to any over-size hauls. Pilot cars would be required and Washington State Patrol involvement may be required.

- **Washington State Department of Transportation, Southwest Region Office.** Discussed information relating to road and bridge restrictions for over-size and over-weight motor vehicles traveling on SR 14 and over-size and over-weight load permit requirements.

### 1.5.3.3 Federal Government

- **U.S. Army Corps of Engineers at Bonneville Dam (January 2009).** Obtained information on lockage length and width parameters as well as average daily usage numbers for the months of May through October.

- **US Fish and Wildlife Service.** Meetings with USFWS included:
  - February 26, 2004 meeting with USFWS and WDFW staff to discuss survey methods and results of wildlife surveys completed to date, and to discuss future surveys.
  - Ongoing consultation with USFWS staff to discuss survey work and results.

### 1.5.3.4 Tribal Government

- Letter sent to Yakama Nation Cultural Resources Department.
- Site tour and consultation with local Tribes of Yakama Nation (see Section 3.10).
- Communication with Yakama Nation Cultural Resources Program concerning consultation and survey assistance.
1.5.3.5 Railroad

- **Burlington Northern Santa Fe Railroad.** Transportation Technology Services provided rail car length, width, and weight parameters as well as transport restrictions between the Port of Longview and the SDS facility.

1.5.4 DRAFT EIS COMMENT PERIOD AND PUBLIC MEETINGS

After completion of the draft EIS, EFSEC and BPA established a minimum 45-day comment period and distributed the draft EIS document for public comment and review. The comment period was later extended. During the comment period, the public had the opportunity to review and submit comments on the draft EIS to EFSEC and BPA both in writing and at two public meetings. EFSEC and BPA then prepared this final EIS that considers and responds to these comments and makes any necessary corrections or revisions to the EIS text. Responses to comments are presented in Appendix G.

This section summarizes the public involvement and agency coordination activities that have been conducted since the release of the draft EIS.

- On May 25, 2010, EFSEC and BPA sent out a letter to interested parties announcing the release of the draft EIS. This letter was also posted on a BPA website created specifically for posting information and updates related to the EIS.

- On May 28, 2010, the draft EIS was filed with the U.S. Environmental Protection Agency which published a Notice of Availability of the draft EIS to the Federal Register (volume 75, number 103).

- On June 16, 2010, EFSEC and BPA hosted a public meeting at the Underwood Community Center in the community of Underwood, Washington. On June 17, 2010, EFSEC and BPA hosted a second public meeting at the Rock Creek Center in the Skamania County Fairgrounds in Stevenson, Washington. These meetings were held to accept public comments on the draft EIS.

- The initial close of comment period for the draft EIS was July 19, 2010. EFSEC and BPA extended the comment period for comments to the draft EIS to August 27, 2010.

1.6 SUMMARY OF POTENTIAL PROJECT IMPACTS AND MITIGATION MEASURES

Table 1-2 summarizes the potential impacts, design measures, and mitigation measures to be implemented by the Project. This table is organized by the various elements of the environment. For each element, the potential impacts of the alternatives are summarized. Specific design measures that would reduce or eliminate impacts to which the Applicant has committed are also listed, as are other mitigation measures that have been identified.
Table 1-1  
Summary of Environmental Consequences and Design and Mitigation Measures

<table>
<thead>
<tr>
<th>Element of the Environment</th>
<th>Impact of Proposed Project: Construction and Operation of Facility, Transmission Interconnection, and Access Road</th>
<th>Impact of Alternate Operations and Maintenance Facility on West Pit Road</th>
<th>Impact of No Action Alternative</th>
<th>Design and Mitigation Measures</th>
</tr>
</thead>
</table>
| Earth                     | Construction:                                                                                               | Same potential impact levels as for proposed Project with the exception that the site identified for the alternative, Operations and Maintenance facility on West Pit Road is at a lower elevation and is a more level site so erosion potential may be less. | Existing potential for erosion from logging operations would continue. | Construction:  
  - A detailed geotechnical investigation would be performed to identify any subsurface conditions.  
  - A Construction SWPPP would be submitted for EFSEC approval and would include measures to control erosion.  
  - Foundations and building would be designed for Seismic Zone 2.  
Operation:  
  - Erosion and Sedimentation Control Plan, Environmental Protection Control Plan, and Stormwater Pollution Prevention Plan would be submitted to EFSEC for approval, and all would include BMPs to minimize erosion.  
  - Visual inspection would be conducted following any seismic activity to look for incipient mass movement. Adverse effects on wind turbines from ash fall would be mitigated through appropriate design. |
|                           | Operation:                                                                                                  |                                                                  |                                |                                |
|                           | Construction:                                                                                               |                                                                  |                                |                                |
|                           | Air Quality                                                                                                 |                                                                  |                                |                                |
|                           | Construction:                                                                                               |                                                                  |                                |                                |
|                           | Operation:                                                                                                  |                                                                  |                                |                                |
|                           | Construction:                                                                                               |                                                                  |                                |                                |
|                           | Operation:                                                                                                  |                                                                  |                                |                                |

Existing potential for fugitive dust and emissions would continue from logging operations.  
Construction of fossil-fuel power plants to meet regional demand could impact air quality through releases of SO2, NO, CO2 and other pollutants.  
Construction:  
- All vehicles used during construction would comply with applicable Federal and state air quality regulations.  
- Operational measures such as limiting engine idling time and shutting down equipment when not in use.  
- Active dust suppression on unpaved construction access roads, parking areas and staging areas, using water-based dust suppression materials in compliance with state and local regulations.  
- Dust control program to minimize any potential disturbance from construction-related dust. Dust suppression would be accomplished through application of either water or a water-based, environmentally safe dust palliative such as lignin.  
- Traffic speeds on unpaved Project roads would be kept to 25 mph to minimize dust generation.  
- Corring dusting of construction workers would be encouraged.  
- Disturbed areas would be replanted or graveled to reduce wind-blow dust.  
- Erosion control measures would be implemented to limit deposition of silt to roadways.  
- Temporary rock crushers or concrete batch plants would be required to submit a Notice of Construction to the Southwest Clean Air Agency and to comply with all permit requirements.  
Operation  
- Limit traffic speed on unpaved roads to 25 MPH to minimize dust from operation and maintenance vehicles.  

Temporary exhaust emissions from construction vehicles and equipment.  
Temporary odors from diesel equipment and vehicles.  
Temporary dust from construction operations.  

Temporary dust and emissions from Operations and Maintenance vehicles.  
Avoided emissions from fossil fuel power plants, including of greenhouse gasses and other pollutants.  

Impact would be the same as for the construction and operation of the Operations and Maintenance facility located within the Project Area.  

- Limit traffic speed on unpaved roads to 25 MPH to minimize dust from operation and maintenance vehicles.  

Existing potential for erosion from logging operations would continue.  
Construction:  
- A detailed geotechnical investigation would be performed to identify any subsurface conditions.  
- A Construction SWPPP would be submitted for EFSEC approval and would include measures to control erosion.  
- Foundations and building would be designed for Seismic Zone 2.  
Operation:  
- Erosion and Sedimentation Control Plan, Environmental Protection Control Plan, and Stormwater Pollution Prevention Plan would be submitted to EFSEC for approval, and all would include BMPs to minimize erosion.  
- Visual inspection would be conducted following any seismic activity to look for incipient mass movement. Adverse effects on wind turbines from ash fall would be mitigated through appropriate design.  

Existing potential for fugitive dust and emissions would continue from logging operations.  
Construction of fossil-fuel power plants to meet regional demand could impact air quality through releases of SO2, NO, CO2 and other pollutants.  
Construction:

| Water                      |                                                                                                             | Impact would be the same as for the construction and operation of the Operations and Maintenance facility located within the Project Area. | Existing patterns of ground and surface water use and impacts would continue. | Construction:  
  - Discharge of stormwater runoff from the Project would be regulated by EFSEC, based on Ecology’s stormwater pollution control program.  
  - EFSEC may require the Project to obtain coverage under the Construction Stormwater General Permit, since it would disturb more than 1 acre of land.  
  - Final design would conform to the applicable Ecology Stormwater Management Manual in effect at the time or as instructed by EFSEC.  
  - Unless it is instructed by EFSEC that it is not necessary to do so, the Applicant would file an NOI to obtain coverage under the Construction Stormwater General Permit and the Industrial Stormwater General Permit.  
  - Applicant has committed to design and implement the same BMPs as required in Ecology’s permits.  
  - Site-specific BMPs for temporary erosion and sedimentation control during construction would be identified on the construction plans submitted to EFSEC.  
  - Site-specific BMPs for temporary erosion and sedimentation control during construction would be identified on the construction plans submitted to EFSEC.  
  - Operational BMPs would be adopted as part of the SWPPP to implement good housekeeping, preventive and corrective maintenance procedures, slow for spill prevention and emergency cleanup, employee training programs, and inspection and record. |
| Operation                  |                                                                                                             | Impact would be the same as for the construction and operation of the Operations and Maintenance facility located within the Project Area. | Existing patterns of ground and surface water use and impacts would continue. | Construction:  
  - Permanent stormwater management requires construction of appropriate stormwater hydraulic and treatment facilities, routine maintenance thereof, and prevention of chemical pollution through source control.  
  - The constructed permanent stormwater BMPs would include:  
    - Vegetated drainage ditches,  
    - Culverts with stabilized inlets and outlets,  
    - Permanent erosion and sedimentation control through site landscaping, grass, and other vegetative cover,  
    - Runoff treatment BMPs would be designed to conform to the applicable Stormwater Management Manual.  
  - Due to the small area of impervious surface in the Project Area, no detention storage is required.  
  - Operational BMPs would be adopted as part of the SWPPP to implement good housekeeping, preventive and corrective maintenance procedures, slow for spill prevention and emergency cleanup, employee training programs, and inspection and record. |

<tr>
<td>Biological Resources</td>
<td>Construction</td>
<td>Impact would be the same as for the construction and operation of the Operations and Maintenance facility located within the Project Area.</td>
<td>• Existing pattern of habitat fragmentation from logging would continue.</td>
<td>Design Features Include:</td>
</tr>
<tr>
<td></td>
<td>• Temporary impact to approximately 53.6 acres of grass/forb, brush/field/shrub, conifer-hardwood forest and conifer forest habitat.</td>
<td></td>
<td>• Other power generation facilities, including other wind projects or generation using fossil fuels, could be constructed and operated in this region to meet long-term needs for power.</td>
<td>• Micrositing of turbines and associated facilities would allow any sensitive resources discovered during construction to be avoided.</td>
</tr>
<tr>
<td></td>
<td>• Temporary impact to approximately 60.7 acres of grass/forb, brush/field/shrub, conifer-hardwood forest and conifer forest habitat.</td>
<td></td>
<td>• Potential impacts from creation of fossil fuel power plants.</td>
<td>• Avoiding and minimizing the use of overhead collector lines which create areas where birds may congregate and perch, thus decreasing the potential for turbine collisions.</td>
</tr>
<tr>
<td></td>
<td>• Potential loss of suitable habitat, potential fatalities during clearing or grading of the construction area, and disturbance/displacement from construction activity and personnel occupying the site.</td>
<td></td>
<td>• hairstyles mortality to some birds and bats due to turbine collision and displacement. Though not in sufficient quantities to affect population viability.</td>
<td>• Use of tubular turbine towers, avoiding the lattice type towers which create areas where birds may congregate and perch thus decreasing the potential for turbine collisions.</td>
</tr>
<tr>
<td></td>
<td>• Potential mortality to birds through nest disturbance during clearing for turbine strings and new roads.</td>
<td></td>
<td>• No impacts to listed species.</td>
<td>• Use of un-guyed meteorological towers, reducing the potential for bird collision with wires.</td>
</tr>
<tr>
<td></td>
<td>Operation</td>
<td>The proposed Project would result in mortality to some birds and bats due to turbine collision and displacement. Through not in sufficient quantities to affect population viability.</td>
<td>• No impacts to listed species.</td>
<td>• Minimization of turbine lighting in the Project Area, thereby reducing the potential for birds and bats to be disoriented by lights or attracted to turbines.</td>
</tr>
<tr>
<td></td>
<td>• There would likely be some. The proposed Project would result in mortality to some birds and bats due to turbine collision and displacement. Through not in sufficient quantities to affect population viability.</td>
<td>• No impacts to listed species.</td>
<td>• Installation of newer generation up-wind turbines.</td>
<td>• As per the WDWP/Wind Power Guidelines, compilation of extensive pre-project assessment of wildlife, habitat and plants in the Project Area, including review of existing information and databases, habitat mapping, general avian use surveys, bat surveys, and surveys for threatened or endangered species.</td>
</tr>
<tr>
<td></td>
<td>• Use of certified “weed free” straw bales during construction to avoid introduction of noxious weeds.</td>
<td>• No impacts to listed species.</td>
<td>• Use of certificated “weed free” straw bales during construction to avoid introduction of noxious weeds.</td>
<td>• Construction of a noxious weed control program, in coordination with the Skamania County Noxious Weed Control Board, to control the spread and prevent the introduction of noxious weed species.</td>
</tr>
<tr>
<td></td>
<td>• All temporarily disturbed areas would be reseeded with an appropriate mix of native plant species as soon as possible after construction is completed to accelerate the revegetation of these areas and to avoid the establishment and spread of noxious weed species.</td>
<td>• All temporarily disturbed areas would be reseeded with an appropriate mix of native plant species as soon as possible after construction is completed to accelerate the revegetation of these areas and to avoid the establishment and spread of noxious weed species.</td>
<td>• Implementation of a noxious weed control program, in coordination with the Skamania County Noxious Weed Control Board, to control the spread and prevent the introduction of noxious weed species.</td>
<td>• In order to avoid or minimize impacts to any raptors potentially nesting in or near the Project Area, a raptor nest survey would be conducted during the breeding season, approximately April to July, prior to construction activities that would remove forest cover and/or require heavy equipment substantial enough to potentially disturb nesting activities.</td>
</tr>
<tr>
<td></td>
<td>• Implementation of a noxious weed control program, in coordination with the Skamania County Noxious Weed Control Board, to control the spread and prevent the introduction of noxious weed species.</td>
<td>• Implementation of a noxious weed control program, in coordination with the Skamania County Noxious Weed Control Board, to control the spread and prevent the introduction of noxious weed species.</td>
<td>• In order to avoid or minimize impacts to any raptors potentially nesting in or near the Project Area, a raptor nest survey would be conducted during the breeding season, approximately April to July, prior to construction activities that would remove forest cover and/or require heavy equipment substantial enough to potentially disturb nesting activities.</td>

</thead>
</table>
| Energy and Natural Resources | Construction  
Construction of the Project would require approximately:  
- 97,290 gallons of fuel (diesel and gasoline) for construction equipment,  
- 3,700 tons of steel for turbine towers,  
- 1,000 tons of steel for tower foundation reinforcement,  
- 100,000 yards of gravel (aggregate) for roads and crane pads,  
- 10,000 cubic yards of concrete for turbine foundations,  
- 1.7 million gallons of water for road compaction, dust control, wetting concrete, etc., assuming plain water is used for dust control (this amount could be reduced through the use of lignin or other dust palliative if permitted by EFSEC).  
Operation  
- Fuel for Operation and Maintenance vehicles (approximately 8,500 gallons annually).  
- Minor quantities of lubricating oils, greases and hydraulic fluids for the wind turbine generators (less than five 50-gallon drums).  
Impact would be the same as for the construction and operation of the Operations and Maintenance facility located within the Project Area. | | | • Convene a Technical Advisory Committee to evaluate the mitigation and monitoring program and determine the need for further studies or mitigation measures. The Technical Advisory Committee would be composed of representatives from WDFW, USFWS, Skamania County, and the Applicant. The role of the Technical Advisory Committee would be to coordinate appropriate mitigation measures, monitor impacts to wildlife and habitat, and address issues that arise regarding wildlife impacts during construction and operation of the Project, including potential adaptive management opportunities. The post-construction monitoring plan would be developed in coordination with the Technical Advisory Committee.  
- For potential impacts to big game species (deer and elk), coordination with WDFW would occur if appropriate.  
- Prepare a SWPPP for both the construction and operation phases of the Project, and submit to EFSEC for approval.  
- Coordinate and consult with BPA to ensure that any potential impacts to fish are prevented, as part of the interconnection agreement.  
Operation  
- Prepare and follow a post-construction monitoring plan (developed in coordination with the Technical Advisory Committee described above).  
- Implement a two year minimum post-construction avian mortality study.  
- Prepare a SWPPP for both the construction and operation phases of the Project, and submit to EFSEC for approval. | • Energy and water use for the Operations and Maintenance facility would not take place.  
• Base load demand would likely be filled through expansion of existing, or development of new, thermal generation such as gas-fired combustion turbine technology. Other wind sources could also be developed. | • Adverse impacts to energy and natural resources are expected to be minimal and therefore no mitigation measures would be required. |
### Table 1-1 (Continued)
#### Summary of Environmental Consequences and Design and Mitigation Measures

<th>Impact of Alternate Operations and Maintenance Facility on West Pit Road</th>
<th>Impact of No Action Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Public Health and Safety</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Environmental Health</td>
<td>• Electricity for Project operations (less than approximately 600 kilowatt hours per wind turbine generator per month).</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Water for use at the Operations and Maintenance facility and periodic maintenance of turbine blades (less than 5,000 gsd).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Construction</td>
<td>• Project construction could temporarily increase the risk of fire in the Project Area as a result of the operation of vehicles and power equipment, which may cause fires through contact with dried plants during dry summer weather.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Blasting may be used where solid rock is encountered during construction of turbine foundations or trenches for the underground electrical collection system. Blasting could also create a fire hazard during dry weather.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The risk of releases to the environment that would impact health would be similar to any large construction project. The primary potentially hazardous materials used during construction would be diesel fuels, lubricating oils, hydraulic fluids, and mineral oil.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Vandalism of Project facilities and theft of equipment may occur during construction.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Project construction could lead to a slight increase in the chance of traffic accidents, due to the presence of a peak of 265 construction workers traveling to the site, along with the transport of construction materials and the turbine components. This impact would last a maximum of one year, with peak impacts limited to a several-month period in the summer.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The risk of turbine structural failure during construction would be very small.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Operation</strong></td>
<td>• Turbine fires are possible, however with the types of modern wind turbines proposed for the Project, turbine malfunctions leading to fires in the nacelle are extremely rare.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Operation of the Project would not result in the generation of regulated quantities of hazardous wastes. Since no fuel would be burned to power the wind turbine generators, there would be no spent fuel, ash, sludge or other process wastes generated. The only materials used during Project operations that present any potential for accidental spills are lubricating oils and hydraulic fluids used in the wind turbine generators and transformers.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Vandalism of Project facilities and theft of equipment during operation is similar to that expected during construction.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The risk of traffic accidents during operation would be low.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Structural failure of the turbine tower is very rare, though some instances of turbine failure have been documented in older turbine models.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Design and Mitigation Measures

- A Transportation Management Plan (TMP) that would direct and oblige the contractor to implement procedures to minimize traffic impacts would be prepared in consultation with both WADOT and Skamania County and submitted to EFSEC for approval.

<th>Impact of Alternate Operations and Maintenance Facility on West PR Road</th>
<th>Impact of No Action Alternative</th>
<th>Design and Mitigation Measures</th>
</tr>
</thead>
<tbody>
<tr>
<td>Noise</td>
<td>Construction</td>
<td>• Cases of blade throw are rare and have generally been linked to improper assembly or exceedance of design limits. • The risk of impacts from ice throw is minimal. • At a distance beyond 2,500 feet, shadow flicker is considered to be imperceptible. Even if shadow flicker were a proven impact, none of the planned turbines are within 2,500 feet of existing residences. • EMF from the Project would be lower than those of many common household appliances and would have no proven health and safety impacts.</td>
<td>• Existing sound levels from the site vicinity include timber harvest activities, agricultural activities, which would continue in the future with or without the Proposed Action. No known noise impacts currently occur from these agricultural activities, and none would be anticipated to occur in the future.</td>
<td>• Construction would generally occur only during daytime hours to reduce the potential for noise impacts. • All noise-producing Project equipment and vehicles using internal combustion engines would be equipped with mufflers, air-inlet silencers where appropriate, and any other shrouds, shields, or other noise-reducing features. • Mobile or fixed &quot;package&quot; equipment (e.g., arc-welders, air compressors) would be equipped with shrouds and noise control features. • All mobile or fixed noise-producing equipment used on the project that is regulated for noise output by a local, state, or federal agency, would comply with such regulation while in the course of project activity. • The use of noise-producing signals, including horns, whistles, electronic alarms, sirens, and bells, would be for safety warning purposes only. • Unless required for such safety purposes, and as allowable by applicable regulations, no construction-related public address, loudspeaker, or music system would be audible at any adjacent noise-sensitive land use. • The construction contractor would implement a noise complaint process and hotline number for the surrounding community. • The Applicant would have the responsibility and authority to receive and resolve noise complaints.</td>
</tr>
<tr>
<td></td>
<td>Operation</td>
<td>• Construction noise at the three closest residential properties is anticipated to be between 65 and 72 decibels. • The large distances between much of the Project Area and potentially affected residences, the temporary nature of construction, and the restriction of construction activities to daytime hours would serve to minimize potential noise impacts from construction activities. Based on the anticipated noise levels and the timing aspects of these impacts, construction noise impacts are expected to be low.</td>
<td>• During Project operations, nighttime noise levels are anticipated to increase from existing 34 dBA to 38 – 39 dBA at Receiver 1, from existing 35 dBA to 40 dBA at Receiver 2, and from existing 35 dBA to 41 - 43 dBA at Receiver 3. Daytime noise levels are anticipated to increase from existing 38 dBA to 40 – 43 dBA. • Because predicted Project operation sound pressure levels at the nearest noise-sensitive receivers are at least 7 dBA lower than the 50 dBA L eq compliance threshold, none of these above conditions is expected to result in the Project operation exceeding noise regulations. • Modern turbine designs have been modified to reduce or eliminate low frequency sound. • Recent studies performed for the Canadian Wind Energy Association have described usage of 85-90 dBG as a criterion for human perception of infrasound and, by reasonable extension, the likely threshold for infrasound complaint. The horizontal distances of the Project wind turbines to the nearest noise-sensitive receivers are at least 915 meters, which provides sufficient attenuation to offset the amount of decibels that one might add to account for the quantity of wind turbines of the Project. Thus, the expected infrasound at the nearest existing receivers (R1 and R2) would remain under an estimated value of 70 dBG, which is 15 dBG less than the previously stated criteria.</td>
<td>• Noise impacts from construction and operating the Operations and Maintenance Facility on West PR Road, as compared to the facility located within the Project Area, would be higher due to the closer proximity to residences west of the Project Area. Noise levels are anticipated to be below state and local standards.</td>
</tr>
<tr>

| **Land Use and Recreation** | Construction  
- Construction-related noise and dust could temporarily affect nearby homes and businesses located along the site access route, though this impact would not be sufficient to change existing land use patterns.  
- Construction activities could impact some recreation users through temporary increases to traffic, and from construction-related dust and noise, such as users of the Underwood Park and Community Center located along Cook-Underwood Road. These impacts would be temporary and are expected to be minor.  
- Operation  
- Operation of the Project would not cause changes to existing land uses or land use activities or development patterns.  
- Operation of the facility would not result in a sufficient increase in population or traffic to impact local recreational facilities.  
- The only potential impact of the Project to recreation resources, including users of the Columbia River Gorge National Scenic Area (CRGNSA), would be the minor to moderate impacts to the visual experience of visitors in some locations discussed in Section 3.9 Visual Resources.  
- The Project would not impact any Wild and Scenic Rivers. | For the Operations and Maintenance facility located at the West Pit site, earth movement and construction-related traffic would generate slightly more noise and dust along West Pit Road over anticipated levels for roadway construction without the facility. The additional noise and dust could temporarily affect nearby homes along Willard Road. Other impacts are anticipated to be similar for both alternative locations.  
- The existing pattern of land use would continue, including the use of the Project Area for commercial forestry and the surrounding area for commercial forestry, agriculture and rural residences.  
- No substantial impacts to land use are anticipated, and no mitigation measures are required. The only potential impact to recreation users from operation would be the minor to moderate impact to visual resources from some viewpoints. As discussed in Section 3.9 Visual Resources, the primary mitigation measure proposed is to paint the turbines and blades a flat grey color to decrease visibility. | No mitigation measures are proposed during construction.  
- No mitigation measures are required. The only potential impact to recreation users from operation would be the minor to moderate impact to visual resources from some viewpoints. As discussed in Section 3.9 Visual Resources, the primary mitigation measure proposed is to paint the turbines and blades a flat grey color to decrease visibility. |  
| **Visual Resources** | Construction  
- Large earth-moving equipment, trucks, cranes, and other heavy equipment would be visible from some nearby areas.  
- At times, small, localized clouds of dust created by road building and other grading activities may be visible at the site.  
- In close-up views, the construction activities would be highly visible and would have a moderate to high visual impact. From more distant locations, the visual effects of construction would be relatively minor and would have little or no impact on the quality of views.  
- Construction impacts would be short-term, lasting no more than the one-year construction period.  
- Operation  
- The turbines would be visible from some viewpoints, including some within the CRGNSA. The Project has the potential to create low to moderate levels of visual impact at key viewpoints.  
- The Project would be required to comply with Federal Aviation Administration’s (FAA) aircraft safety lighting requirements for structures greater than 200 feet tall, which includes turbines and meteorological towers. The exact number of turbines that would require lighting would be specified by the FAA after it has reviewed final Project plans. These lights would be visible as | The alternative site at West Pit Road would be more visible to local traffic but would not cause a substantial visual impact.  
- The existing visual landscape would continue, including openings in tree cover from clear cutting and agricultural operations.  
- Construction  
- The turbines would be painted a non-reflective flat neutral grey or light color to minimize visual impacts.  
- Lights typically used to meet Federal Aviation Administration requirements would to some extent be shielded from ground level view due to a constrained (3–5 degree) vertical beam. The Federal Aviation Administration would independently review the lighting of individual turbines during the micrositing process and consult on mitigation. However, the Project must comply with the safety lighting requirement. |

| **Historic and Cultural Resources** | Construction  
- Potential impact to the remnants of the Haran Farmstead through ground disturbance during construction of the new Project road and turbine and transformer pads along Turbine String D. The degree of impact would depend on the final location of the road and turbines. This site has been recommended as ineligible for nomination to the National Register of Historic Places (NRHP).  
- Potential impacts to other, currently undiscovered cultural or historic resources. Based on the extensive inventories conducted, the likelihood of encountering additional sites is low.  
- Potential impact to Yakama Indian Nation Traditional Cultural Property (TCP) within the Applicant’s Area of Proposed Effect (APE) from the proposed Project.  
- Operation  
- Ongoing maintenance of the road along Turbine String D has the potential to cause additional impact to the Haran Farmstead site or other, currently undiscovered resources. | No historic or cultural resources are anticipated at the alternative site at West Pit Road. | The current potential for disturbance to undiscovered cultural resources from logging operations would continue. | Construction  
- The primary mitigation method for construction impacts to the Haran Farmstead site would be to locate the new road for Turbine String D and the turbine and transformer pads at sufficient distance from the Haran Farmstead site so that impacts would not occur.  
- The Haran Farmstead is confirmed as ineligible for nomination to the NRHP, no mitigation would be required.  
- Potentially impacted sites would be the current levels of service and the use of the Project Area roads for commercial timber harvest.  
- Improvements to County and private roads between SR 14 and the project area would be necessary to support the long and heavy loads that would be required for the delivery of the wind energy components. The specific improvements required would depend primarily upon truck size, load size, and axle loading.  
- New roadway construction would be required for access to all proposed wind tower locations. In addition to approximately 7.9 miles of existing private logging roads that would require improvement, approximately 2.4 miles of new private gravel access roads would need to be built.  
- Temporary construction equipment such as cranes and derricks that would be used for the construction of the proposed towers could pose a hazard to aviation safety during the construction period. A “Determination of No Hazard to Air Navigation” would need to be obtained for the proposed Project Area.  
- Project construction would last approximately one year. During that time, there would be an increase in traffic activity in and around the Project Area due to the construction workforce, equipment deliveries, and empty trucks returning to SR 14. | Transportation  
- Construction

#### Summary of Environmental Consequences and Design and Mitigation Measures

<table>
<thead>
<tr>
<th>Element of the Environment</th>
<th>Impact of Proposed Project: Construction and Operation of Facility, Transmission Interconnection, and Access Road</th>
<th>Impact of Alternate Operations and Maintenance Facility on West PR Road</th>
<th>Impact of No Action Alternative</th>
<th>Design and Mitigation Measures</th>
</tr>
</thead>
</table>
| Construction and Operation of Facility, Transmission Interconnection, and Access Road | • The impact of Project construction on local schools would be at most minor and temporary, as few out-of-area construction workers are likely to be accompanied by families for this temporary construction project.  
  • Construction-related impacts to local utilities providing telephone, electric or solid waste pickup are also expected to be minor and temporary. Most workers would not be in the area for long enough to obtain these services; those who stayed in temporary housing in the area would not remain for more than a few months.  
  • The presence of construction vehicles on area roads would not impact the response times for emergency providers. Construction trucks would represent additional volume on area roads, but transportation LOS would remain at LOS A or B (delays of less than 15 seconds), and thus would not cause substantial delays to emergency response vehicles. |  |  | construction to reduce the potential need for increased police services to the Project Area. Provisions could include temporary fencing with a locked gate around the construction site, the use of site trailers for the temporary storage of special equipment or materials, and the use of outdoor lighting and motion-sensor lighting.  
  • Emergency plans would be prepared to protect the public health, safety, and environment on and off the Project Area in the case of a major natural disaster or industrial accident relating to or affecting the Project.  
  • The construction specifications would require that the contractors prepare and implement a Construction Health and Safety Program that included an emergency plan. The Construction Health and Safety Program would include the following provisions:  
    • Construction Injury and Illness Prevention Plan,  
    • Construction Written Safety Program,  
    • Construction Personnel Protective Devices,  
    • Construction Onsite Fire Suppression Prevention,  
    • Construction Offsite Fire Suppression Support. |  |  |  |
| Operation | • Operation of the Project would create a potential positive impact to public services and utilities. The Project’s assessed value could be as much as $87.5 million, and this would generate approximately $180,000 per year in tax distributions to municipal, county and other local jurisdictions. Although impacts are expected to be minimal, a portion of these funds could nevertheless be used to upgrade existing public services and utilities in Klickitat County.  
  • The Project would have eight to nine on-site employees during operation. Given this small number, and considering the use of on-site services and emergency response plans, the Project is expected to have minimal adverse impact on local public services and utilities. |  |  |  |
| Fire protection | • The construction manager would be responsible for staying abreast of fire conditions in the Project Area by contacting DNR and implementing any necessary fire precautions.  
  • A Fire Protection and Prevention Plan would be developed for EFSEC approval and implemented, in coordination with the Skamania County Fire Marshall and appropriate agencies.  
  • Both the wind turbine generators and the substation would be equipped with lightning protection systems.  
  • All onsite operations employees would be responsible for contributing to ongoing fire prevention in the Project Area through the following programs:  
    • Operational Safety Program,  
    • Operations Written Safety Program,  
    • Emergency Action Plan,  
    • Emergency Action Plan. |  |  |  |

<td>In addition, the Applicant would:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Provide detailed maps that show all access roads to the Project.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Provide keys to a master lock system that would enable emergency personnel to unlock gates that would otherwise limit access to the Project.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Use spark arresters on all power equipment, e.g., cutting torches and cutting tools</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Inform workers in the Project Area of emergency contact phone numbers and train them in emergency response procedures</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Carry fire extinguishers in all maintenance vehicles</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Coordinate with DNR when the fire danger is high</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Comply with equipment rules and regulations required by DNR for work conducted in wildland/forested lands</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Construction and Operation</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>During both construction and operation, fire risk would be mitigated through BMPs including:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• All on-site service vehicles fitted with fire extinguishers.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Fire station boxes with shovels, water tank sprayers, etc. installed at multiple locations on site along roadways during summer fire season.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Minimum of one water truck with sprayers must be present on each turbine string road with construction activities during fire season.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• No gas powered vehicles allowed outside of graveled areas.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Use of high clearance vehicles on site if used off-road.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Smoking restricted to designated areas (outdoor gravel covered areas).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Soil Blasting would be conducted by state licensed explosive specialist contractors. Explosives require special detonation equipment with safety lockouts.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Clear vegetation from the general footprint area surrounding the excavation zone to be blasted.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Standby water spray trucks and fire suppression equipment to be present during blasting activities.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• All major construction equipment used is to be diesel powered (i.e. w/o catalytic convertors).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Specialty engineered lightning protection and grounding systems used at wind turbines and at substation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Footprint areas around turbines and substations would be graveled with no vegetation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Generators not allowed to operate on open grass areas.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• All portable generators to be fitted with spark arrestors on exhaust system.</td>

</thead>
<tbody>
<tr>
<td>Socioeconomics</td>
<td>Impact would be the same as for the construction and operation of the Operations and Maintenance facility located within the Project Area.</td>
<td>Current patterns of employment and housing would continue, including the reliance on the agricultural and timber economy for employment.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Construction</td>
<td>• Indirect and induced value added from construction is estimated to be approximately $3.9 million. Also, Project construction would result in 71 indirect and induced jobs.</td>
<td>• No mitigation measures would be required.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The local area contains sufficient temporary housing for out-of-area construction labor, and the Project is not expected to impact housing values, rents or new home starts.</td>
<td>• Construction contractors would be required to advertise positions locally and to employ local workers to the greatest extent possible.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Fiscal impacts are expected to be positive, with a total $150 M in construction expenditures, of which approximately $13.2 M would be spent in the local area. Most sales tax revenue would go to Skamania County.</td>
<td>• Construction contractors would be required to advertise positions locally and to employ local workers to the greatest extent possible.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Construction is not expected to impact property values or property tax revenues.</td>
<td>• Construction contractors would be required to advertise positions locally and to employ local workers to the greatest extent possible.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Economic impacts would be positive due to increased tax revenues, employment and local expenditures.</td>
<td>• Construction contractors would be required to advertise positions locally and to employ local workers to the greatest extent possible.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Sales, use and other indirect business taxes to state and local governments attributable to Project operation are estimated at approximately $90,000 per year.</td>
<td>• Construction contractors would be required to advertise positions locally and to employ local workers to the greatest extent possible.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The proposed Project would have an estimated value of $87.5 million, which would represent an increase of 6.5 percent in assessed value in the County. At current tax rates, the increase in property tax revenue to the County would be $731,500 annually.</td>
<td>• Construction contractors would be required to advertise positions locally and to employ local workers to the greatest extent possible.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The Project would employ eight to nine employees; most would be hired from the local area. This work force would not impact local housing supply or prices.</td>
<td>• Construction contractors would be required to advertise positions locally and to employ local workers to the greatest extent possible.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Based on a review of available studies, operation of the Project is not expected to create adverse impact to property values.</td>
<td>• Construction contractors would be required to advertise positions locally and to employ local workers to the greatest extent possible.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
1.7 SUMMARY OF UNAVOIDABLE ADVERSE IMPACTS

Table 1-3 summarizes the potential unavoidable adverse impacts remaining after application of mitigation measures.

<table>
<thead>
<tr>
<th>Element of the Environment</th>
<th>Unavoidable Adverse Impacts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Earth</td>
<td>The primary unavoidable impacts are the potential for landslide and erosion. Both can be mitigated through appropriate design and the application of mitigation measures.</td>
</tr>
<tr>
<td>Air Quality</td>
<td>The proposed Project would produce minor impacts to air quality, similar to existing logging operations. By producing electricity without generating air emissions, the Project would contribute to a beneficial impact on overall air quality.</td>
</tr>
<tr>
<td>Water</td>
<td>Construction and operation of the Project would only result in negligible to minor impacts to water resources because the impacts are localized and the disturbance is short-term.</td>
</tr>
<tr>
<td>Biological Resources</td>
<td>The Project would result in the permanent loss of approximately 60.7 acres of habitat which would be converted to new Project roads, turbines and pads, substation and Operations and Maintenance facility. These impacts, while unavoidable, would take place in a landscape of managed timber lands which has for many years and will continue to be a fragmented environment with ongoing disturbance. During construction, direct mortality to birds could occur through nest disturbance. The Project would result in some ongoing mortality to birds and bats through turbine collisions. This level is not expected to be high enough to impact species viability. The Project is unlikely to cause mortality to any threatened or endangered species.</td>
</tr>
<tr>
<td>Energy and Natural Resources</td>
<td>The Project would have minor unavoidable adverse impacts to energy or natural resources. The overall impact of the Project to energy and natural resources would likely be positive, since it would provide the region with low-cost, clean, renewable energy, in accordance with state and national policies and priorities.</td>
</tr>
<tr>
<td>Public Health and Safety</td>
<td>Unavoidable adverse impacts to environmental public health and safety are anticipated to be minimal. Unlike thermal power plants, wind power projects pose a much smaller risk of explosion or fire potential, as there is no need to transport, store, or combust fuel to generate power. The risk of unintentional or accidental fire or explosion or discharge to the environment during both construction and operations would be minimal. The risk of accidents during construction would be no higher than for any large construction project and would be minimized through standard construction safety requirements and procedures. The risk of accidents during operation would be minimal.</td>
</tr>
</tbody>
</table>
1.0 Summary and Purpose of and Need for Action

1.8 CUMULATIVE IMPACTS

Cumulative impacts are the incremental impacts of a proposal when considered in the context of other past, present and reasonably foreseeable future actions. Cumulative impacts can result
from individually minor but collectively significant actions taking place over time. This section summarizes the information contained in Section 3.14.

1.8.1 PROJECTS CONSIDERED

1.8.1.1 Existing Development

The general Project vicinity is characterized by agriculture, commercial forestry, rural residential development, and a small number of commercial enterprises. The proposed Project Area is located in the state of Washington approximately two miles north of the Columbia River and directly north of the Columbia River Gorge National Scenic Area. The National Scenic Area extends along the Columbia River for about 85 miles and includes 292,500 acres in parts of three Oregon and three Washington counties. Although both the Project Area and the proposed access road are located completely outside the National Scenic Area, the proposed Project Area does extend south to its northern boundary. The Gifford Pinchot National Forest is located north of the Project Area.

On both the Washington and Oregon sides of the Columbia River, land use is predominantly commercial forestry and residential in numerous small, unincorporated communities. There is some limited agriculture located within the National Scenic Area. South of the Scenic Area, on the Oregon side, land uses include commercial forestry, agriculture, and some residential.

Portions of the Whistling Ridge Energy Project would be visible to drivers along I-84, located on the Oregon side of the Columbia River. For the purpose of assessing cumulative impacts to visual resources, views of other wind projects from I-84 were considered. From Cascade Locks, Oregon (located southwest of the Project Area on the Oregon side of the Columbia River) to the intersection with I-82 which leads north to the Tri-Cities, I-84 extends for a distance of approximately 127 miles. Along this segment, there are 18 existing wind power generation projects, all located within a distance of approximately 70 miles east of the Whistling Ridge Energy Project site (to approximately Arlington, Oregon).¹ Eighteen projects could potentially be viewed by drivers travelling along I-84 within a driving time of approximately one to one-and-one-half hours and were included in the analysis of cumulative impacts to visual resources described in Section 3.14.

1.8.1.2 Reasonably foreseeable Future Development

Reasonably foreseeable future development generally includes those actions currently underway, formally proposed or planned, or highly likely to occur based on available information. Reasonably foreseeable future development projects located within approximately 20 miles of the Project Area were identified to determine if they could potentially have cumulative impacts on the environment, including water quality, soil erosion, vegetation, terrestrial wildlife species, and bird and bat species. Projects were identified through searches of the web sites of Skamania, Klickitat and Hood River Counties, Columbia River Gorge Commission, Washington State

¹ See map at http://www.nwcouncil.org/maps/power/Default.asp.
Department of Transportation (WSDOT), Oregon Department of Transportation, EFSEC, the Oregon Department of Energy, and the Ports of Skamania County, Klickitat County, The Dalles, and Cascade Locks.

Both non-wind and wind reasonably foreseeable future projects were initially considered for inclusion in the cumulative impact analysis. Non-wind projects involved transportation improvements, communications facilities, and power line improvements. Of these projects, only the Oregon Department of Transportation bridge replacement projects, now in progress along I-84, were considered close enough to the Project Area to be included in the cumulative impact analysis. The other transportation, communication, and power line improvement projects were considered to be too far from the Whistling Ridge Project Area to result in cumulative impacts and were therefore eliminated from further analysis. Reasonably foreseeable wind projects are shown in Figure 3.14-1. Of these projects all except the Middle Mountain Project were judged to be too far away (generally more than 20 miles) from the Whistling Ridge Energy Project site to result in cumulative impacts. Nonetheless, the cumulative visual resource impact analysis does consider reasonably foreseeable wind projects within approximately the same geographic area as existing wind projects considered in that analysis. In addition, the cumulative impact analysis has been updated to reflect the discontinuation of the Middle Mountain Project. The Middle Mountain Project, originally proposed by Hood River County as a small community scale wind project of around 10 MW, would have been located on the south side of the Columbia River, approximately 17 miles south of the Whistling Ridge Energy Project. However, on May 17, 2010, the Hood River County Commission decided to discontinue efforts to develop the Middle Mountain wind project and this project therefore has been removed from the cumulative impact analysis. Therefore, the only reasonably foreseeable development projects included in the cumulative impact analysis are the Oregon Department of Transportation bridge replacement projects along I-84.

The remaining six projects included transportation improvements, communications facilities, and power line improvements. Of these, only the Oregon Department of Transportation bridge replacements now in progress along I-84 were considered close enough to the project area to be included in the cumulative impact analysis. The other five transportation, communication, and power line improvement projects were considered to be too far from the Whistling Ridge project site to result in cumulative impacts.

Thus, the Middle Mountain Wind Project and the I-84 Bridge Replacement Project are the only two reasonably foreseeable future projects with a potential for cumulative impacts with the Whistling Ridge Energy Project. These two projects were analyzed in addition to the visual impacts of the ten existing wind projects.
1.8.2 RESULTS OF CUMULATIVE IMPACTS ANALYSIS

The cumulative effects of the Proposed Action, in combination with other the past, present, and reasonably foreseeable future actions (identified above) would have on the various environmental resources are discussed in Section 3.14 of this EIS. Cumulative impacts from the combination of these actions could occur for each of the environmental resources. However, the contribution of the Proposed Action to these cumulative impacts would vary, with the greatest contribution occurring in cumulative impacts on visual resources as constructing and operating the Whistling Ridge Energy Project would add a view of an additional wind power project to travelers in the Gorge. In addition to the existing and reasonably foreseeable future projects east of the Project Area, long-distance travelers in either direction along I-84 could see some elements of the Whistling Ridge Project, for approximately 12.5 miles traveling west and 6.5 miles traveling east. Travelers along SR 14 would not see the Proposed Action, which would be blocked by the bluff to the north of the road. As discussed in more depth below in Section 3.14.3.10, the visual impact of the Whistling Ridge Project along I-84 would be variable, with the number of turbine strings visible changing with topography. In many places only a few turbines would be visible, and the area where the most turbines would be visible (directly across the Columbia River from White Salmon and Bingen) would also be the area where the viewer would be the farthest from the Project Area (See Figure 3.9-1). This would constitute a small cumulative impact when considered in combination with views of other wind projects located from 35 to 70 miles to the east.

The proposed action would contribute incrementally, though in a minor way, on cumulative impacts to soil erosion and water quality in the Project Area, as well as to vegetation, terrestrial wildlife species, and bird and bat species in the region. Low levels of adverse cumulative impacts have also been identified for energy and natural resources from the use of steel, concrete and vehicle fuel for construction, and for transportation (traffic safety and increased risk of accidents during construction periods of the Whistling Ridge Energy Project and the I-84 bridge replacement projects, if they should overlap). Simultaneous construction projects may create a beneficial cumulative socioeconomic impact to local communities. Finally, by introducing up to 75 MW of clean renewable energy into the regional electrical grid, the Project would positively contribute to efforts to combat the cumulative impacts of climate change, and also contribute to efforts to improve air quality in the Columbia River Gorge vicinity.

1.9 ORGANIZATION OF THIS EIS

Much of the organization of this document is based on the SEPA EIS format and content specified in WAC 197-11-430 and 197-11-440, with adjustments made to ensure NEPA compliance as well. The remainder of this EIS is organized as follows:

- **Chapter 2, Proposed Action and Alternatives.** Chapter 2 describes the Proposed Action and alternatives, including the No Action Alternative and alternatives to elements of the proposed Project evaluated in the EIS.

- **Chapter 3, Affected Environment, Impacts, and Mitigation.** Chapter 3 describes the existing environment without construction and operation of the Whistling Ridge Energy Project for each environmental resource. The chapter also includes analyses of the
environmental effects of constructing and operating the Whistling Ridge Energy Project and determines whether there is the potential for environmental impacts to occur for each environmental resource. If impacts could occur, they are evaluated to determine if they could be avoided. Mitigation measures to lessen or eliminate impacts also are listed as well as a section describing cumulative impacts for each environmental resource.

- **Chapter 4, Environmental Consultation, Review and Permitting Requirements.** This chapter describes the permits and approvals that must be obtained for the construction and operation of the Whistling Ridge Energy Project.

- **Chapter 5, Distribution List.** This chapter lists individuals and organizations that have received a copy of the Draft EIS.

- **Chapter 6, List of Preparers.** This chapter lists the individuals who contributed to the preparation of this EIS. It also includes their organization affiliation and a brief description of their professional backgrounds.

- **Chapter 7, Index.** This chapter contains an index for the EIS

- **Appendices.** The appendices provide supporting technical information to the EIS.
  - Appendix A: Application for Site Certification, as amended October 12, 2009;
  - Appendix B: Geotechnical Report;
  - Appendix C: Wildlife Reports;
  - Appendix D: Land Use Consistency Determination;
  - Appendix E: Agency Consultations
  - Appendix F: Consultant Disclosure Statements
  - Appendix G: Response to Comments
  - Appendix H: Comment Letters

1.10 REFERENCES

2.0 PROPOSED ACTION AND ALTERNATIVES

This chapter describes the Proposed Action, the No Action Alternative, and alternatives that were considered but eliminated from detailed study. This chapter also discusses the benefits or disadvantages of reserving Project approval for a later date, and provides a summary comparison of the alternatives.

The Proposed Action involves responding to requests from the Applicant for approvals of the Whistling Ridge Energy Project. Whistling Ridge Energy LLC is a limited liability corporation operating in the State of Washington that has been formed by S.D.S. Co., LLC, which is an affiliated entity of SDS. Under the Proposed Action, the state of Washington would approve the Applicant’s application for a Site Certificate for the proposed Whistling Ridge Energy Project, and BPA would grant interconnection of the proposed Project to the Federal Columbia River Transmission System (FCRTS). Under the No Action Alternative, the state of Washington would deny the Applicant’s application for a Site Certificate for the proposed Project, and/or BPA would not grant interconnection of the Whistling Ridge Energy Project to the FCRTS.

2.1 PROPOSED ACTION

This section describes the wind Project that has been proposed by the Applicant. The information presented in this section is primarily based on information provided by the Applicant in the Application for Site Certification Agreement (Application 2009-01) submitted to EFSEC on March 10, 2009, and amended on October 12, 2009 (Appendix A).

2.1.1 WIND POWER IN GENERAL

Wind power is a form of renewable energy - energy that is replenished daily by the sun. As the earth is heated by the sun, air rushes to fill the low pressure areas, creating wind power. The wind is slowed dramatically by friction as it brushes the ground and vegetation, so it may not feel very windy at ground level. The kinetic power in the wind, the energy of moving air molecules, may be five times greater at the height of a 40-story building (the height of the blade tip on a utility-scale wind turbine) than the breeze on your face. Meanwhile, the wind may be accelerated by certain types of land forms, so that certain areas of the country may be very windy while other areas are relatively calm.

Wind power is converted to electricity by a wind turbine. In a typical, utility-scale wind turbine, the kinetic energy in the wind is converted to rotational motion by the rotor—typically a three-bladed assembly at the front of the wind turbine. The rotor turns a shaft that transfers the motion into the nacelle (the large housing at the top of a wind turbine tower). Inside the nacelle, the slowly rotating shaft enters a gearbox that greatly increases the rotational shaft speed. The output (high-speed) shaft is connected to a generator that converts the rotational movement into electricity at medium voltage (a few hundred volts). The electricity flows down heavy electric cables inside the tower to a transformer, which increases the voltage of the electric power to distribution-level voltage (a few thousand volts). This distribution-level voltage power flows through underground lines to a collection point where the power may be combined with other wind turbines.
In some cases, the electricity generated by these wind turbines is sent directly to nearby farms, residences and towns where it is used. In most cases, however, the distribution-level voltage power is sent to a substation where the voltage is increased to transmission-level voltage power (a few hundred thousand volts) and sent through transmission lines many miles to distant cities and factories (AWEA 2007).

2.1.2 PROJECT OVERVIEW

The proposed Whistling Ridge Energy Project would be located in south-central Washington on an approximately 1,152-acre site approximately 7 miles northwest of the City of White Salmon in Skamania County, Washington (Figure 1-1). The Project would be located on commercial forestland owned by the Applicant in an unincorporated area of Skamania County, outside of the Columbia River Gorge National Scenic Area.

The proposed Project would generate up to 75 MW of electricity. The proposed Project layout is shown in Figure 2-1. As shown in this figure, Project components would include:

- Up to **50 wind turbines ranging from** 1.2 to 2.5 MW **in generating capacity**;
- Electrical transformers;
- 34.5-kV collector lines and systems (primarily underground);
- A Project collector substation located adjacent to BPA’s proposed substation and to BPA’s existing North Bonneville-Midway 230-kV transmission line;
- An interconnection with BPA’s existing North Bonneville-Midway 230-kV transmission line;
- One Operations and Maintenance facility (to be located at one of two locations, either adjacent to the substation within the Project boundary, or along West Pit Road);
- One permanent meteorological tower; and
- Approximately 2.4 miles of newly-constructed **roads** and 7.9 miles of improved roads to provide access to the wind turbine locations during construction and for operations and maintenance.

As shown in Figure 2-1, the proposed wind turbines generally would be located on the forested ridges of Saddleback Mountain. The final specific locations of the wind turbines and other related and supporting facilities would be established during the final design process, taking into account micro-siting aspects determined as a result of detailed geotechnical investigations and the EFSEC Site Certification process. As shown in Table 2-1, approximately 384 acres would be developed for the wind turbine foundations, connecting roadways, and overhead and underground transmission lines.

a Project Area is the area shown on Figure 2-1 bordered in black, encompassing approximately 1,152 acres in Sections 5, 6, 7, 8, and 18 of Township 3 North, Range 10 East, and in Section 13 of Township 3 North, Range 9 East.
b Wind Facility footprint is the total area of all corridors and development study areas in the Project boundary with overlapping areas removed, in which development potentially could take place.
c Total area of 650-foot corridor measured on either side of an imaginary line connecting each turbine in a string. Permanent impacts based on turbine clearance zone and permanent infrastructure in corridor but outside of clearance zone. Temporary impacts based on infrastructure in corridor but outside clearance zone.
d Area encompassed by a 100-foot corridor along all roads within the Project Area minus any area that overlaps with 650-foot-wide turbine corridor, based on a roadway length of 7.8 miles.
e Total area encompassed by a 100-foot corridor along all roads within the Project Area minus any area that overlaps with roadway, overhead or turbine string corridors.
f Area includes the 2-acre Operations and Maintenance site plus a 50-foot area around the perimeter.
g Area includes the 5-acre substation site plus a 50-foot area around the perimeter.
h Area based on 40-foot corridor (20-foot roadway; 12-foot existing, widened to 20 feet with 10 feet on either side) from Project Area boundary to an intersect point with Willard Road, based on a length of 2.5 miles.

County and private logging roads that extend north from SR 14 provide vehicle access to the Project Area. From SR 14, access would be provided via County roads (Cook-Underwood Road to Willard Road) and then via a new connection to West Pit Road, an existing private logging road. West Pit Road connects to a network of existing private logging roads (Figure 2-1). The private logging roads are on S.D.S. Co., LLC and Broughton Lumber Company property, and provide access to most areas where Project facilities would be located.

The construction phase is anticipated to last approximately one year, during which a total of approximately 330 workers would be employed. Eight to nine permanent full- or part-time Operations and Maintenance staff would be required should the Project become operational. The Whistling Ridge Energy Project is expected to function for at least 30 years.
2.1.3 PROJECT COMPONENTS

2.1.3.1 Wind Turbines

The Project would consist of up to 50 wind turbines generators that likely would range in size from 1.2- to 2.5-MW each. Each wind turbine would consist of four main aboveground components: the turbine tower, the nacelle, the rotor hub, and the blades. Depending on which manufacturer is selected, each turbine would be approximately 221 to 262 feet tall at the turbine hub, and with the nacelle and blades mounted, the total height of each wind turbine (to the turbine blade tip) would be up to approximately 426 feet. The turbines throughout the Project would all be the same model, although height may vary in response to terrain. The towers would be tapered, hollow tubular structures, approximately 14 feet in diameter at the base and weighing approximately 30 tons each. The towers would likely be painted a flat neutral gray or white color. A controller cabinet would be located at the base inside each tower. Cables and a ladder would ascend to the nacelle to provide access for turbine maintenance. A locked door would provide access to the base of the tower.

Each tower would be mounted on a concrete foundation with a diameter up to approximately 60 feet. Tower foundations would be spread footing or pier-type footings. Some of the towers would be furnished with blinking lights visible to aircraft. The need for turbine lights and the type of lighting would be determined in consultation with the Federal Aviation Administration.

The remaining three turbine components are all mounted at the top of each turbine tower. The nacelle of each wind turbine is encased in fiberglass, and is mounted at the top of the tower to house the gearbox, the generator, and the control system. The rotor hub is attached to the nacelle, and holds the blades in place. Each turbine has three laminated fiberglass blades, each approximately 129 to 164 feet long, depending on which turbine is selected. The diameter of the circle swept by the rotors would be approximately 264 to 320 feet, depending on which turbine is selected. Together, each turbine’s blades, hub, and nacelle of each turbine would weigh between 95 and 150 tons, depending on the turbine size and model selected.

Wind turbines would be grouped in “strings,” each spaced approximately 350 to 800 feet from the next (or approximately 1.5 to 2.5 times the diameter of the turbine rotor). The electrical output of each string would be connected to the Project substation by underground 34.5-kV collector cables, and from there would be directly interconnected with the adjacent BPA transmission system. The Project would be monitored and controlled from an Operations and Maintenance building located at one of two alternative sites, either next to the substation or adjacent to West Pit Road.

The wind turbines would operate at wind speeds from 9 to 56 mph, with a rotor speed range of 10 to 20 rpm. The turbines operate on a variable pitch principal in which the rotor blades rotate to keep them at the optimum angle to maximize output for all wind speeds. At speeds exceeding 56 mph, the blades feather on their axis and the rotor stops turning. Each turbine is equipped with a wind vane that signals wind direction changes to the turbine’s electronic controller. The electronic controller operates electric motors (the yaw mechanism), which turn the nacelle and rotor so that each turbine faces into the wind.
2.1.3.2 Electrical Collector System

The Project would include an electrical collector system to collect energy generated at approximately 575 V from each wind turbine, transform the voltage of this energy to 34.5-kV using a pad-mounted transformer, and deliver the energy via underground cables to the proposed Project substation (Figure 2-1).

Each turbine’s 575 V to 34.5-kV transformer would be located on a transformer pad adjacent to each tower, or enclosed in the nacelle, depending on the turbine model. From there, power would be transmitted via underground 34.5-kV electric cables. These cables would be buried by digging trenches up to 5 feet wide and approximately 3 to 4 feet deep, placing the cables in these trenches, and then filling the trenches back in with the excavated soils. In areas where collector cables from several strings of turbines follow the same alignment (for example, near the proposed substation) multiple sets of cables would be installed within each trench where possible.

There would be approximately 8.5 miles of underground collector cable trenches. In areas where environmental constraints, geologic features, or cultural features necessitate, minor aboveground placement of collector cables may occur.

2.1.3.3 Project Substation and Interconnection

The Project would also include a collector substation to connect the proposed Project to the FCRTS. This substation would further transform the energy delivered by the Project’s underground electrical collector system from 34.5-kV to 230-kV so that it would be suitable for delivery to the FCRTS at the proposed BPA substation. The proposed electrical interconnection to the FCRTS would provide the Applicant with access to the wholesale electric market for sales of power from the proposed Project.

The proposed collector substation would occupy a portion of a fenced 5-acre area at the northwest end of the Project Area, immediately adjacent to BPA’s North Bonneville-Midway transmission line (Figure 2-1). A 50-foot cleared area would be maintained around the substation. The substation site would be a graveled, fenced area that would include the voltage transformers, switching equipment, and other electrical equipment, as well as an area to park utility vehicles. Transformers at the substation would be non-polychlorinated biphenyl oil-filled types.

The physical interconnection of the proposed Project to the FCRTS would consist of overhead lines located between the Project collector substation and BPA’s North Bonneville-Midway 230-kV transmission line. To make this interconnection, a loop-in of BPA’s North Bonneville-Midway 230-kV transmission line to the proposed BPA substation would be made. This loop-in would require several steel lattice and wood pole structures (some of the wood pole structures may be guyed) to be placed adjacent to both the North Bonneville-Midway 230-kV and Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines. The Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV line adjacent to North Bonneville-Midway 230-kV transmission line would require a new steel lattice structure to raise the conductors such that the 230-kV line could cross underneath for this interconnection.
2.1.3.4 Operations and Maintenance Facility

A permanent Operations and Maintenance facility would be constructed on an approximately 5-acre area located at one of the following two locations: (1) adjacent to the proposed substation; or (2) west of the Project Area along West Pit Road (Figure 2-1). The entire 5-acre area would be fenced and have a locked gate.

The Operations and Maintenance facility would have approximately 3,000 square feet of enclosed space, including office and workshop areas, a kitchen, bathroom, shower, and utility sink. This structure would be constructed of sheet metal, and would be approximately 16 feet tall (to the roof peak). Water for the bathroom and kitchen would come from a new on-site well and would drain into an on-site septic system (see Section 2.1.3.6). A graveled parking area for employees, visitors, and equipment would be located adjacent to the building.

2.1.3.5 Meteorological Tower

One permanent meteorological tower would be located within the Project Area. The function of the permanent meteorological tower would be to collect wind speed and direction information at hub height as well as temperature, relative humidity and barometric pressure. These values are used to provide base data to compare the function of the individual turbine wind direction and speed sensing equipment. The data collected by the tower also serves as a historical basis for measuring wind facility actual performance vs. projected performance.

The location for the permanent meteorological tower would be determined during the micro-siting process. The selected site would be based on a meteorologist’s recommendations for an on-site location that best represents the Project Area’s meteorological conditions.

The basic design for the tower would depend on the style selected. Most towers are un-guyed lattice towers at heights equal to the hub heights of the proposed wind turbines. Depending on the wind turbine selected for the Whistling Ridge Energy Project, the wind turbine would be approximately 221 to 262 feet high at the turbine hub. The meteorological towers are fairly large at the base with either three or four corners and taper in size up to hub height. Monitoring equipment would be located at the top, with the data logger and power conversion equipment located at the base.

2.1.3.6 Water Supply and Wastewater

During construction of the proposed Project, approximately 1.7 million gallons of water would be consumed for road compaction, dust control, wetting concrete and other construction purposes. The construction contractor would supply water used during construction. Water needed for construction would be purchased by the Applicant’s construction contractor from an off-site vendor with a valid water right and transported to the site in water-tanker trucks.

The Project would not be connected to a sewer system. Sanitary wastes would be collected in “portable toilets” during construction. Disposal of sanitary wastes would be managed through a contract with a portable toilet vendor. The contractor would incorporate applicable state capacity requirements based on the construction worker population in the Project Area at any given time. Collected wastes would be managed and disposed of by the contracted vendor.
Project operations would not require the use of any water for cooling or any other use aside from the limited needs of the Operations and Maintenance facility. Potable water intake would be in the form of a well accommodating the Operations and Maintenance facility’s needs. Anticipated water use at this facility is expected to be less than 5,000 gallons per day for kitchen and bathroom use. The Applicant would seek and obtain approval for the new well from EFSEC, in consultation with Skamania County Environmental Health Department and Ecology.

There would be no industrial wastewater stream from operation of the Project. Wastewater discharge would come from the Operations and Maintenance facility discharging to an on-site septic system. No wastewater would be used, discharged or recycled for wind turbine operations.

2.1.3.7 Access Roads

Access to the Project Area is provided by county and private logging roads that extend north from SR 14. From SR 14, access would be provided via County roads (Cook-Underwood Road to Willard Road) and then via a new connection to West Pit Road, an existing private dirt logging road that is located entirely outside of the National Scenic Area. Approximately 2.5 miles of roadway improvements would occur on West Pit Road, which currently varies in width between 20 and 26 feet. To create a drivable surface of 25 feet with 5 feet of clearing on each side, portions of the roadway and some corners would be widened. In addition, an existing culvert that runs along a portion of this road that was upgraded during the summer of 2009. This culvert may need some additional lengthening if the roadway is widened over the culvert. West Pit Road would continue to be used during the Project’s operational phase.

West Pit Road connects to a network of existing private logging roads on S.D.S. Co., LLC and Broughton Lumber Company property, and provides access to most areas where Project facilities would be located (Figure 2-1). Because the Project Area already has an existing network of logging roads, relatively few new roads would need to be constructed. Approximately 7.9 miles of existing private logging roads would be improved. In areas where there are no existing logging roads near proposed wind turbine strings, approximately 2.4 miles of new gravel access roads would be constructed. All new roadway construction would occur on private lands owned by S.D.S. Co., LLC and Broughton Lumber Company.

The existing logging roads to be improved were originally built to allow large trucks and logging equipment to access the Project Area for ongoing commercial logging purposes. These roads are generally 8 to 12 feet wide, although some are currently as wide as 20 feet. Improvements to allow use by Project construction vehicles generally would involve widening and providing a gravel all-weather surface. Most of the roads used to provide access to the site by construction vehicles would be widened to approximately 25 feet (width of finished road), with an additional 5 feet of shoulder on either side.

Once assembled, the construction cranes required to erect turbines and tower sections require a 35-foot-wide road (of which 25 feet needs to be graveled). Therefore, the roads that run adjacent to turbine strings and roads that connect turbine strings to one of the central staging areas would be approximately 35 feet wide (25 feet plus 5 feet of shoulder on either side). Because cranes might be needed to maintain turbines over their operational life, the 35-foot-wide roads would be kept as maintenance access roads for the expected 30-year life of the Project.
All private roadway improvements required prior to hauling, and new private roadway construction in the proposed Project Area, would be designed and constructed under the direction of a licensed engineer, in accordance with the standards for the applicable road classifications as set forth in the Skamania County Private Road Guidelines and Development Assistance Manual (Skamania County 2008), as adopted by the County Resolution in 2008. All existing county roadways requiring improvements prior to hauling would be designed and constructed in accordance with the WSDOT Design Manual (WSDOT 2007) and A Policy on Geometric Design of Highways and Streets (AASHTO 2004). A detailed geotechnical investigation of the specific locations of all Project elements would be conducted. If this investigation indicates the potential for slope instability at turbine sites or other Project facilities, such as access roads (including improvements to West Pit Road), these facilities would be redesigned or relocated to avoid this risk.

In constructing permanent access roads, a gravel surface would be installed, compacted to meet all equipment load requirements, and maintained to reduce wind erosion and dust. Existing culverts across intermittent streams would be replaced with wider or stronger culverts as necessary, and drainage improvements would be made (pursuant to a Project Erosion Control Plan and National Pollutant Discharge Elimination System [NPDES] permit), as necessary to control runoff.

In addition to the permanent access roads described above, temporary access may be required for constructing some facilities. For example, constructing the underground collector cables would require that heavy equipment be able to access trench locations where they are not directly adjacent to roads. Generally, equipment would be driven across open ground to accomplish this construction; in some locations minor grading may be required to allow safe access to construction locations (construction locations would be determined only after final tower locations have been selected). These temporary access roads would be re-graded and reseeded as necessary to restore vegetation after the construction phase is over.

After the Project is constructed, use of the improved and new access roads on private lands would be limited to the landowner and to Project maintenance staff.

2.1.4 PROJECT CONSTRUCTION

2.1.4.1 Construction Activities

Construction of the proposed Project is expected to take approximately one year, and would likely occur from early spring through late fall. Construction of the Project would involve the following tasks:

- Harvesting trees in areas that are not already cleared;
- Constructing roads and turbine crane pads;
- Constructing foundations for turbine and meteorological towers;
- Trenching for underground utilities;
• Placing underground electrical and communications cables in trenches;
• Constructing the Project substation;
• Constructing the Operations and Maintenance building;
• Transporting tower sections to the site and assembling towers;
• Transporting nacelle, rotor, and other turbine equipment to the site and installing the equipment on the assembled towers;
• Final testing; and
• Final road grading, final erosion control and site cleanup.

Staging and equipment lay-down areas would be used. These locations would be selected from sites that are accessible from existing roadways and are currently disturbed, or where disturbance could be minimized. Disturbances for staging and lay-down areas would be restored following construction.

In addition, the proposed transmission interconnection would be constructed between the Project substation and BPA’s existing North Bonneville-Midway transmission line, which passes through the Project Area. Access for construction of the interconnection would be via existing access roads for the BPA transmission line, which are currently used for periodic inspection and maintenance of that line. The construction sequence for the transmission interconnection would include the following activities:

• **Stringing Conductors/Static Wires.** Conductor stringing involves a sequence of running pilot lines through pre-positioned pulleys located on each tower. A truck-mounted, spooled conductor would then be positioned at the beginning of the segment to be strung. Take-up spools, also truck-mounted, would be located at the end of the segment to be installed. Pilot lines would be pulled through with tension maintained and the conductors would follow and be left in position on the towers. Installation would be completed by connecting the conductors to the individual insulators and adjusting the conductor sag between towers to predetermined dimensions. In some locations, static wires also would be installed for protection of the transmission line. The static wires would be installed in a manner similar to the conductors. The conductor stringing operation would primarily involve the movement of wheeled vehicles along the access road.

• **Site Cleanup.** Following construction of the interconnection, all residual construction debris would be removed and disturbed areas would be restored as required.

After the Project has been constructed, trees on most of the site would be allowed to mature on a normal forest management schedule (according to the Applicant staff, trees in the Project Area grow about 2 feet per year on average). Figure 2-2 shows the current forest types in the Project Area.
Figure 2-2

Current Forest Types

Source: GeoDataScape.

Whistling Ridge Energy Project
Skamania County, Washington
The exception would be in an area immediately surrounding the turbines and the access roads to the turbines. To allow for safe access to each tower for maintenance, to eliminate the potential for trees falling against the towers during storms, and for fire protection, an area extending approximately 150 feet from the center of each tower would be managed to maintain vegetation below approximately 15 feet in height. These dimensions may be adjusted during the final micrositing process to best balance the interest of maximizing electrical generation, along with maximizing replanting of all trees to ensure the best possible operation of the site for ongoing commercial forestry purposes.

2.1.4.2 Construction Schedule

Assuming that the state of Washington approves the Applicant’s application for a Site Certificate, and BPA grants the Applicant’s interconnection request, the Applicant would then begin construction of the proposed Whistling Ridge Energy Project. Actual construction activities, from groundbreaking to commercial operations, are expected to take approximately one year (15 months). Although actual timing of Project approvals needed to start construction are not precisely known at this time, the Applicant anticipates Project permitting with EFSEC to be completed by the fall or winter of 2011 by the end of 2010 or early 2011, with a Record of Decision (ROD) from BPA approving the requested interconnection being issued shortly thereafter. Under this schedule, the Applicant would conduct final Project engineering, equipment procurement, and contractor selection as early as the fourth quarter of 2011 and the first quarter of 2012. Project construction and pre-operational testing could begin as early as the second quarter of 2011 and conclude in the fourth quarter of 2012. If this schedule is met, the Applicant anticipates that the Whistling Ridge Energy Project would begin commercial power production by January 2013.

2.1.4.3 Construction Manpower and Truck Trips

The average size of the construction workforce would be about 110 workers, with a peak of approximately 265 workers in the seventh month of the construction period. Table 2-2 shows the approximate number of on-site construction workers by activity, which would vary month by month. Table 2-3 shows the on-site construction labor by month of construction.

Truck trips to and from the Whistling Ridge Energy Project for construction-related activities would average 30 trips during the AM peak hours and 10 trips during PM peak hours. During the peak month of construction activity (approximately eight months prior to commercial operation), traffic would increase to 390 vehicles along eastbound SR 14 at the east junction with Cook-Underwood Road.

---

2 “Micrositing” is process of choosing the wind turbine and their exact positions within the project area. Micrositing will occur after permit approvals are obtained and all permit conditions are known.

2.1.4.4 Construction Costs and Fiscal Considerations

The total estimated construction cost of the Whistling Ridge Energy Project would be approximately $150 million, which includes the wind turbines and associated equipment.

Construction of the proposed Project also would result in fiscal contributions within the three-county area of Skamania, Klickitat, and Hood River counties. These contributions are anticipated to be approximately $13.2 million, or just under 10 percent of the total estimated $150 million in construction costs. The $13.2 million would include supplies purchased from local suppliers, as well as increased sales tax revenues from purchases (such as food, gasoline, and lodging) made by construction workers. In addition, Skamania County would be expected to experience an increase in sales tax revenue of approximately $6,600 due to sales tax on the construction contract.

2.1.5 PROJECT OPERATION

Once operational, the Whistling Ridge Energy Project would operate 24 hours per day, seven days per week. Project operations would require eight to nine permanent full-time and/or part-time staff. Positions required for Project operation include those listed in Table 2-4.

<table>
<thead>
<tr>
<th>Staff Positions</th>
<th>Number of Operating Personnel</th>

<tr>
<td>Administrative Manager</td>
<td>1</td>
</tr>
<tr>
<td>Administration Assistant</td>
<td>1</td>
</tr>
<tr>
<td>Total</td>
<td>8 to 9</td>
</tr>
</tbody>
</table>

The annual cost of Project operation would be approximately $3.75 million. Of this annual amount, approximately $1.5 million would be for labor costs, such as wages and benefits for employees. The remaining $2.25 million in annual costs would include expenditures for materials, supplies, equipment, insurance, and contracted maintenance labor.

Operation of the proposed Project also would result in permanent fiscal contributions to the regional economy. Skamania County would be expected to experience an increase in annual property tax revenue of approximately $731,500 due to the increase in assessed value of the parcels on which the Whistling Ridge Energy Project would be constructed. This would represent an annual increase of 7.6 percent compared to the amount of property tax collected for these parcels in calendar year 2007.

2.1.6 FOREST HARVEST DURING PROJECT CONSTRUCTION AND OPERATION

The Project Area is on land managed for commercial forestry by S.D.S. Co., LLC and Broughton Lumber Company. All of the parcels on which the Project is located are managed for a continual
cycle of growth, harvest, and replanting. As a longstanding commercial forestry site, no old-growth forests exist in areas where the Project is proposed. Many of the remaining stands of trees on the sections of land that would have turbines on them are near maturity and S.D.S. Co., LLC and Broughton Lumber Company have recently implemented timber harvest plans on portions of these sections. Harvests have occurred in the Project Area over time, pursuant to long-established harvesting schedules (Figure 2-3).

Harvests have typically occurred approximately every 50 years; however, the harvest periods vary depending on the market and the demand for the type of timber. As a result, some harvests have occurred as frequently as every 40 years, and some have been up to every 65 to 70 years. Additional harvests are planned, subject to requirements of a Forest Practice Application.

In areas surrounding the proposed wind turbines that have not been recently harvested, or that are not planned to be harvested before Project construction, trees would be harvested and the land would be replanted with seedlings. This clearing would allow for safe construction of the proposed Project, and would reduce the potential for tree growth to interfere with the wind resource on the site during the commercial life of the Project (that is, during the 30-year commercial life of the Project, trees that are planted at the time of construction in the cleared area would regrow at a rate that would not interfere with wind energy production).

Typically, the cleared area for the wind turbines would extend approximately 50 feet in all directions from each turbine. From a distance of approximately 50 feet to 150 feet from the base of the turbines, tree heights would be limited to a height of approximately 15 feet above the elevation of the base of the turbine. Extending from approximately 150 feet to 500 feet from the base of the turbines, there would be a restriction of approximately 50 feet in height above turbine foundation level for trees located within an area formed by a 90-degree angle centered on the prevailing wind direction and on the downwind side of the prevailing wind direction. Final locations and dimensions would be determined during the final design, micrositing and construction process (Figure 2-4).

In addition to clearing around the turbines, there would be an approximately 100-horizontal-foot limitation placed on trees along any overhead electrical cable corridors, or such standards as are determined by the Project engineers in consultation with BPA or others, as applicable. The permanently disturbed, cleared area described above would be considered a “forest conversion” under the Washington Forest Practices Act, because it is being implemented for the purpose of the Project. However, to the extent feasible for the Project, cleared areas would be reforested in accordance with typical commercial forestry management practices.

The areas where tree clearing is required would be clear-cut using crawler tractors, rubber-tired skidders, and mobile feller-bunchers, as has been done on other stands on the property. Logs would be transported by truck to SDS facilities in Bingen, Washington. Except for areas to be maintained and permanently cleared for the construction of permanent improvements and ongoing operations and maintenance access needs (which would be replanted with appropriate native grasses and low-growing shrubs), cleared areas would be replanted with trees within one year after completion of construction (tree planting is done in the spring of each year).

Whistling Ridge Energy Project
Skamania County, Washington
2.1.7 PROJECT DECOMMISSIONING

For financial evaluation and contractual purposes, the Whistling Ridge Energy Project is expected to have a useful life of at least 30 years. While some Project elements may have a typical lifespan of only about 30 years, the trend in the wind energy industry has been to “repower” older wind energy projects by upgrading equipment with more efficient turbines. It therefore is likely that the Project would be upgraded with more efficient equipment and have a useful life longer than 30 years.

However, if the Project were terminated, the necessary authorization from the appropriate regulatory agencies would be obtained to decommission the facilities. All aboveground facilities would be removed from the site, and unsalvageable material would be disposed of at authorized sites. To avoid unnecessary future ground disturbance and related environmental impacts, the turbine foundations would likely be removed to a depth of 3 to 4 feet below ground surface (bgs), and underground electrical cables would likely be abandoned in place. The soil surface would be restored as close as reasonably possible to its original condition. Reclamation procedures would be based on site-specific requirements and forest management techniques commonly employed at the time the area would be reclaimed, and would include re-grading, adding topsoil, and replanting all disturbed areas. Decommissioned roads would be reclaimed or left in place based on landowner preference, and right of way would be surrendered to the landowner.

In compliance with WAC 463-72, Site Restoration and Preservation, Whistling Ridge Energy LLC would provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project were suspended or terminated during construction or before it has completed its useful operating life. The plan would include or parallel a decommissioning plan for the Project that assesses potential impacts from restoration activities and would be subject to appropriate environmental review.

2.2 NO ACTION ALTERNATIVE

Under the No Action Alternative, the state of Washington would deny the Applicant’s application for a Site Certificate for the proposed Whistling Ridge Energy Project, and/or BPA would not grant interconnection of the Project to the FCRTS. As a result, the proposed Whistling Ridge Energy Project would not be constructed or operated under this alternative. This alternative would not help utilities seeking renewable energy resources in states with RPSs, such as the state of Washington, Oregon, and California, in achieving the renewable energy goals mandated by each the state’s RPS. Furthermore, this alternative would not help to meet the region’s need for additional power in coming years. If the proposed Project is not constructed, it is likely that this need would be addressed by some combination of energy efficiency and conservation measures, existing power generation sources, and/or the development of other new renewable and non-renewable generation sources.

In addition, it is reasonably expected that under the No Action Alternative, the proposed Project site would continue to be used for logging and other timber harvest activities. This site has been in commercial forestry use for the last century, during which the site has been logged over a
series of approximately 50-year logging rotations. If the proposed Project is not approved and built, the Applicant and others would continue to use the site for commercial forestry production. Ongoing timber management activities within the Project Area under this alternative would include regular tree clearing, harvesting, replanting, and development of additional access roads as necessary.

### 2.3 ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

The Applicant has proposed a wind generation facility at the site discussed in Chapter 1 as a specific site. The lead agencies, Washington EFSEC and BPA, must respond to the Applicant’s requests for authorizations and approvals for the proposed wind project at this site. While this EIS focuses on the alternatives of either granting or not granting the Applicant’s requests, various other alternatives have been considered for the proposed Project. These alternatives include alternative locations for the proposed Project, different Project sizes, alternative wind generation technologies, and different Project configurations. For potential alternatives, the Applicant has identified a number of criteria that must be met in order for the Applicant to have a technically and economically feasible project:

- The Project must be located in an area with a steady supply of robust wind power, and on a site on which construction could reasonably occur (no significant geotechnical constraints);

- To reduce startup costs, the Project must be located on land the Applicant owns and controls, and land that can serve a dual purpose of commercial forestry and power production;

- To enable the power to reach urban markets and eliminate the cost and time required to construct new transmission lines, the Project must be located in proximity to existing high-voltage transmission lines;

- The costs of construction must be outweighed by the potential return on investment, requiring a minimum number of potential megawatts to be achieved by the Project; and

- The Project output must be at a competitive price and of adequate supply to be attractive to utilities looking to fulfill their Renewable and Alternative Energy Portfolio Standards.

The following sections describe alternatives that were considered but eliminated from detailed study in this EIS because of technical or economic feasibility issues, not meeting the identified purpose and need for proposed action, or clearly greater environmental impacts.
2.3.1 ALTERNATIVE PROJECT LOCATIONS

The Applicant owns approximately 70,000 acres of timberland in Washington and Oregon and manages its forestlands with the objective of producing as much high quality wood as possible without compromising the future economic and environmental benefits of their forests. In reviewing its lands for a potential location of a wind project, the Applicant sought:

- Areas of Applicant-owned property found to have a steady source of robust wind;
- Applicant-owned land that contained high ridges on which to place wind turbines with little impact to the continued underlying use of the land for commercial forestry; and
- Land in proximity to existing high voltage transmission lines.

To further clarify turbine string site selection, six suitability requirements were considered. They are as follows: lands owned by the Applicant or Broughton Lumber; within three miles of BPA transmission lines; outside of CRGNSA boundary; suitable terrain; road access; and contains at least 1,000 “suitable” lands. Furthermore, “suitability” is described as follows:

- **Low suitability properties**: These are parcels that are within 3 miles of transmission lines, are outside the NSA boundary, have a terrain difference of between 200 and 500 feet, and have road access. These parcels are designated in yellow on the “Tract Suitability Analysis” map (see Figure G-1 in Appendix G).

- **Potentially suitable properties**: These are parcels that are within 3 miles of transmission lines, are outside the NSA boundary, have a terrain difference of between 500 and 1,000 feet, and have road access. It should be noted that these parcels could be ruled out as being unsuitable based on other factors not assessed in this analysis, such as slope direction or parcel size. These parcels are designated in brown on the “Tract Suitability Analysis” map (see Figure G-1 in Appendix G).

- **Suitable properties**: These are parcels that are within 3 miles of transmission lines, are outside the NSA boundary, have a terrain difference of between 500 and 1,000 feet, and have what appear to be better road access than properties identified as “potentially suitable”. These parcels are designated in dark pink on the “Tract Suitability Analysis” map (see Figure G-1 in Appendix G).

- **Highly suitable properties**: These are parcels that are within 3 miles of transmission lines, are outside the NSA boundary, have terrain differences between 1000 and 2000 feet above surrounding terrain and contain the highest hills/ridgelines within the study area, and have good road access. These are the best possible locations within the study area for wind facility development. Of the analyzed parcels, only 1 parcel fell into this category. These parcels are designated in blue on the “Tract Suitability Analysis” map (see Figure G-1 in Appendix G).

- The proposed Whistling Ridge Energy Project site was selected for its location within the “highly suitable properties”. This site was then forwarded for further environmental analysis including wildlife surveys.
No other sites were identified that are under the ownership of the Applicant or as close to existing transmission infrastructure facilities.

### 2.3.2 LARGER OR SMALLER GENERATION FACILITY SIZE

During the Project planning process, the Applicant considered the feasibility of constructing and operating a larger generation facility, both in terms of more wind turbines and a larger area, involving the proposed Project Area. Regarding more turbines, the site does contain a series of ridge lines that are conducive to locating wind turbines but at the same time are limiting as to where those turbines could be placed. In general, placement of turbines in areas substantially below the ridge lines would not effectively make use of the wind resource within the Project Area, thereby compromising the economic feasibility of the proposed Project. Accordingly, the constrained topography has necessitated a restricted power plant design.

Regarding a larger area for the proposed Project, the Project Area is located between the National Scenic Area on the south and land owned by Washington DNR on the north. While the Applicant did not consider locating turbines within the National Scenic Area due to its sensitivities, consideration was given to locating turbines on the DNR lands directly north of the site. These lands have similar topographical characteristics as the proposed Project site, and also have been logged through commercial forestry activities. However, use of these lands for Project turbines was rejected from further consideration due to comments from the public and DNR’s own reluctance to consider leasing the site to the Applicant.

Lands east and west of the proposed Project Area also were considered but were rejected from further evaluation because these lands were at a lower elevation and did not include the north-trending ridge lines suitable for wind turbine placement that exist on the proposed site.

The Applicant also considered the feasibility of a smaller generation facility in the proposed Project Area, either by removing turbines or utilizing a smaller Project Area. However, the Project is proposed as an “integrated whole,” as a single power plant, not pieces of a whole, where some turbines may be eliminated. The Project proposes a defined output, based on site and design characteristics and market demand and Applicant objectives. These objectives include providing a minimum level of generation to be attractive to utilities seeking to fulfill their RPS requirements, as well as providing a return on investment to the Applicant. In order to provide this return, the Applicant has determined that the Project must be capable of producing a minimum of 70 MW. The number of wind turbines in the Project Area has already been minimized to the extent practicable in light of the Applicant’s objectives. Accordingly, if any turbines are removed from the Project design, other locations must be found to replace those turbines to maintain the minimum necessary capacity. The constrained site location and topography limits the ability to relocate turbines within the Project Area.

In sum, the Project size was selected to optimize Project energy output and economic feasibility. A smaller wind turbine facility would be unlikely to offset Project development costs. A larger project would require additional infrastructure capacity and transmission capacity.
2.3.3 ALTERNATIVE WIND GENERATION TECHNOLOGIES

Consideration was given to alternative technologies for the generation of power from a wind resource. Several types of wind energy conversion technologies have been developed over the past three decades and include (1) vertical axis Darrieus wind turbines, (2) two-bladed downwind wind turbines, (3) smaller three-bladed upwind wind turbines (500 to 750 kW), and (4) larger 3-bladed upwind wind turbines (1 to 3 MW). The three-bladed, upwind, horizontal axis is currently the preferred technology, based on proven reliability and commercial viability.

2.3.4 ALTERNATIVE PROJECT CONFIGURATIONS

As discussed above, the proposed Project Area contains a series of ridge lines that are conducive to locating wind turbines but at the same time are limiting as to where those turbines could be placed. This means that there are limited options for locating wind turbines within the site. Alternative turbine configurations were considered, but were eliminated from further study because they either did not appropriately utilize the wind resource present at the site or compromised the economic feasibility of the proposed Project.

2.3.5 ALTERNATIVE INTERCONNECTIONS

Alternatives for interconnecting with BPA’s existing high voltage transmission lines that currently cross the proposed Project Area were considered. The currently proposed location of the substation was chosen because it is a relatively clear and low-elevation area that is adjacent to the proposed site of the Operations and Maintenance facility.

Initially, an option of providing interconnection to the FCRTS at a point along the North Bonneville-Midway 230-kV transmission line within the Project Area and directly east of the currently proposed interconnection point was identified. This alternative interconnection point was located between structures 22/6 and 23/1 on the North Bonneville-Midway 230-kV transmission line. However, this option would have required the development of interconnection facilities within the National Scenic Area because structure 22/6 is on the border of, and structure 23/1 within, the Scenic Area. Given the high sensitivity of the Scenic Area, construction of an interconnection alternative within its boundaries was eliminated from further study.

An alternative interconnection also was considered off of the Project Area, approximately 1.5 miles west of the currently proposed interconnection point. BPA’s transmission engineers identified a potential alternative interconnection site between structures 21/4 and 22/1 on the North Bonneville-Midway 230-kV transmission line. This site was located in a relatively flat, lower-elevation area that may have easier access in the winter than the currently proposed interconnection site. However, this alternative would have required the Applicant to construct and operate a new 1.5 mile section of 230-kV transmission line from the Project Area to this interconnection point. Development of such a new line would have required the clearing of an approximately 125-foot-wide right-of-way corridor for the line, as well as the clearing and construction of additional new transmission line access roads. This corridor would be located in steep terrain, and would require timber harvesting, new access roads, and vegetation control in areas where slopes approach 100 percent in places. In addition to potential additional impacts to plants, wildlife, cultural resources, aquatic areas, and wetlands that could be avoided by siting the Project substation within the Project Area, this alternative likely would have greater visual...
and geological impacts due to the new transmission line corridor’s location on steep, more visible slopes.

The Applicant also has stated that the additional costs of constructing the new line associated with this alternative line likely would make the Project no longer economically viable. In addition to the substantial additional costs of constructing this additional line, timber harvesting operations on the steep terrain that exists in the potential narrow corridor for the new line under this alternative would be impossible to conduct economically adjacent to the existing BPA system unless a much larger area was harvested at the same time. Because of the much greater potential for environmental effects as compared to merely developing the currently proposed interconnection within the already planned Project Area, as well as the significant additional cost implications, this alternative was considered but eliminated from detailed study in this EIS.

Finally, an interconnection with the other existing BPA transmission line that crosses the Project Area also was considered. However, this alternative was rejected from further study because the other existing BPA line is a 115-kV transmission line that does not have sufficient capacity to transmit the energy from the Whistling Ridge Energy Project.

2.3.6 ALTERNATIVE ACCESS ROADS

During Project planning, different alternatives for accessing the proposed Project Area were assessed. There are three potential ways to access the Project Area. All are via County roads from SR 14 to Cook-Underwood Road. In addition to the proposed access route that is included as part of the Proposed Action, from Cook-Underwood Road, the Project Area could be accessed by:

- **Route 1:** Ausplund Road to a private logging road vacated by Skamania County in 1987, which crosses private property (not owned by the Applicant) that is currently used for residential, agricultural orchards, and commercial timber production and harvest.

- **Route 2:** Kollock-Knapp Road to Scoggins Road to a private logging road called the CG2930 road on County Assessor’s maps, which crosses property owned by the Applicant that is currently used for commercial timber production and harvest.

The private logging road in Route 1 was made a County right of way in 1923. It was vacated for public use in 1987 by resolution of the Skamania Board of County Commissioners; however, the rights to use the road by abutting property owners remain. Additionally, road improvements to this route would be required for access to construct the wind energy facility and for ongoing operations and maintenance traffic. Impacts to a non-project landowner from these activities would occur if Route 1 were used. Therefore, Route 1 has been eliminated as a construction roadway access alternative.

Route 2 would require minor roadway improvements that would not directly impact any non-project landowners. However, these roadway improvements would require construction within the National Scenic Area. Therefore, Route 2 has been eliminated as a construction roadway access alternative.
2.4 BENEFITS AND DISADVANTAGES OF DELAYING PROJECT IMPLEMENTATION

The Washington SEPA Rules require that an EIS discuss the benefits and disadvantages of reserving for some future time the implementation of a proposal, as compared with possible approval at this time. See WAC 197-11-440(5)(c)(vii). The benefits of deferring action on the proposal would include:

- Delaying or deferring construction-related traffic, noise and dust impacts during the Project construction period.
- Delaying or deferring potential impacts related to visual resources from Project operation. These impacts would occur primarily due to the visibility of proposed Project wind turbines from various vantage points in the Project vicinity, including some viewpoints within the Columbia River Gorge National Scenic Area.
- Delaying or deferring potential increased noise levels from wind turbine operation at nearby noise-sensitive receivers.
- Delaying or deferring permanent removal of approximately 60.7 acres of vegetation and potential wildlife habitat for Project facilities.
- Delaying or deferring potential mortality to birds and bats due to turbine collision and displacement.
- Delaying or deferring use and consumption of fuels, water, and other natural resources that would be required for Project construction and operation.
- Delaying or deferring construction impacts of traffic, noise and dust
- Delaying or deferring potential operational impacts on noise, visual resources, and wildlife

The disadvantages of deferring action on the proposed Project would include the following:

- Delaying approval of the Whistling Ridge Energy Project would not help utilities seeking renewable energy resources in states with RPSs, such as Washington, Oregon, and California, in achieving the short-term renewable energy goals mandated by each state’s RPS; however, depending on the length of the approval delay, the Project could be available for meeting the longer term goals of these RPSs. The Whistling Ridge Energy Project would not help the state of Washington in achieving the renewable energy goals mandated by the state’s RPS.

- Deferring the Whistling Ridge Energy Project would not help to meet the region’s need for additional power in near-term coming years, but approval at some future time could make the Project available for longer-term power needs. Regardless, if the proposed Project is not constructed, it is likely that these needs would be addressed by some combination of energy efficiency and conservation measures, existing power generation sources, and/or the development of other new renewable and non-renewable generation sources.
• If the proposed Project is deferred, the proposed Project Area would continue to be used for logging and other timber harvest activities so there would be continued impacts from access, timber cutting, and replanting over time. This site has been in commercial forestry use for the last century, during which the site has been logged over a series of approximately 50-year logging rotations. If the proposed Project is not approved and built, or if approval is deferred, the Applicant and others would continue to use the site for commercial forestry production. Ongoing timber management activities at the Project Area would include regular tree clearing, harvesting, replanting, and development of additional access roads as necessary.

• During the period of any delay or deferral, the Applicant would be denied the ability to create new business and job opportunities through diversifying and maximizing the use of its existing holdings.

• During the period of any delay or deferral, up to a peak of 265 new construction jobs in Skamania County would not be created.

• If Project approval is delayed, eight to nine new operation jobs in Skamania County would not be created starting in about 2012 when the Applicant hopes to begin commercial power production; however, these jobs could be created in the future if the Project is deferred but approved at some later time.

• A new revenue source to Skamania County and the state of Washington from the payment of sales and business taxes would be deferred or eliminated.

2.5 COMPARISON OF ALTERNATIVES

Under the Proposed Action, the state of Washington would approve the Applicant’s application for a Site Certificate for the proposed Whistling Ridge Energy Project, and BPA would grant interconnection of the proposed Project to the FCRTS. Under the No Action Alternative, the state of Washington would deny the Applicant’s application for a Site Certificate for the proposed Project, and/or BPA would not grant interconnection of the Whistling Ridge Energy Project to the FCRTS.

Table 2-5 compares BPA’s Proposed Action (granting the proposed interconnection) and the No Action Alternative (not granting the proposed interconnection) to the BPA purposes identified in Chapter 1 of this EIS. Table 1-1 in Chapter 1 of this EIS summarizes the potential overall environmental impacts and mitigation for the proposed Project and interconnection, as well as alternatives including the No Action Alternative. Detailed analysis of potential impacts is contained in Chapter 3 of this EIS.

3.0 AFFECTED ENVIRONMENT, IMPACTS AND MITIGATION

This chapter describes the existing environmental resources in the vicinity of the proposed Project and the potential impacts that the Proposed Action and the No Action Alternative would have on those resources. The potential impacts described were determined through research and field observation by environmental specialists and information provided by agency and public comments. More specific information on methodology for each resource is provided as appropriate. Each resource lists the mitigation measures that would lessen impacts, and the impacts that would be unavoidable.

Toward the end of the chapter, cumulative impacts are described, followed by discussions of intentional destructive acts, relationship between short-term uses of the environment and long-term productivity, and irreversible or irretrievable commitments of resources.

3.1 EARTH

This section discusses the existing setting and potential Project impacts related to geology, soils and topography. This analysis includes potential impacts of the Proposed Action on resources, and potential impacts of geologic hazards such as earthquakes or landslides on the Project. This section includes information submitted as part of the Application for Site Certification (Appendix A) and the background data to that document (Appendix B Geotechnical Report).

3.1.1 AFFECTED ENVIRONMENT

3.1.1.1 Topography

The 1,152-acre proposed Project Area is situated on a series of north-trending ridges that range in elevation from approximately 2,100 to 2,300 feet above mean sea level (msl). The land west of the proposed Project Area drops sharply to a narrow river terrace and then to an elevation of less than 800 feet above msl in the Little White Salmon River valley. The topography northeast of the site drops gradually toward the White Salmon River or climbs gently up the northeast flank of Underwood Mountain at 2,728 feet above msl. To the south, the topography drops to a terrace of largely agricultural use and then toward the Columbia River. Figure 3.1-1 shows the site topography.

3.1.1.2 Regional Geology

The White Salmon, Washington, area is located within the Cascade Range and the Columbia Intermontane Physiographic Province. The Project Area is located just within the western boundary of the Columbia Plateau, which is located at the western edge of the Columbia Intermontane Physiographic Province. This lowland province is surrounded on all sides by mountain ranges and highlands, and covers a vast area of eastern Washington and parts of northeastern Oregon and western Idaho.

Whistling Ridge Energy Project
Skamania County, Washington
The Columbia Plateau is underlain by a series of layered basalt flows extruded from vents (located mainly in southeastern Washington and northeastern Oregon) during the Miocene epoch (between 5.3 and 23.8 million years before present [BP]). Individual basalt flows ranged in thickness from a few millimeters to as much as 300 feet. Where significant time elapsed between successive flows, interflow zones developed. The interflow zones are characterized by the presence of highly weathered basalt and paleosols. These interflow zones are generally significantly weaker than the surrounding basalt and sometimes form basal failure surfaces for large landslide complexes.

Above the basalts are a variety of younger volcanic rocks and sedimentary materials that range from Pliocene (1.8 to 5.3 million years BP) to Holocene (less than 10,000 years BP). Sedimentary rocks are generally thought to underlie the basalts.

Individual geologic units in the general area are primarily Underwood Mountain Basalt, as described in Section 3.1 of the Application for Site Certification (Appendix A). Near-surface rock consists of yellow-gray volcanoclastic rocks, medium to dark gray, fine-grained to medium-grained basalt and andesite, which is fractured into angular gravels, cobbles, and boulders.

Regional geologic maps indicate the presence of Quaternary-age mass wasting landslide deposits located north of Underwood Mountain (Figure 3.1-2). These deposits are mapped as a large landslide, estimated to be approximately 1/3 square mile in area and almost a mile long. However, based on field work conducted in 2007, there is no obvious evidence to suggest the presence of a landslide as mapped on the 1:100,000 scale geologic map. If landslide deposits are present, they have been exposed long enough that most or all of the geomorphic evidence has been removed by erosion.

### 3.1.1.3 Local Geology and Soils

**Geology**

The proposed Project Area is located within the northern boundary of the Hood River Valley, which extends a few miles into southern Washington. In general, the geology of the area consists of basalt flows extruded from local vents, layered with conglomerate, tuff, tuff breccias, and other volcanoclastic deposits (Figure 3.1-2).

The bedrock underlying the proposed Project Area consists of Grande Ronde Basalt of the Columbia River Basalt Group and Quaternary basalt of Underwood Mountain—a shield volcano that lies approximately midway between the lower reaches of the Little White Salmon and White Salmon Rivers. Its southern slopes drain to the Columbia River.

In the Project Area, these basalt formations are typically overlain by silt and clay soil of varying thickness. Unconsolidated deposits are thin to absent with surface materials consisting primarily of a veneer of brown, silty topsoil that is likely derived from forest duff and wind-blown deposits. The thickness of this material varies across the site from a few inches to three feet. In several areas, bedrock and talus can be observed at the ground surface.
Figure 3.1-2
Site Geology

Soils

Soil Types. Figure 3.1-3 shows soils in the Project Area. The Natural Resources Conservation Service (NRCS) describes the soils in the Project vicinity as follows (USDA NRCS 2003):

- **McElroy Series.** The McElroy series consists of very deep soils (up to 5 feet) formed in colluvium and residuum from basalt with a mantle of volcanic ash that influences soils in the top 9 to 13 inches. The soils exist on the footslopes and backslopes of mountains on slopes from 5 to 90 percent at elevations from 400 to 2,600 feet in eastern Skamania County and western Klickitat County. McElroy Soils are well drained with medium to rapid runoff and moderate permeability. The series was established in 1981 following the introduction of volcanic ash from the eruption of Mt. St. Helens.

- **Timberhead Series.** The Timberhead series consists of very deep soils (up to 5 feet) formed in residuum and colluvium from basalt mixed with volcanic ash. The soils exist on mountain ridges between 5 and 30 percent at elevations from 2,000 to 3,600 feet in Skamania County and western Klickitat County. Timberhead Series soils are well drained with medium to rapid runoff and moderately high to high permeability.

- **Underwood Series.** The Underwood series consists of very deep soils (5 feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between 2 and 50 percent at elevations between 500 and 2,700 feet in southeast Skamania County and west Klickitat County. Underwood Series soils are well drained with slow to medium runoff and moderately high permeability.

- **Undusk Series.** The Undusk series consists of very deep soils (5 feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between 5 and 65 percent at elevations between 2,000 and 2,800 feet in southeast Skamania County and west Klickitat County. Undusk Series soils are well drained with slow to medium runoff and moderately high permeability.

Based on the current test pits and field observations, the site soil is best represented as Soil Site Class D (stiff soils). Rock with varying strength and weathering characteristics was encountered at depths ranging from 3 to 12 feet bgs.

Soil Erosion Potential. Erosion is the breakdown and transport of soils and bedrock by natural processes, including water, wind, and glaciation. The susceptibility of any material to erosion depends on chemical and physical characteristics; topography; the amount and intensity of precipitation and surface water; the intensity of wind; and the type and density of vegetative ground cover, if present.

Erosion potential was assessed for the Application for Site Certification, principally based on the erosion potential specified for surficial soils by the NRCS. These erosion factors indicate that the Underwood loam has a high potential for erosion by water and the McElroy, Timberhead, and Undusk units have a medium potential, with the remaining soil types having a low potential. Most soils found in the site vicinity are classified as having a low susceptibility to wind erosion.
Soil Classifications

Data Source: USDA NRCS, Skamania County Area, Washington, Soil Survey - Wa659.
3.1.1.4 Geologic Hazards

**Earthquakes**

Earthquakes are the result of sudden releases of built-up stress within the tectonic plates that make up the earth’s surface. Stress accumulates where movement between plates or on faults produces friction. No faults are mapped within the footprint of the proposed Project Area. However, faults are mapped approximately 1.5 miles to the southwest and northeast. (Pezzopane 1993 and Geomatrix 1995) Many of these faults are inferred, and shown as dotted lines buried by younger surficial deposits. While the activity of the area faults is unknown, a review of aerial photography showed no indication of recent movement along the trace of the inferred faults.

There have been no surface-rupture earthquakes on any fault within northwestern Oregon or southwestern Washington in historic times, and investigations of the regional faults have been limited.

According to the updated National Seismic Hazard Maps published by the US Geological Survey (USGS) in 2008 (Petersen et al. 2008 and USGS 2009), the peak ground acceleration estimated for the area of the Whistling Ridge site is 0.18g for a 475-year return period earthquake (i.e., ground motion with a 10 percent chance of being exceeded in 50 years) and 0.40g for a 2,475-year return period earthquake (i.e., ground motion with a 2 percent chance of being exceeded in 50 years).

Large earthquakes at more distant faults could cause prolonged ground movement in the Project Area. Information on historic large earthquakes can be found in the Application for Site Certification Section 3.1 (Appendix A).

**Landslides**

As part of the Application for Site Certification, a preliminary landslide hazard evaluation of the Project Area was conducted by a licensed geologist pursuant to Skamania County Code (SCC) Title 21A, Chapter 21A.06 - Landslide Hazard Areas (LHAs), which are shown on Figure 3.1-4. Skamania County recognizes three classes of LHAs.

- Class I (Severe) LHAs are considered to present a severe landslide hazard and are distinguished as areas of known mappable landslide deposits that have been designated by the local legislative body.

- Class II (High) LHAs are areas with slopes between 20 and 30 percent that are underlain by soils that consist largely of silt, clay or bedrock, and all areas with slopes greater than 30 percent.

- Class III (Moderate) LHAs are areas with slopes between 20 percent and 30 percent not included in Class II.

Figure 3.1-4
Landslide Hazard Areas

Job No. 33758687

Whistling Ridge Energy Project
Skamania County, Washington
The preliminary landslide hazard evaluation concluded that there do not appear to be any areas in the site that meet Skamania County’s criteria for a Class I LHA. Figure 3.1-4 shows Class II LHAs in green. The Class II LHAs at the site are predominantly associated with the steep slopes west of proposed Tower Lines A and B. There are also steep slopes to the east of the seven southernmost Tower Lines A towers, and on both sides of Tower Line C. The Class II areas are generally bordered by smaller areas of Class III.

**Volcanic Eruption**

The Cascade Mountains of the Pacific Northwest region contain sixteen major volcanoes, which extend from Mount Garibaldi in British Columbia to Lassen Peak in California (Harris 1988). Four of the volcanoes within Washington and Oregon have experienced activity within historic time: Mount Baker, Mount Rainier, Mount Hood, and Mount St. Helens. Mount Adams is the closest volcano to the Project Area, situated approximately 30 miles due north, but is not historically active. Mount St. Helens is the closest historically active volcano to the Project Area, situated approximately 42 miles to the northwest.

### 3.1.2 IMPACTS

#### 3.1.2.1 Proposed Action

**Construction**

Construction would involve approximately 108 acres of earth-disturbing activities (56 acres of permanent disturbance and 52 acres of temporary disturbance). Activities that would involve earth disturbance include tree harvesting in areas not already cleared; constructing roads and turbine crane pads; constructing foundations for turbine and meteorological towers; trenching for underground utilities; clearing and grading for the substation placement; and clearing and excavating for the foundation for the Operations and Maintenance facility at either of the two alternative locations. Approximately 50 percent of excavated soils are anticipated to be too large for re-use as backfill at foundations. Based on preliminary calculations and depending on the type of foundation design used, approximately 20 cubic yards of excavated soil would remain from each turbine foundation excavation.

Roadway improvements would be necessary to accommodate the heavy and long loads associated with the turbine towers. Improvements would be made to approximately 7.9 miles of existing roads, and 2.4 miles of new road would be built. Most of these improvements would be made in the Project Area, with the exception of off-site improvements to West Pit Road. For areas with steep slopes, it may be necessary to flatten and rebuild the slopes to allow access for the long loads required. Some steep sections of existing or new roads may be graded to create shallower grades, and some tight-radius turns may require localized rerouting of existing roads. West Pit Road would require permanent widening to accommodate long loads. Widening could include removal of trees and other vegetation, along with engineered cut and fill sections (cut and fill volumes would be calculated during final design). The road would not require paving, but would require an all-weather driving surface.

The primary impacts during construction would be potential for erosion, landslides, soil compaction and changes to topography.
Soils

Because some surface soils in the Project Area are moderately susceptible to erosion, there is some potential for adverse impacts on the site soil in areas of steep topography during grading and foundation construction, as shown on Figure 2.15-1, Landslide Hazard Classifications, in Section 2.15 of the Application for Site Certification (Appendix A).

Topography

Changes to the topography would include grading turbine foundations and access roads. The changes to topography would be minor to moderate depending on location.

Erosion

The potential for erosion or aggradation would be greatest during the construction process. The NRCS classifies surficial soils at the site as generally having medium erosion potential. During the dry season, soils that are disturbed and stripped of vegetative cover may be susceptible to wind erosion. The potential for erosion by wind and water would be minimized through the use of best management practices (BMPs).

Operation

Once the Project is constructed, the primary risks would be associated with earthquakes, volcanic activity, and landslides.

Earthquakes

Liquefaction. Liquefaction is a phenomenon whereby soils undergo significant loss of strength and stiffness when they are subjected to vibration or large cyclic ground motions produced by earthquakes. Saturated soils without cohesive fines (i.e., gravels, sands, and silts) are most susceptible to liquefaction. Other factors affecting the potential for liquefaction in soils are density, amplitude of loading, confining pressure, past stress history, age of soil deposit, the size, shape and gradation of particles, and the soil fabric structure. In earthquakes, liquefaction-induced ground settlement and lateral spreading have been the primary cause for extensive damage to aboveground structures, foundations, and pipelines.

Field investigation concluded that the potential for liquefaction is very low at this site. Test pits excavated at the Project Area encountered shallow bedrock covered with a combination of cohesive and cohesionless soil. No groundwater was observed in any of the test pits.

Structure failure could occur with enough ground shaking even without liquefaction. However, this hazard would be mitigated by adhering to seismic building codes.

Settlement. Field investigation concluded that settlement and lateral spread induced by a seismic event would be minimal, due to the low liquefaction potential.

Surface Rupture. Surface rupture occurs when a fault breaks to the land surface during an earthquake. Surface rupture is usually associated with moderate to large earthquakes (Mw 6.5 or greater) or rarely during smaller, very shallow events. There are no mapped faults crossing the site. Therefore, the potential for primary surface rupture in the proposed Project Area is small.
Volcanic Activity

Effects of volcanic activity are unavoidable and may include lava flows, mudflows, pyroclastic flows, and ash-fall. Volcanic flows are typically limited to the flanks of the volcano and major drainage channels extending from the volcano, which for all known volcanoes in the area are located outside the Project Area. The largest potential impact to the site from volcanic activity would be ash carried aloft that subsequently falls to the land surface. Based on prevailing wind patterns, the USGS (Wolfe and Pierson 1995) estimates that there is between a 0.02 and 0.1 percent annual probability that there would be 4 inches (10 cm) or more of ash deposited at the site from eruptions throughout the Cascade Range (Figure 2.15-2 in the Application for Site Certification). The adverse effects on wind turbines from ash fall would be mitigated through appropriate design.

Landslides

The landslide evaluation conducted for the Application for Site Certification concluded that the Project could be constructed and operated without danger to human life or the surrounding environment due to landslide hazards.

Although none of the proposed turbines are located within Class II LHAs, several of the towers along the western side of the Project Area (Tower Lines A and B) are located along ridgelines with descending slopes that are locally greater than 35 degrees (70 percent). Based on studies conducted for the Application for Site Certification, it appears that the primary concern for towers located adjacent to the Class II LHAs is the potential for headward erosion of the steep drainages by debris or earth flow processes. Erosion rates of these drainages are unknown, but no obvious recent mass wasting features were observed in the aerial photos or during the site reconnaissance. Further subsurface investigation in support of final tower foundation design would help determine if there are weak rock or soil layers that could contribute to more deep-seated failure of the ridges and provide information on the quality of the rock underlying the ridgelines.

Class III LHAs were delineated adjacent to proposed wind turbines along the southern Tower Line A and along Tower Line C. Class III LHAs are not anticipated to have any impact on the proposed facilities due to the robust nature of the proposed foundation designs.

Project Decommissioning

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. A detailed site restoration plan is required within ninety days from notification of Project termination. The initial site restoration plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is suspended or terminated during construction or before it has completed its useful operating life. The initial site restoration plan would include or parallel a decommissioning plan for the Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential changes to soils, topography, or erosion. If impacts to earth are anticipated to
occur as a result of site restoration and Project decommissioning, mitigation measures would be proposed as part of the plan.

### 3.1.2.2 No Action Alternative

Under the No Action Alternative, no structures would be built and there would be no road construction or improvement. Potential impacts to the site from geologic hazards would continue as under present conditions. Some potential for erosion could continue from ongoing logging activity, as mitigated by Washington State requirements and BMPs.

### 3.1.3 MITIGATION MEASURES

The following mitigation measures are identified to avoid, minimize, and compensate for potential impacts of the proposed Project related to geology, soils, topography, and geologic hazards.

- Prior to Project construction, confirm subsurface soil and rock types and strength properties through a detailed geotechnical investigation of the specific locations of all wind Project elements, including wind turbines, access roads, underground trenching corridors, electrical grounding systems, and the substation and Operations and Maintenance facility locations.

- If detailed geotechnical investigations indicate potential for slope instability at Project facilities, ensure that design of these facilities included proper engineering to account for this risk or relocate the facilities on-site to avoid this risk.

- Prepare and implement a Stormwater Pollution Prevention Plan (SWPPP), Erosion and Sedimentation Control Plan, and Environmental Protection Control Plan to lessen soil erosion and improve water quality of stormwater run-off through stabilization practices, structural practices, and stormwater management. These Plans would be developed and approved by EFSEC prior to construction or modification of any roads or facilities. **EFSEC may require the Applicant to obtain coverage under Ecology's Construction Stormwater General Permit because the Project would disturb more than 1 acre of land.**

- Build all structures on the site in accordance with the seismic design provisions of the 2006 version of the International Building Code, and the American Society of Civil Engineers 07-05 standard. Foundations and buildings would be designed for Seismic Zone 2, and the values listed in Table 3.1-1 would be used for seismic design of the Project in accordance with Section 1613.5.3 of the 2006 International Building Code. The occupancy category of the proposed structure is assumed III as per Section 1613.5.6 of the 2006 International Building Code.

ASCE – American Society of Civil Engineers
IBC – International Building Code
<sup>a</sup> Assumes Seismic Use Group III

- Conduct a visual inspection of Project facilities following any abnormal seismic activity. These inspections would look for signs of incipient mass movement in areas identified as potentially susceptible to such failures.

- Implement all stormwater pollution prevention activities prior to any clearing and site preparation. Measures would include installation of a stabilized construction entrance, wheel wash, silt fences, hay bales, temporary and/or permanent water conveyance systems, and installation of temporary and/or permanent retention ponds. Dust would be controlled as needed by spraying water on dry, exposed soil.

- Limit clearing, excavation and grading to those areas of the Project Area absolutely necessary for construction of the Project. Areas outside the construction limits would be marked in the field and equipment would not be allowed to enter these areas or to disturb existing vegetation.

- Inspect any installed run-off and erosion control structures at a frequency sufficient to provide adequate environmental protection. Such inspections would increase in frequency during rainfall periods.

- Store additional erosion control supplies, including sandbags and channel-lining materials, on site for emergency use.

- Divert surface runoff around and away from cut and fill slopes using pipes and/or protected channels. If the runoff is from disturbed areas, it would be directed to a sediment trap prior to discharge.

- Construct all Project roads to be gravel surfaced with a low profile. Road construction would be performed in multiple passes starting with the rough grading and leveling of the roadway areas, if necessary. Once rough grade is achieved, a fabric layer would be installed, base rock would be trucked in, spread and compacted to create a road base. A capping rock would then be spread over the road base and roll-compact to finished grade.
• Placement of all spoils piles would be regulated by the conditions of the stormwater permits.

• Spread soil and rock that is excavated through grading across the site to the natural grade and reseed with native grasses or seeds to control erosion by water and wind.

• Crush larger cobbles into smaller rock for use as backfill or road material or dispose of materials offsite. Those materials that cannot be reused on site would be disposed of in accordance with Skamania County and Ecology regulations for clean fill materials.

3.1.4 UNAVOIDABLE ADVERSE IMPACTS

The primary unavoidable impacts are the potential for landslide and erosion. Both can be mitigated through appropriate design and the application of mitigation measures, but some erosion would nonetheless occur.

3.1.5 REFERENCES

3.2 AIR QUALITY

This section describes the existing air quality conditions in the Project Area, the potential for impacts to air quality from the proposed Project, and mitigation measures designed to avoid or minimize those impacts.
3.2.1 AFFECTED ENVIRONMENT

Regulatory Overview

The Clean Air Act (CAA) is the primary federal statute governing air quality. The CAA establishes National Ambient Air Quality Standards for six “criteria pollutants,” and local agencies may establish Ambient Air Quality Standards themselves, provided that these are at least as strict as federal standards. Local air quality is measured against these national and state standards, and areas that do not meet the standards are designated as “non-attainment” areas. Skamania County does not have any non-attainment areas for air quality.

New stationary sources of air emissions in nonattainment areas must undergo more rigorous permitting than equivalently sized sources in attainment areas, in an effort to bring the nonattainment area back into compliance with the air quality standards. The state of Washington has established rules through Ecology for permitting new sources in both attainment and nonattainment areas of the state, and additional requirements may be imposed by local air authorities. EFSEC issues authorizations for air emissions for sources under its jurisdiction. In general, if potential emissions from stationary sources exceed certain thresholds, approval from the appropriate permitting authority is required before beginning construction.

Under the CAA, new industrial sources of air pollution must receive an air quality permit prior to operation. The two most common permits associated with industrial activity emitting regulated air pollutants are Notice of Construction (NOC)/New Source Review approvals and Prevention of Significant Deterioration (PSD) permits. WAC Chapters 463-39 and 173-400 establish the requirements for review and issuance of NOC approvals for new sources of air emissions under EFSEC jurisdiction. PSD regulations apply to proposed new or modified “major” sources located in an attainment area that have the potential to emit criteria pollutants in excess of predetermined de minimus values (40 Code of Federal Regulations [CFR] Part 51). For new generation facilities, these values are 100 tons per year of criteria pollutants for 28 specific source categories, or 250 tons per year for sources not included in the 28 categories.

The Project is not required to go through these permitting processes. A NOC is not required for the proposed Project because there would be no permanent sources of regulated air emissions, and no backup generation or spinning reserves would be required as part of the proposed Project. A PSD permit would not be required; the generation of electricity with wind turbines does not produce air emissions because no fuel is being burned to produce energy.

Although construction emissions are not included in permitting of stationary sources, mobile sources (such as construction equipment and maintenance pickups) are regulated separately under the federal CAA. In addition, Washington State also regulates emissions generated by various construction activities. According to WAC 173-400-300, fugitive air emissions are emissions that “do not and which could not reasonably pass through a stack, chimney, vent or other functionally equivalent opening.” These emissions include fugitive dust from unpaved roads, construction sites, and tilled land. Fugitive emissions are considered in determining the level of air permitting required only for a certain subset of sources, not including wind power.

projects. However, pursuant to WAC 173-400-040(8)(a), “The owner or operator of a source of fugitive dust shall take reasonable precautions to prevent fugitive dust from becoming airborne and shall maintain and operate the source to minimize emissions.”

Other Washington state regulations that apply to nuisance emissions, including fugitive dust, and various equipment used during construction include the following:

- **WAC 173-400-040(2) Fallout** states that no person shall cause or allow the emission of particulate matter from any source to be deposited beyond the property under direct control of the owner or operator of the source in sufficient quantity to interfere unreasonably with the use and enjoyment of the property upon which the material is deposited.

- **WAC 173-400-040(3–3a) Fugitive emissions** states that the owner or operator of any emissions unit engaging in materials handling, construction, demolition, or other operation which is a source of fugitive emissions, if located in an attainment area and not impacting any non-attainment area, shall take reasonable precautions to prevent the release of air contaminants from the operation.

- **WAC 173-400-040(4) Odors** states that any person who shall cause or allow the generation of any odor from any source that may unreasonably interfere with any other property owner’s use and enjoyment of his property must use recognized good practice and procedures to reduce these odors to a reasonable minimum.

- **WAC 173-400-040(8a) Fugitive dust** states that the owner or operator of a source of fugitive dust shall take reasonable precautions to prevent fugitive dust from becoming airborne and shall maintain and operate the source to minimize emissions.

- **WAC 173-400-035 Portable and Temporary Sources** states that for portable sources that locate temporarily at particular sites, such as rock crushers and batch plants, the owner(s) or operator(s) shall be allowed to operate at the temporary location providing that the owner(s) or operator(s) notifies Ecology or the local air quality authority of the intent to operate at the new location at least 30 days prior to starting the operation, and supplies sufficient information to enable Ecology or the local air quality authority to determine that the operation would comply with the emissions standards for a new source, and would not cause a violation of applicable Ambient Air Quality Standards and, if in a non-attainment area, would not interfere with scheduled attainment of ambient standards. The permission to operate shall be for a limited period of time (one year or less) and Ecology or the local air quality authority may set specific conditions for operation during that period. A temporary source shall be required to comply with all applicable emission standards.

**Greenhouse Gases**

Greenhouse gases are gases that trap heat in the atmosphere, and are implicated in potential global climate change. Some greenhouse gases such as carbon dioxide occur through both natural processes and human activities. Other greenhouse gases (e.g., fluorinated gases) are
created and emitted solely through human activities. The most abundant greenhouse gasses are water vapor, carbon dioxide, methane, nitrous oxide, ozone and chlorofluorocarbons\(^4\). However, because different gasses have different heat-trapping effects, the most abundant greenhouse gasses are not necessarily the largest contributors to potential climate change.

Greenhouse gases are discussed in this section because in the United States, energy-related activities account for 75 percent of human-generated greenhouse gas emissions, mostly in the form of carbon dioxide emissions from burning fossil fuels. Half of all emissions from energy-related activities come from large stationary sources such as power plants (USEPA 2009).

Largely because of the contribution of hydropower, energy generation in the Pacific Northwest, including the Federal Columbia River Power System, produces less carbon dioxide per MW-hour than any other region in the United States. The Federal Columbia River Power System alone produces about 7,000 average MW of hydro-electricity even in a dry water year, enabling the region to sustain its relatively small carbon footprint.

Like hydropower, production of electricity from wind produces no direct emissions of greenhouse gasses or other air pollutants. The generation of wind energy also displaces generation from individual fossil-fuel-fired power plants or units, thereby reducing fuel consumption and the resulting air emissions that would have otherwise occurred.

**State Regulation of Greenhouse Gasses**

In Washington State, greenhouse gasses are regulated by RCW Chapter 80.80, which establishes goals for statewide reduction of greenhouse gas emissions. The statute aims to reduce overall greenhouse gas emissions to 1990 levels by 2020, and to 25 percent below 1990 levels by 2035. By 2050, the state intends to reduce overall emissions to fifty percent below 1990 levels. Goals also include fostering a clean energy economy by increasing the number of jobs in the clean energy sector to 25,000 by 2020, from just over 8,000 jobs in 2004. Ecology has proposed regulation (Chapter 173-441 WAC)\(^5\), which would establish an inventory of greenhouse gas emission through a mandatory greenhouse reporting rule for owners or operators of:

- A fleet of on-road motor vehicles that as a fleet emit at least 2,500 metric tons of greenhouse gases annually in the state
- A source or combination of sources that emit at least 10,000 metric tons of greenhouse gases annually in the state

Since wind power projects would not emit greenhouse gasses during operations, these regulations are unlikely to apply to the Project.

**Bonneville Power Administration Greenhouse Gas Initiatives**

In 2008, BPA adopted new initiatives related to climate change, and included the issue in their strategic objectives and key agency performance targets. One of BPA’s first steps was to prepare

an initial climate change roadmap (BPA 2008)\(^6\) intended as a step toward subsequent, more robust plans for managing greenhouse gas emissions. This document identifies near-term and long-term potential actions to meet agency targets and contribute to national and regional greenhouse gas reduction goals. As a first step in managing greenhouse gas emissions, BPA has collected data in 2009 to inventory BPA’s greenhouse gas footprint, which were reported in 2010.

**Background Air Quality**

The Dalles, Oregon is the closest city with an air monitoring station. The Oregon Department of Environmental Quality (ODEQ) reports air quality data using an air quality index based on particulate matter 2.5 micrometers diameter and smaller (PM\(_{2.5}\)). ODEQ’s 2008 report for The Dalles shows 339 days with good air quality, 25 days with moderate air quality, and no days with unhealthy air quality (ODEQ 2009).

While air quality in the Project Area is generally good, haze is a well-documented problem in the Columbia Gorge and the causes are being studied by the Southwest Clean Air Agency. In a 2008 Report, the agency found that haze was largely caused by winter stagnations that trap pollutants and fog (SWCAA 2008). In the summer, winds flow predominantly from the west, transporting emissions from the Portland metropolitan area into the Gorge. Wildfires also contribute to the haze when smoke is blown into the Gorge. There is no single source that is primarily responsible for haze; however, man-made sources are important contributors (ODEQ 2008). The most significant man-made sources contributing to haze in the Gorge include:

- Power plant emissions
- Woodstoves
- Motor vehicles
- Non-road emissions (e.g. ships, trains, trucks)
- Agricultural sources of ammonia

The Skamania Fish Hatchery, located west of the Project Area, collected climatological data in the Project Area for 1965–2005. Average temperatures ranged from a minimum of 38.2 degrees Fahrenheit to a maximum of 61.8 degrees Fahrenheit. Average precipitation was 84.06 inches, and there was an average of 9 inches of snow per year.\(^7\)

---

3.2.2 IMPACTS

3.2.2.1 Proposed Action

The potential environmental consequences of the proposed Project include those from construction and operation. Impacts to air quality would not differ between the two alternative locations for the Operations and Maintenance Facility. Potential impacts include emissions, odors and dust.

**Construction**

**Emissions**

Construction of the Project would result in temporary air emissions from the following sources:

- Exhaust from the diesel construction equipment used for Project Area preparation (including logging), grading, excavation, and construction of on-site structures
- Exhaust from water trucks used to control construction dust emissions
- Exhaust from diesel trucks used to deliver equipment, concrete, fuel, and construction supplies to the construction site
- Exhaust from pickup trucks and diesel trucks used to transport workers and materials around the construction site and from vehicles used by workers to commute to the construction site
- Exhaust from diesel-powered welding machines, electric generators, air compressors, etc.
- Emissions from one or more portable rock crushers and one or more portable concrete batch plants, which would be used as necessary to supply the large amounts of gravel and concrete needed for the Project

The primary air pollutants from diesel-powered equipment would be nitrogen oxides, hydrocarbons, carbon dioxide, particulate matter (PM) and sulfur dioxide. In addition to these, the rock crusher and batch plant(s) would produce additional PM. These emissions would be similar in nature to those produced by any construction project that involves heavy equipment and transportation of materials to the Project Area. These construction emissions would be temporary and would be limited to the areas adjacent to the construction site. They would not affect a substantial number of persons or persist for an extended period of time and would not result in exceedance of any air quality standards.

**Odors**

Project construction would produce limited odors associated with exhaust from diesel equipment and vehicles, and painting the Operations and Maintenance facility, turbine towers, and other structures. The effect of odors would be temporary, and would be limited to the areas adjacent to the construction site and along haul routes to the batch plant(s) and rock crusher. Odors would not affect a substantial number of persons or persist for an extended period of time. An
occasional small amount of diesel exhaust may be noted from trucks entering or leaving the site from public roadways.

**Dust**

Project construction would create fugitive dust from construction and re-construction of gravel roads, including from rock crushing and/or a concrete batch plant. Small amounts of dust would be created by construction-related traffic and additional wind-blown dust as a result of ground disturbance. The presence and impact of dust would be temporary, and would be limited to areas adjacent to the construction site and along haul routes. Dust would not affect a substantial number of persons or persist for an extended period of time. A small amount of dust may be noted from trucks entering or leaving the site from public roadways.

**Operation**

**Emissions**

Since the fuel source for the proposed Project would be wind, there would no emissions from the operation of the turbines. Project operation would not produce visible plumes, fogging, misting, icing, or impairment of visibility, or changes in ambient levels of pollutants. Emissions would occur from Operations and Maintenance vehicles. Travel on the Project access roads would produce minor exhaust emissions.

**Avoided Emissions**

Project operation would avoid the use of fossil fuel to meet the energy needs of the region. The Project’s annual electricity production is estimated at 197,000 megawatt hours (MWh). This energy is equivalent to 114,000 barrels of crude oil or 654 million cubic feet of natural gas. Total electricity production can be used to estimate the emission displaced by a fossil-fuel alternative. Table 3.2-1 shows emission rates for carbon dioxide and sulfur dioxide for fossil-fuel-based power plants in the Northwest Power Pool, along with estimated emissions avoided from the operation of the wind power plant. This table also shows the displaced emissions from the Project as a percentage of Washington State emissions for 2004.
Table 3.2-1

* Non-baseload output emission rates for Northwest Power Pool Western Electric Coordinating Council Northwest Region. A non-baseload emission factor was used to calculate the avoided emissions from the Project, based on guidance from the US Environmental Protection Agency that “Annual non-baseload output emission rates … can be used to estimate GHG emissions reductions from reductions in electricity use. These output emission rates, called annual non-baseload emission rates, are the annual output emission rates for plants that combust fuel and have capacity factors less than 0.8. These new data values are derived from plant level data and supplement, rather than replace, the fossil fuel output emissions rates, which are sometimes used as a rough estimate to determine how much emissions could be avoided if energy efficiency and/or renewable energy displaces fossil fuel generation. These non-baseload output emission rates would somewhat improve this rough estimate by factoring out baseload generation, which is generally unaffected by measures that affect marginal generation” (USEPA 2007).

b Estimated annual electricity production multiplied by emission rate, for example, for carbon dioxide (1,334) x [(75 MW) x (0.30 capacity factor) x 24 x 365]/2000 = 131,465.7 tons

c 2005 value; values for 2005 were not available for the other pollutants listed.

By avoiding the need for fossil-fuel-powered plants, the Project would contribute to air quality by avoiding emissions associated with burning fossil fuels, including greenhouse gasses. Using wind power also likely would have a beneficial effect on visibility, since the same pollutants that affect visibility also affect air quality (ODEQ 2008).

Greenhouse Gas Emissions from the Project

Greenhouse gases would be emitted during construction of the Project, as a result of burning fossil fuels in the construction equipment and vehicles. The amount of these emissions has not been quantified, but would be directly proportional to the number of workers and vehicles on the site. Some emissions of greenhouse gases would take place during the design, manufacture, transport of the wind turbines. During operation, greenhouse gas emissions would be the result of vehicles used for regular maintenance activities and would be much lower than during construction. Production of electricity itself would not release greenhouse gasses or other pollutants. The American Wind Energy Association estimates that including generation from all sources, wind energy’s carbon dioxide emissions are on the order of 1 percent of coal or 2 percent of natural gas per unit of electricity generated (AWEA 2009).

While greenhouse gas emissions from the Project would be low, several of the mitigation measures mentioned in Section 3.2.3 would reduce such emissions. These include limiting idling times of equipment and encouraging carpooling among construction workers.

Odor

Operation of the turbines would create no odors, as no combustion is involved and no odor-producing materials would be used in Project operations. Travel on the Project access roads would produce insignificant amounts of odor from exhaust. Maintenance of the substation and Operations and Maintenance building would produce occasional minor odors from painting.

Dust

Operation of the Project would result in minor increases in dust during regular maintenance of gravel access roads. Project-related increases to traffic on these gravel roads would generate
small amounts of additional fugitive dust. This increased traffic would consist largely of weekly or less frequent trips to turbines in service vehicles for maintenance and repair activities.

**Project Decommissioning**

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is suspended or terminated during construction or before it has completed its useful operating life. The plan would include or parallel a decommissioning plan for the Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential emissions or impacts to air quality. If impacts to air quality are anticipated to occur as a result of site restoration and Project decommissioning, mitigation measures would be proposed as part of the plan.

**3.2.2.2 No Action Alternative**

Under the No Action Alternative, the Project would not be built. The Project Area would continue to be used primarily for timber harvests. If the No Action Alternative is selected, the growing electricity needs of the region would continue to be met through a combination of other renewable development and combustion of additional fossil fuels. In recent years, several of the new power plants proposed and constructed in the Pacific Northwest have been fossil-fuel-powered plants, primarily using natural gas as fuel in combined-cycle combustion turbines.

Fossil fuel power plants, in contrast to wind power projects, emit significant quantities of carbon dioxide, an important greenhouse gas linked to potential climate change. Natural gas-powered plants also emit sulfur oxides and nitrogen oxides, which contribute to both ground-level air quality problems and acid rain. According to the *Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2006* (USEPA 2008), air emissions from fossil fuel combustion for electricity production are a leading source of air pollution nationally, accounting for:

- 67 percent of sulfur dioxide emissions;
- 28 percent of nitrogen oxide emissions;
- 36 percent of carbon dioxide; and
- 3 percent of mercury.

**3.2.3 MITIGATION MEASURES**

The following mitigation measures are identified to avoid, minimize, and compensate for potential construction-related air emissions and dust impacts:
• Ensure that all vehicles used during construction comply with applicable Federal and state air quality regulations.

• Implement operational measures, such as limiting engine idling time and shutting down equipment when not in use, to reduce air emissions.

• Implement active dust suppression on unpaved construction access roads, parking areas and staging areas, using water-based dust suppression materials in compliance with state and local regulations.

• Implement a dust control program to minimize any potential disturbance from construction-related dust. Dust suppression would be accomplished through application of either water or a water-based, environmentally safe dust palliative such as lignin. The use of a dust palliative such as lignin (a non-toxic, non-hazardous compound derived from trees) would result in the use of substantially less water for dust suppression and therefore less traffic from water trucks to the construction site. The final decision regarding dust suppression techniques would be made by the Construction Contractor in consultation with local authorities.

• Limit traffic speeds on unpaved Project roads to 25 mph to minimize dust.

• Encourage carpooling among construction workers to minimize construction-related traffic and associated emissions.

• Replant or gravel disturbed areas to reduce wind-blown dust.

• Implement erosion control measures to limit deposition of silt to roadways.

3.2.4 UNAVOIDABLE ADVERSE IMPACTS

The proposed Project would produce minor and temporary impacts to air quality during construction activities, similar to existing logging operations.

3.2.5 REFERENCES

3.3 WATER RESOURCES

This section describes the existing water resources in the Project Area, the potential for impacts to water resources from the proposed Project, and mitigation measures designed to minimize or avoid those impacts. Information in this section is taken primarily from the Application for Site Certification and the visual assessment completed for that document.

3.3.1 AFFECTED ENVIRONMENT

3.3.1.1 Surface Water

The Columbia River flows south of the Project Area and receives runoff via the White Salmon Basin from the east portion of the Project Area and via the Little White Salmon Basin from the west portion of the Project Area. Surface water resources in and near the Project Area are shown on Figure 3.3-1 and include the following:

One wetland labeled “Cedar Swamp” on Figure 3.3-1 and described in Section 3.4.

- Several drainages located within the Project Area boundaries, which are typed as seasonal, non-fish habitat streams or perennial, non-fish habitat streams (Figure 3.3-1). Some drainages extend upstream from these typed reaches, but lack defined channel features. Most of the drainages within the Project Area boundary would be classified as Class V streams under Skamania County’s critical areas ordinance. Class V streams are small perennials streams or seasonal streams with short periods of spring or storm runoff (SCC 21A Appendix C). The tributary to Little Buck Creek may be classified as a Class IV stream as it nears the eastern Project Area boundary. The stream information has been updated from the information contained in the Application for Site Certification with additional data from field visits.

- One unnamed perennial stream crossed by West Pit Road, the proposed access road. This stream occurs in the Little White Salmon watershed. Flow was observed through the
existing culvert under West Pit Road at the time of the July 2009 field visit. However, the surface flow and the channel disappear downstream of the culvert. There is no surface water connection to any other stream or waterbody.

3.3.1.2 Stormwater Runoff

Water runoff from the northeast portion of the Project Area drains southeast via Cedar Swamp and its tributaries to Little Buck Creek before flowing south to the White Salmon River, and ultimately to the Columbia River. Water runoff from the southwest area of the Project drains west and southwest to a flat area east of the Project, ultimately draining to the Little White Salmon River and then the Columbia River.

Project Area soils are classified as well-drained, with slow to moderate runoff, and slight to moderate hazard of water erosion. The presence of scour, sedimentation, steep slopes, ephemeral and perennial streams, and the soil classifications suggest that surface water runoff and infiltration within the Project are moderate (Haagen 1990).

3.3.1.3 Groundwater

A subsurface investigation was conducted in September 2007 to assess near-surface soil and rock characteristics (Appendix B). The investigation included twelve test pits excavated from seven to 16 feet in depth. Groundwater was not encountered in any of the test pits. However, these observations reflect groundwater levels at the time of the field investigation and actual groundwater levels may fluctuate significantly in response to seasonal effects, regional rainfall, and other factors not observed during this investigation. Regional or perched water tables may be present at a greater depth.

3.3.1.4 Floodplains

The Project Area is located on a series of north-trending ridges that range in elevation from approximately 2,100 to 2,300 feet, outside the 100-year floodplain for the White Salmon, Little White Salmon, and Columbia Rivers (FEMA 1986).

3.3.1.5 Public and Private Water Supplies

There are no public water supplies within the Project Area. Private water supplies are limited to water supply wells serving adjacent residences and agricultural operations.
Figure 3.3-1
Waterways in the Project Vicinity

Job No. 33758687

Whistling Ridge Energy Project
Conditional Use Permit Application
3.3.2 IMPACTS

3.3.2.1 Proposed Action

Construction

Surface Water

On site, Project construction would involve roadway improvements on approximately 7.9 miles of existing private, gravel logging roads, construction of approximately 2.4 miles of new gravel access roads, the Project substation, an Operations and Maintenance building at one of two alternative sites, the collector system pad, a pad for each turbine tower, and underground electric cables buried in trenches along the access roads. Temporary roadways would be built to provide additional access for heavy machinery during construction. Of these improvements, only the planned improvement to West Pit Road may directly affect water resources.

The planned improvements to West Pit Road would cross one unnamed drainage that currently flows under West Pit Road through a culvert. This drainage would be classified by Skamania County as a Class V stream. The Skamania County Code establishes buffers for Class V streams; however, expansion of existing uses is allowed within these buffers. The culvert under West Pit Road was upsized during road improvements in summer 2009. Depending on the amount of additional roadway widening that may be required, this new culvert may need to be lengthened to extend beyond the width of the improved access road. This would be determined in during final design.

Small portions of stream and stream buffer are located with the 650-foot turbine corridors used for permitting this Project. However, all streams and stream buffers would be avoided during the micrositing process.

No wetlands or other surface water bodies would be filled or otherwise affected as a result of the Project. Wetlands are discussed in further detail in Section 3.4.

Stormwater Runoff

Construction would result in approximately 108 acres of disturbed surface, of which approximately 52 acres would be restored. Use of standard construction BMPs would mitigate surface runoff and erosion from these surfaces to a minor level.

Groundwater

No impacts to groundwater are anticipated from construction. Construction water would be obtained from a supplier with valid water rights and no construction water would be withdrawn on site. Potential spills to groundwater during construction would be controlled through standard construction BMPs. A Spill Prevention, Control and Countermeasure (SPCC) Plan would be prepared.
Floodplains
The Project Area is located outside of floodplain areas. No construction impacts to floodplains would occur.

Public and Private Water Supplies
During construction, approximately 1.7 million gallons of water would be used for road construction, wetting of concrete, dust control, and other activities. Water consumed during construction would be purchased by the contractor from an off-site vendor with a valid water right and transported to the Project Area in tanker trucks. No water would be withdrawn from the Project Area during construction. There would be no water treatment requirements or methods on site. Environmentally benign dust palliatives such as lignin may be added to water used for dust suppression to improve efficiency and reduce water use.

Operation
Surface Water
No impacts to surface water are anticipated from Project operation.

Stormwater Runoff
The total Project Area is approximately 1,152 acres; however, permanently improved areas would cover approximately 56 acres, less than 5 percent of the total Project Area. Stormwater impacts from disturbed areas would be generated from this permanently improved area.

The increase in surface water runoff from this additional impervious surface is expected to be minimal. Stormwater would continue to be routed off-site via culverts and some stormwater would continue to infiltrate in the way it does currently. Based on site conditions and assuming implementation of appropriate BMPs, the net impact to absorption in the Project Area is considered negligible and there would be negligible impacts to surface water.

Approximately 22 acres would be converted from forested to non-forested habitat in the areas surrounding the turbines where re-growth of trees would be prevented. This conversion would result in minimal impacts to precipitation interception and runoff.

Groundwater
Operation of the Project would have minimal or no impacts to groundwater. The well serving the Operations and Maintenance building would use less than 5,000 gallons of water per day, and would thus be exempt from permit requirements of RCW 90.44.050 RCW 90.44.040. The size of the aquifer is not known; however, this would be the only well in the Project Area, which is approximately 1,152 acres in size. The well would be installed by a well contractor licensed pursuant to Chapter 173-162 WAC, and in compliance with the requirements and standards of Chapter 173-160 WAC. The well would be installed consistent with Skamania County Community Development Department and Ecology requirements for new wells.

Although the amount of impervious surface would increase by approximately 52 acres with the construction of the Project, impacts to groundwater recharge during operation would be negligible.
Floodplains

The Project Area is located outside of floodplain areas. No impacts to floodplains would occur from operation of the Project.

Public and Private Water Supplies

Project operation would require water use primarily for the bathrooms, showers, and kitchen in the Operations and Maintenance building. When the Project is operational, there would be eight to nine permanent full-time and/or part-time employees on the Operations and Maintenance staff. The average total water supply needs would be less than 5,000 gallons per day.

Water supply for the Operations and Maintenance staff would be provided through a well drilled within the Project Area. All water would be discharged to a septic tank installed on site, and thus most of the water used would be returned to the aquifer. There would be no process water generated on site, and no water associated with plant operations would be discharged to surface waters.

The Project would not require the use of any water for cooling or any other industrial use, and there would be no industrial wastewater stream from the Project. The Project would require and obtain approval for the new well from EFSEC, in consultation with Skamania County Environmental Health Department and Ecology.

The Project would not require any new water rights or authorizations beyond the well for the Operations and Maintenance building.

Due to the low volume of water that would be required for operational use, no alternatives to reclaim water or other water reuse projects would be required. Project water use is not expected to affect water levels in private wells in the vicinity of the Project. There are no public water supplies within the Project Area; therefore, no impacts are anticipated to public water supplies.

Project Decommissioning

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least 90 days prior to the beginning of site preparation. The plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is suspended or terminated during construction or before it has completed its useful operating life. The plan would include or parallel a decommissioning plan for the Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential changes to surface water flow, water quality, stormwater runoff, groundwater quality, or water supply. If impacts to water resources are anticipated to occur as a result of site restoration and Project decommissioning, mitigation measures would be proposed as part of the plan.
3.3.2.2 No Action Alternative

Under the No Action Alternative the Project would not be built, and there would be no well drilled to support the Operations and Maintenance building. No impacts to surface or ground water would occur.

3.3.3 MITIGATION MEASURES

The following mitigation measures are identified to avoid, minimize, and compensate for potential impacts of the proposed Project related to water resources during pre-construction, construction, and operation.

- Prepare and implement a Stormwater Pollution Prevention Plan (SWPP) prior to construction of the proposed Project to lessen soil erosion and improve water quality of stormwater run-off. The SWPP would be developed to prevent movement of sediment off-site to adjacent water bodies during short term or temporary soil disturbance at construction sites. The plan addresses stabilization practices, structural practices and stormwater management (as outlined by Section 402(p) of the Federal Clean Water Act and Chapter 90.48 RCW of the State of Washington's Water Pollution Control Act).

- Identify all areas of potential chemical storage during construction, including any herbicides, and provide appropriate control measures within the SWPP.

- Control the sequence and methods of construction activities to limit erosion. Clearing, excavation, and grading would be limited to the minimum areas necessary for construction of the Project, and would not be performed far in advance of facility construction.

- Design slopes to be graded no steeper than 3 feet horizontal (H) to 1 foot vertical (V).

- Protect slopes less than 3H:1V with silt fencing as appropriate. Silt fences would be installed in locations where they would trap silt eroded from slopes during construction and prior to reestablishing vegetation. The maximum flow path to each silt fence would be approximately 100 feet. No concentrated flows greater than 1 cubic foot per second would be directed toward any fence for the 25-year storm. Silt fences would be maintained throughout the construction period and beyond, until disturbed surfaces had been stabilized with vegetation. Silt fence construction would be determined by local construction conditions during final design of the facilities.

- Design sediment control measures used during construction based on 10-year design storm specifications. Water quality measures (other than sediment removal) would be based on the 6-month, 24-hour design storm.

- Utilize sediment traps to intercept stormwater runoff and allow sediment to settle, thereby minimizing the amount of sediment flowing off site. Sediment traps would be sized for the specific disturbed area, for bare soil conditions, and typically for 75 percent sediment removal efficiency.
• Implement and emphasize erosion controls over sediment controls through non-quantitative construction activities such as:
  - Straw mulching and vegetating disturbed surfaces;
  - Retaining original vegetation wherever possible;
  - Timing grading operations to dry seasons;
  - Directing surface runoff away from denuded areas;
  - Keeping runoff velocities low through minimization of slope steepness and length; and
  - Providing and maintaining stabilized construction entrances.

• Grade control structures such as rock check dams, hay bale check dams, dikes, and swales would be used where appropriate to reduce runoff velocity, as well as to direct surface runoff around and away from cut-and-fill slopes. Swales and dikes also would be used to direct surface water on top of the filled pad toward sediment traps and away from flowing over the bank.

• Utilize the appropriate erosion control blankets designed for various weather conditions during the construction period, such as straw or jute matting or other suitable erosion control blankets, on any disturbed slopes to prevent erosion and control sediment migration.

• Use quarry spall construction entrances to reduce migration of construction dirt to public roads. Placing the construction entrances is one of the first activities required at the site, but the rock bed also must be periodically replenished as it becomes dirty or migrates into the subgrade. All construction traffic would be directed to use the construction entrances.

• Restore ground surfaces within fourteen days of the area’s final disturbance. Interim surface protection measures, such as erosion control blankets or straw matting, also may be required prior to final disturbance and restoration if warranted by the potential for erosion.

• Reduce potential for chemical pollution of surface waters during construction. Since source control is the most effective method of preventing chemical water pollution, careful control must be exercised over potentially polluting chemicals used on site during construction. Under the SPCC Plan, the general contractor would be responsible for planning, implementing, and maintaining BMPs for:
  - Neat and orderly storage of construction chemicals and spent containers in lined, bermed areas;
  - Prompt cleanup of construction phase spills; and
  - Regular disposal of construction garbage and debris.

• Train employees to utilize methods outlined by the SWPP.
• Dispose and contain garbage generated during construction properly.

• Design and incorporate BMPs into final construction plans and specifications so that operational impacts to water resources would be minor.

• Construct appropriate stormwater hydraulic and treatment facilities making sure that routine maintenance and chemical pollution prevention through source control are utilized for permanent stormwater management.

• Utilize the following constructed permanent stormwater BMPs:
  - Vegetated drainage ditches;
  - Culverts with stabilized inlets and outlets;
  - Permanent erosion and sedimentation control through site landscaping, grass, and other vegetative cover; and
  - Runoff treatment BMPs facilities would be designed to conform to the applicable Stormwater Management Manual.

• Adopt operational BMPs to implement good housekeeping, preventive and corrective maintenance procedures, steps for spill prevention and emergency cleanup, employee training programs, and inspection and record keeping practices as necessary to prevent stormwater pollution. Examples include:
  - Neat and orderly storage of chemicals under cover in the Operations and Maintenance facilities;
  - Prompt cleanup and removal of spillage;
  - Regular pickup and disposal of garbage and rubbish; and
  - Prevention of accumulations of liquid or solid chemicals on the ground or the floor.

• Train facility operators annually to in spill response and in the applicable pollution control laws and regulations.

• Train additional staff to recognize areas that may be affected by a spill and potential drainage routes.

• Train additional staff to report spills to appropriate individuals.

• Train additional staff on the appropriate material handling and storage procedures.

• Train additional staff to implement spill response procedures.
• Summarize in-house compliance inspections to be kept with the SWPP, along with any notifications of non-compliance and reports on incidents such as spills. If the SWPP has been followed but still proves inadequate to prevent stormwater pollution, Project staff would amend the SWPP and seek EFSEC concurrence with the improvements.

• Utilize BMPs to include vegetated ditches or swales which would increase infiltration to protect groundwater.

• Utilize a site development plan to protect groundwater from the on-site storage of chemicals (if any).

3.3.4 UNAVOIDABLE ADVERSE IMPACTS

Construction and operation of the Project would only result in negligible to minor impacts to water resources because the impacts are localized and the disturbance is short-term.

3.3.5 REFERENCES

3.4 BIOLOGICAL RESOURCES

This section describes the existing biological resources in the Project Area, including vegetation, habitat, wetlands, special status species, fish and other wildlife. It also considers the potential for impacts to biological resources as a result of construction and operation of the Project, and mitigation measures designed to minimize those impacts. Information in this section is taken from the following background studies and reports:

• Vegetation Technical Report: Saddleback Wind Project (CH2MHiI, no date) (Appendix C-1);

• Wetland Delineation Report, Saddleback Wind Energy Project (CH2MHill 2007) (Appendix C-2);

• Rare Plant Survey Report: Saddleback Wind Project (CH2MHill 2003) (Appendix C-3);

• Baseline Avian Use Surveys of the Project in Fall 2004, Summer 2006, and winter-spring 2008-2009 (West Inc. 2009a) (Appendix C-4);

• Final Report, Northern spotted owl, western gray squirrel and northern goshawk surveys conducted for the Whistling Ridge Wind Energy Project (Turnstone 2004) (Appendix C-5);
• 2008 Final Report, Results of northern spotted owl, western gray squirrel and northern goshawk surveys conducted for the Whistling Ridge Wind Energy Project. (Turnstone 2008) (Appendix C-6);

• 2009 Report, Results of northern spotted owl, western gray squirrel and northern goshawk surveys conducted for the Whistling Ridge Wind Energy Project. (Turnstone 2009) (Appendix C-7);

• Bat Acoustic Studies for the Whistling Ridge Wind Resource Area in 2007 (West Inc. 2008; Appendix C-8), 2008 (West Inc. 2009b; Appendix C-9), and 2009 (West Inc. 2009c; Appendix C-10);

• Revised Report, Analysis of Cumulative Impacts on Avian, Bat and Habitat Associated with Wind Energy Development in the Columbia Plateau Ecoregion of Eastern Washington and Oregon (WEST 2010; Appendix C11) prepared for Klickitat County;

• Washington Natural Heritage Program (WNHP 2003a, 2003b, 2009);

• Discussions with representatives of Washington Department of Fish and Wildlife and USFWS;

• Supplemental wetland reconnaissance and special status plant surveys in May and July 2009;

3.4.1 AFFECTED ENVIRONMENT

3.4.1.1 Regional Environment

The Project Area is located in the Southern Washington Cascades Province, within the grand fir (Abies grandis) and Douglas-fir (Pseudotsuga menziesii) major vegetation zones (Franklin and Dyrness 1988). Topography in the area is characterized by generally accordant ridge crests, separated by steep, deeply dissected valleys. The prevailing climate is cool and wet. The majority of precipitation falls as snow, which may accumulate one to three meters during the winter season. The site is located on Underwood Mountain. Major drainages in the vicinity of the Project Area include the White Salmon Basin to the east and the Little White Salmon River Basins to the west, both of which drain to the Columbia River, which is located south of the Project Area.

Historically, the Project Area was dominated by grand fir and Douglas-fir. The relative abundance of each of these coniferous species was driven by elevation, aspect, underlying soil, and previous disturbance history (Franklin and Dyrness 1988). Mixed conifer and deciduous forest stands were present, typically following natural disturbance events. Deciduous forests also were present, composed mainly of alder (Alnus rubra, A. viridis ssp. sinuata), Pacific dogwood (Cornus nuttallii), and big-leaf maple (Acer macrophyllum).

For the last century, the predominant land use in the area located between Underwood Mountain and the Little White Salmon River has been commercial forest production. Lands within the Project Area are privately owned, and have been actively-managed for timber for the last
century. As a result of ongoing timber harvest, forests within the Project Area are now characterized by a mosaic of stand ages; however, average stand age has declined as a result of relatively short stand rotations.

Changes in stand structure and complexity, patch size, and species distribution also have occurred. Forest management practices have resulted in a shift in species dominance to the commercially valuable Douglas-fir. Few large, old-growth conifers exist in the Project vicinity, and there are no late-successional stands or old forest habitats (using Washington Forest Practices habitat definition) within or adjacent to the site. Canopy species within the corridor areas have been removed, and areas are managed to be devoid of shrub and tree species.

The proposed turbine corridors have been forested recently in general conformance with established timber harvest schedules, and are connected by a network of existing forest roads. Four major BPA high voltage transmission lines, located in two corridors, cross the site. Canopy species within these two corridors have been removed, and areas are managed to be devoid of shrub and tree species. The Project Area contains a network of roads ranging in width from approximately 8 to 20 feet. These roads are currently used to support logging activity and to access BPA transmission lines.

A Williams Northwest natural gas pipeline is located on the northern edge, their natural compressor station is located to the west, and cellular towers and communications facilities are located nearby. Resource mining in the area has left rock pits in places. As a result, the Project Area includes only heavily managed native habitat and is permanently committed to use by commercial forestry operations and utility infrastructure no native habitat and is permanently committed to use by commercial forestry operations and utility infrastructure.

Initial habitat, vegetation, and special status plant surveys were conducted within the Project Area in 2003. Environmental assessments included a pre-field information review and field surveys designed to classify habitats and identify special status plants that may occur within the Project Area. Supplemental habitat, vegetation, and special status plant surveys were conducted in 2009.

3.4.1.2 Habitats

Habitat maps were created using DNR orthophotos from January 2002 and classified using the USFS Classification System (USFS 1985). Habitat maps were field-verified during the 2003 survey season. These data were entered into a GIS database and used to calculate the total acres of each habitat type that would be crossed by the proposed Project elements. The results of the habitat survey are provided in the Vegetation Technical Report (Appendix C-1).

8 “Adjacent” refers to defined as non- Applicant lands that were within 1.8 mile of the proposed turbine strings and/or the two known northern spotted owl management areas (Mill and Moss Creek) north of the Project Area.
Five vegetation communities and wildlife habitats were identified within the Project Area:

- Grass-forb stand (recent clearcuts);
- Brushfield/shrub stand;
- Conifer-hardwood forest;
- Conifer forest; and
- Riparian-deciduous forest.

All five of the vegetation communities are part of a mosaic of habitat that comprises a commercial forest operation, as discussed in Section 3.4.1.1. Because of these man-made conditions, which result in frequent and repeated disturbance, the quality and value of the forest is generally considered low. Native tree species are used in timber production; however, they are not allowed to become mature forests prior to harvesting. Stand structure also is considered to be low quality with limited undergrowth of a few species. Weeds are present, especially in clear cuts, which are eventually cleared for regeneration. Patch size of forests are generally small, and bisected by numerous roads, transmission lines and other facilities for logging. Timber harvest rotations are ongoing; therefore, future quality of the habitat in the Project Area is also considered low.

**Grass-Forb Stand**

Grass-forb stands are defined as habitats where shrubs comprise less than 40 percent crown cover and are less than 5 feet tall (USFS 1985). This stand type typically occurs when a natural or anthropogenic disturbance such as a wildfire, wind, or timber harvest results in the removal or death of the majority of large trees, or when brushfields are cleared for planting. These habitats may be devoid of vegetation, or covered by herbaceous grasses and forbs. Tree regeneration in grass-forb stands is typically less than 5 feet tall and 40 percent crown cover. Grass-forb stands within the Project Area are located primarily in recently clearcut harvest areas. Vegetation in these areas is minimal and consists predominantly of weedy herbaceous species, including bull thistle (*Cirsium vulgare*), Canada thistle (*Cirsium arvense*), and dandelion (*Taraxacum officinale*). Coarse woody material, occasional slash piles, and large areas of bare ground are common in these areas.

**Brushfield/Shrub Stand**

Brushfields are defined as the shrub-dominated habitats (USFS 1985). These habitats typically develop following clearcut harvest, or natural disturbance that may result in removal of vegetation.

The majority of brushfields are young plantations that have been planted with Douglas-fir. The plantations typically have not reached the closed-canopy stage. Vegetation consists of remnant forest understory species, such as vine maple (*Acer circinatum*), Sitka alder, beaked hazelnut (*Corylus cornuta var. californica*), serviceberry (*Amelanchier alnifolia*), oceanspray (*Holodiscus discolor*), bracken fern (*Pteridium aquilinum*), sword fern (*Polystichum munitum*), and early
successional species such as Himalayan blackberry (*Rubus armeniacus*), fireweed (*Epilobium angustifolium*), common yarrow (*Achillea millefolium*), pearly everlasting (*Anaphalis margaritacea*), and grasses. Large amounts of bare soil, slash and other logging debris are common.

Vegetation control has occurred in some areas as part of existing forest management practices. Control methods include herbicide application and/or mechanical control. Areas where vegetation management has occurred are visually and functionally different from areas where control has not been implemented. In areas where vegetation control has not occurred, dense vine maple thickets with occasional alder or Douglas-fir frequently occur. Patches of alder saplings, salmonberry (*Rubus spectabilis*), vine maple, red elderberry (*Sambucus racemosa*), oceanspray, lupine (*Lupinus* spp.), Oregon oxalis (*Oxalis oregana*), and grass also may be present in these areas. Small diameter coarse woody material is common.

**Conifer-Hardwood Forest**

Conifer-hardwood forests within the Project Area are predominantly characterized by the presence of bigleaf maple and Douglas-fir, with some red alder. The forest stand condition is characterized as a multi-layer, closed sapling-pole forest (USFS 1985). Canopy height ranges from 40 to 60 feet, and canopy closure is between 60 and 80 percent. The majority (~70 percent) of canopy cover results from the presence of Douglas-fir. The shrub layer is characterized by vine maple, salmonberry, thimbleberry (*Rubus parviflorus*), red elderberry, beaked hazelnut, and Pacific dogwood. Density of the shrub layer is variable. The herbaceous layer is characterized by sword fern, trailing blackberry (*Rubus ursinus*), oxalis, grasses, and moss. Coarse woody material is generally low to moderate. Deciduous snags are more common than conifer snags; however, short well-decayed conifer snags may be present.

**Conifer Forest**

Coniferous forests located within the Project Area are dominated by grand fir and Douglas-fir. Forest stand condition is primarily closed sapling-pole-sawtimber and large sawtimber. The diameter at breast height of pole-size conifers measures 8–12 inches. The diameter at breast height of sawtimber measures 12 to 23 inches. Closed sapling-pole-sawtimber stands are characterized by closed canopy, relative short live crowns, and exclusion of shrub species and many forb species. Coarse woody material in these stands is typically low, consisting mainly of remnants from historic forests. Snags are rare; however, small diameter snags become more common in the pole and sawtimber stages, as smaller individuals are out-competed.

Large sawtimber is considered to be at least 21 inches diameter at breast height. Large sawtimber stands are characterized by within-stand differentiation of canopy species, the emergence of dominant trees, and a more diverse and multilayer understory composed of shrubs and forbs. Snags and coarse woody material are generally rare; however, this may vary depending on past harvest practices, stand management, and actual stand age. The conifer forest within the Project Area is managed for commercial timber production and is replanted following harvest. The majority of coniferous forests within the project site is managed for commercial timber production, and is replanted following harvest. Commercial timber lands are widespread throughout the vicinity of the Project Area.
Riparian Deciduous Forest

Riparian deciduous forests may develop in near-stream areas as a result of natural or anthropogenic disturbance. Riparian deciduous forest habitats are present within the Project Area in an area known as “Cedar Swamp.” Historically this area was dominated by large, old-growth western redcedar (*Thuja plicata*); however, these trees have since been harvested. Cedar Swamp is now dominated by willow (*Salix* sp.) and cottonwood (*Populus balsamifera*), with scattered occurrences of young western redcedar. Cedar Swamp is discussed further in Section 3.4.1.3.

The vegetation communities described above are common throughout the Southern Washington Cascades Province. In the proposed Project Area, these communities are maintained primarily through forest management. Because the Project is located within private commercial timber lands, existing forest management practices are expected to continue for the foreseeable future. The total acreage of each habitat type was calculated during the 2003 surveys; however, because of active forest rotation schedules, some of these areas have been harvested. Aerials photos from 2009 were used to update the habitat maps from 2003 with recent timber harvests (Figure 3.4-1). The updated acreages of each habitat type can be found in Table 3.4-1.

Grass-forb, brushfield/shrub, and conifer forest habitat types are present along West Pit Road. However, the band along the road that is within the Project bounds is too narrow to map on Figure 3.4-1.

In addition, the Washington Department of Fish and Wildlife (WDFW) Priority Habitats and Species database was searched for the area in and around the Project Area. No sensitive habitat features such as snags, talus, or Oregon white oak were identified in or within one mile of the Project Area. The Project Area is not located within any known wildlife corridor, flyway, foraging area, or migratory route.
Figure 3.4-1

Habitat Types

Source: GeoDataScape.
3.4.1.3 Wetlands

No wetlands or wetland indicators were identified within the Project study area (the turbine corridors and proposed access roadways). One wetland was identified outside the study area perimeter west of turbines C1-C4 (Figure 3.4-2). This wetland is labeled as “Cedar Swamp” on the USGS map and is listed as palustrine unconsolidated bottom, semi-permanently flooded, impounded (PUBFh) on the National Wetland Inventory (NWI) (Appendix C-2).

Cedar Swamp is classified as a Category II wetland according to the Washington State Wetland Rating System for Eastern Washington (Ecology 2004). The standard wetland buffer for Category II wetlands enforced by Skamania County is 100 feet. The Cedar Swamp wetland is over 150 feet from the nearest proposed turbine string or proposed road, which meets Forest Practice requirements.

A preliminary review of the NWI was conducted for the area encompassing the construction access. Results indicate that wetlands occur along SR 14 near White Salmon, Washington (Figures 3.4-3a and 3.4-3b). The NWI does not show the presence of wetlands along any of the local secondary and forest roads proposed to be used by the Project. As the NWI is based on historic aerial photography interpretations, field investigations were conducted in May and July 2009. These investigations confirmed that wetlands do not occur along the local secondary and forest roads. See Section 3.3 for a discussion of surface water features such as streams.

3.4.1.4 Special Status Plant Species

Several sources were used to identify special-status plants that have been documented or have the potential to occur within the vicinity of the proposed Project, including:

- Listed and Proposed Endangered and Threatened Species and Critical Habitat; Candidate Species; and Species of Concern in Skamania County (USFWS 2009a);
- A Washington Natural Heritage Program (WNHP) record search of known special status plant locations in the vicinity of the Project Area (WNHP 2003a and 2009);
- Rare Plant List for Skamania County (WNHP 2003b and 2009).

These data indicated that no federal-listed plant species are known to occur in the vicinity of the Project Area. However, four WNHP sensitive plants occur within 2 miles of the Project Area, including branching montia (*Montia diffusa*), Suksdorf’s desert parsley (*Lomatium suksdorfii*), Siskiyou false hellebore (*Veratrum insolitum*), and golden chinquapin (*Chrysolepis chrysophylla*). Two additional special status plant species are reported as historically occurring in the vicinity of the Project Area, including bolandra (*Bolandra oregana*) and white-top aster (*Sericocarpus rigidus*). Three occurrences of the Oregon white oak/Idaho fescue (*Quercus garryana/Festuca idahoensis*) vegetation community, a WNHP high-quality plant community, are documented within 2 miles of the Project Area (WNHP 2003a and 2009). These are located along the Columbia and White Salmon Rivers.
Figure 3.4-2
Project Site Wetland

Whistling Ridge Energy Project
Skamania County, Washington
Initial surveys were conducted in May and June 2003, and followed methods described in the US Bureau of Land Management Survey Protocols for Survey and Manage Strategy 2 Vascular Plants (Whiteaker et al. 1998). Survey dates were selected to encompass all or a portion of the blooming times of all special status plants potentially occurring in the Project Area. Surveys were conducted within a 300-foot corridor centered on proposed turbine strings and associated access roads, and a 100-foot corridor centered on existing roadways that were identified as needing improvement (Figure 3-4-4). Special status plant surveys also were conducted in proposed locations for the Operations and Maintenance facility, substation, and staging areas.

During the 2003 surveys, no special status plant species or plant communities were detected in the Project Area. A detailed account of survey methods and results, as well as a list of plant species observed during vegetation surveys, can be found in Appendix C-3.

Because turbine locations were changed from the initial alignment, field surveys conducted prior to the March 2009 Application submittal did not cover 100 percent of the proposed Project Area. Additional surveys were conducted in May and July 2009 to supplement the previous studies and included West Pit Road and underground cable routes where potential special status plant habitat could exist (Figure 3.4-4). During this survey, two WNHP Watch List species were observed within the Project Area: phantom orchid (*Cephalanthera austiniae*) and gnome plant (*Hemitomes congestum*). Watch List species are afforded no protection by any agency. Most species on the Watch List are no longer actively tracked because they were found to be more abundant than previously thought.

### 3.4.1.5 Special Status Wildlife Species

Seven special-status wildlife species are known to occur within the vicinity of the proposed Project: bald eagle (*Haliaeetus leucocephalus*), golden eagle (*Aquila chrysaetos*), northern goshawk (*Accipiter gentilis*), pileated woodpecker (*Dryocopus pileatus*), Vaux’s swift (*Chaetura vauxi*), olive-sided flycatcher (*Contopus cooperi*), and western gray squirrel (*Sciurus griseus*). One species, the northern spotted owl (*Strix occidentalis caurina*), has been surveyed extensively within the Project Area and never detected and is therefore considered not to occur. Two additional special status species, Keen’s myotis (*Myotis keenii*) and Townsend’s big-eared bat (*Corynorhinus townsendii*), may occur but have not been identified in prior surveys. These species are summarized in Table 3.4-2. This section provides a detailed account of each species, their status within the Project Area, and a summary of surveys conducted within the Project Area.

**Bald Eagle**

The bald eagle is a state and federal species of concern, and also protected under the Bald Eagle Protection Act of 1940 (16 United States Code [USC] 668-668d, 54 Stat. 250) which prohibits the taking, possession and commerce of such eagles. In Washington, bald eagles are year-round residents. In addition, many bald eagles from northern areas migrate south to Washington during the winter. In Washington they occur generally in coastal waters or near large inland lakes or rivers. They are considered “fairly common” during the winter near the Project Area, but likely occur nearby year round (BirdWeb 2009). The Columbia River is approximately two miles south of the Project Area, and the White Salmon River is approximately three miles east of the Project Area. These are the two nearest likely foraging locations for bald eagles. One bald eagle was recorded in the Project Area in 2009 during surveys for northern goshawk. In addition, three bald eagles were observed during the winter of 2008–2009 during baseline avian surveys. Two were observed flying within the rotor-swept area, and one below.

**Golden Eagle**

The golden eagle is a Candidate under the Endangered Species Act and also protected under the Bald Eagle Protection Act of 1940 (16 USC 668-668d, 54 Stat. 250) which prohibits the taking, possession and commerce of such eagles. In Washington, golden eagles are year-round residents, primarily in the eastern part of the state. The Project Area is at the westernmost edge of their year-round distribution, where they are considered “uncommon” (BirdWeb 2009).
Golden eagles require open areas with large, rocky cliffs or large trees. They are often found in alpine parkland and mid-elevation clear-cuts, as well as shrub-steppe area and open forests. Although they soar at high altitudes, they drop down to the ground to capture prey. They prey on mid-sized mammals such as marmots, rabbits, ground squirrels, and birds.

Two golden eagles were recorded during the fall of 2004. The timing of this observation was consistent with localized or longer distance migration of this species in the fall. One was observed flying at a height within the rotor-swept area, and one was observed flying above the rotor-swept area. None were recorded during the summer of 2006 during baseline avian studies in the Project Area, which is consistent with the Project Area being outside of the species breeding distribution.

**Northern Goshawk**

The northern goshawk is categorized as a “species of concern” by the USFWS, and as a “listing candidate” for sensitive, threatened or endangered species by the State of Washington. Goshawks inhabit a wide variety of forest habitats, including true fir (red fir, white fir, and subalpine fir), mixed conifer, lodgepole pine, ponderosa pine, Jeffrey pine, montane riparian deciduous forest and Douglas-fir. Goshawk nest sites tend to be associated with patches of relatively large, dense forest; however, home ranges often consist of a wide range of forest age classes and conditions. Nest sites tend to be positively correlated with proximity to water or meadow habitat, forest openings, level terrain or “benches,” northerly aspects and patches of larger, denser trees, although variation in habitat associations does occur (USFS 2002). Although they inhabit and hunt dense forest sites, they also hunt in open areas. They hunt on the wing, and by swooping down on ground-dwelling prey.

In Washington State, goshawks occur year-round and in some areas only during the non-breeding seasons. The Project Area is located in an area where either may occur, and the eastern slope of the Cascades is considered the most common place to find this “uncommon” species (BirdWeb 2009). This species is generally non-migratory. Some birds move to lower elevations in the winter.

Northern goshawks were recorded during avian surveys during the fall of 2004 and the summer of 2006. A total of five individuals were sighted; two during the fall and three during the summer (Figure 3.4-5). They were observed flying both within and above the rotor-swept height during surveys. Results of these surveys are detailed in Appendix C-4.

In response to the baseline data, and in order to better understand these sightings, the Applicant commenced multi-year, species- and season-specific biological surveys for Northern Goshawk. These surveys were developed based on best available survey protocols described below, and in consultation with WDFW. Northern goshawk surveys were conducted during the spring and summer seasons in 2004, 2008, and 2009, which are the time of year when goshawks would be most expected to occur. Surveys occurred on properties managed by the Applicant, Broughton Lumber and adjacent private land.

In 2004, protocol-level surveys were conducted in suitable habitat located in four core Project sections, including the provincial home range radius of 0.5 mile around the core area (see Map 7, Appendix C-5). Suitable habitat was identified using topographic maps and aerial photography.
Survey stations were established at 0.2-mile intervals on roads and trails located in suitable habitat within 0.5 mile of a proposed wind turbine location. Potential goshawk habitat was surveyed in accordance with “Survey Methodology for Northern Goshawks in the Pacific Southwest Region” (USFS 2002). Two rounds of surveys were completed, including 185 calling stations each time. All raptor species responses detected during surveys also were recorded. No Northern Goshawks were recorded during the 2004 surveys. Detailed methodology and results for northern goshawk surveys can be found in Appendix C-5.

In 2008, the potential survey area for the northern goshawk was determined by protocol parameters outlined in the Northern Goshawk Inventory and Monitoring Technical Guide (USFS 2006), consultation with WDFW biologists, and GIS analysis. The survey area was established by placing a 150-foot buffer around the turbine string layout, and then adding an additional 2,624 foot buffer per protocol (see map in Appendix C-6). Forest stands with greatest potential to contain suitable habitat structure and composition to support northern goshawk were identified using GIS data and aerial photographs. Criteria for selecting stands included stand age greater than 25 years, and an average tree diameter at breast height of at least 12 inches. Based on these criteria, 1,100 acres was identified for surveys (Figure 3.4-5).

It was determined that the “Broadcast Acoustical Survey” methodology would be used for a two-year survey effort (2008 and 2009). Biologists completed two protocol surveys at 136 calling stations during the 2008 goshawk survey season. The first survey was conducted during the nesting period, and the second during the fledgling period. No northern goshawk responses were documented during either of the two site visits in 2008. In 2009, in addition to the two rounds of Broadcast Acoustical Surveys, two rounds of “Intensive Search” surveys were completed. These surveys were conducted where the turbine alignment extended north from prior project design. No goshawks were recorded during either type of surveys in 2009. Detailed methodology and results for 2008 can be found in Appendix C-6. The full methods and results for the 2009 surveys can be found in Appendix C-7.

**Northern Spotted Owl**

The Applicant conducted surveys and analysis to determine northern spotted owl occupancy. The Applicant conducted surveys and analysis to confirm the absence of northern spotted owls or spotted owl activity centers in the vicinity of the proposed project. Additionally, the Applicant coordinated and met with USFWS regarding its surveys and analysis for the northern spotted owl.

On April 9, 2009, the Applicant met with the USFWS to discuss the proposed Project. On May 14, 2009, the USFWS met the Applicant at the site for a site visit. On July 13, 2009 and September 14, 2009, the Applicant met with USFWS to further discuss the studies that have been performed for northern spotted owl. This section documents all the information that the Applicant obtained from its discussions with USFWS, and the surveys and analysis conducted by the Applicant.
Figure 3.4-5
2008-2009 Northern Goshawk Survey Locations

Whistling Ridge Energy Project
Conditional Use Permit Application
A total of 9 turbines are proposed within the 1.8 mile provincial range of two northern spotted owl activity centers. There are no proposed turbines located within the 500 acre core areas of these activity centers. Two historical meeting sites on public lands near the property have not been used in over six and eight years, respectively, and are no longer considered to be occupied by USFW endorsed protocols. However, based on federal and state law, the areas are considered occupied until decertified by WDFW or USFW. As detailed below, extensive surveys indicate that neither northern spotted owls nor northern spotted owl activity centers are present in or around the proposed project area. In addition, the project would not be located within a habitat area designated as critical or identified as essential to owl recovery. Given the extensive survey record confirming the absence of northern spotted owls, the proposed Project would not pose a risk of taking northern spotted owls under the Endangered Species Act Section 9 and its regulations (50 CFR § 17.3).

**Northern Spotted Owl Distribution and Status**

The northern spotted owl is one of three spotted owl subspecies, and the only one found in Washington State. They are distributed from extreme southwestern British Columbia to northern California. In Washington State, they inhabit the Eastern and Western Cascades, Western Lowlands and Olympic Peninsula Provinces. Within these regions, northern spotted owls are associated with a variety of areas containing suitable habitat for nesting, roosting, foraging and dispersal. They prefer forest habitats characterized by multi-layered canopy and a high incidence of large trees that provide suitable structure for nesting and roosting. They have large home ranges and use large tracts of land containing late successional forests. Fragmented forest habitats may be used for dispersal and foraging. They nest in stick nests of northern goshawks, on clumps of mistletoe, in large tree cavities, on broken tops of large trees, or on large branches or cavities in bands and rock faces.

Northern spotted owls are designated as threatened under the Endangered Species Act (16 USC §§ 1531-1544), as well as under Washington State law (WAC 232-12-297). Because they are listed under the Endangered Species Act, USFWS has designated northern spotted owl critical habitat and issued a northern spotted owl recovery plan (USFWS 2008). In addition, the Endangered Species Act prohibits the “take” of northern spotted owls, which includes modifying habitat in a manner that impairs significant behavioral patterns and results in actually killing or injuring an animal (50 CFR § 17.3).

As described in detail below, the Project is not located within habitat designated as critical or identified as essential to northern spotted owl recovery. In addition, the owls prefer forest habitats characterized by multi-layered canopy, and a high incidence of large trees that provide suitable structure for nesting and roosting. No such forests are present within the Project Area. Most importantly, however, extensive surveys following USFWS protocol indicate that the Project is not sited in or near northern spotted owls or spotted owl activity centers. Two historical nesting sites on public lands near the property have not been used in over six and eight years, respectively, and are therefore no longer considered occupied site centers pursuant to USFWS protocol and state law. Based on these facts, this analysis concludes that northern spotted owls would not be “taken” by the proposed Project.
Survey History and Description

The Applicant contracted with Turnstone Environmental Consultants (Turnstone) to conduct wildlife investigations in the proposed Project Area. Surveys were conducted in 2003, 2004, 2008 and 2009, and all surveys followed the Protocol for Surveying Proposed Management Activities that May Impact Northern Spotted Owls (USFWS 1992). In addition, the National Council for Air and Stream Improvement (NCASI) surveyed historical activity centers near the Project Area each year since 1994, the last six years of which were under contract with the DNR. These surveys were conducted in support of an ongoing owl demography monitoring study and, while focused on the same activity centers, placed more emphasis on the nest cores. Table 3.4-3 summarizes the survey results.

Project Area Surveys. Surveys were conducted in suitable habitat located in and adjacent to the proposed Project Area, and included two historical spotted owl activity centers, discussed in further detail below. Suitable habitat was conservatively defined as stands with 12-inch diameter at breast height and greater with a canopy cover of 60 percent or greater. Suitable habitat was identified using topographic maps, aerial photography, and stand classification data from the Applicant. Figure 3.4-6 indicates the location of survey calling stations.

During the 2003–2004 survey periods, the Project Area was surveyed from March–July 2003 using the one-year survey methodology, and from March–August 2004 using the two-year survey methodology. USFWS protocol allows a six-visit survey followed by three-visit survey over two years to rule out northern spotted owls for the following two years (USFWS 1992). No northern spotted owls were detected during the 2003–2004 surveys. See Maps 1 through 5 in Appendix C-5 for 2004 survey locations.

9 Features that support nesting and roosting typically include a moderate to high canopy closure (60 to 90 percent); a multilayered, multi-species canopy with large overstory trees (with diameter at breast height greater than 30 inches); a high incidence of large trees with various deformities (large cavities, broken tops, mistletoe infections, and other evidence of decadence); large snags; large accumulations of fallen trees and other woody debris on the ground; and sufficient open space below the canopy for spotted owls to fly (Thomas et al. 1990.)
More recent northern spotted owl surveys were conducted from May–July 2008 and May–August 2009 (Appendices C-6 and C-7). Surveys were conducted using the USFWS protocol two-year survey methodology, which requires a minimum of three visits for two consecutive years in order to determine presence or absence (USFWS 1992). Surveys were implemented in all potentially suitable habitat located within a 1.8-mile radius of the corridor. This area totaled 14,901 acres. The survey area also included the historical activity centers discussed below, which expanded the survey area by 7,222 acres. No northern spotted owls were detected in either the survey area or historical activity centers in the 2008–2009 surveys.

The Project’s proposed layout was finalized in October 2008 and included additions to proposed turbine strings, removal of previously proposed turbines, and identification of areas requiring improved roadways. Changes to the Project layout resulted in lands added to the Project Area that, in some cases, were not included in wildlife surveys conducted prior to October 2008. The final turbine alignment did expand the area requiring owl surveys; however, because the survey area had included spotted owl activity centers located at the northern reach of the proposed Project Area, the area was accounted for in the 2008 and 2009 surveys.

**Historical Activity Centers.** Two historical northern spotted owl activity centers, Mill Creek (master site no. 0991) and Moss Creek (master site no. 1003), are located near the Project Area (Figure 3.4-6). The nest cores of both activity centers are located on public lands managed by DNR and USFS. The Mill Creek activity center is composed of contiguous but scattered northern spotted owl habitat located on private and DNR lands. This site was designated in 1992, and the last known spotted owls were a non-nesting pair seen in 2000 (Table 3.4-4 and T. Flemming, personal communication.). Since 2000, neither the surveys conducted by the Applicant nor DNR/NCASI have found northern spotted owls.

The Moss Creek activity center is composed of patchily distributed northern spotted owl habitat and a mix of rural residential lands, industrial timberland, and lands administered by DNR and USFS. This activity center was established in 1994 and the last known spotted owl was a male detected in 2002 (Table 3.4-4). Since that time, the Turnstone and DNR surveys have not resulted in any detections.

The longstanding absence of any northern spotted owls at these locations suggests that these historic site centers likely no longer qualify for special protection. As of January 1, 2009, a site center is defined under WAC as the location of status 1, 2 or 3 northern spotted owls, where status 1 means a male and female owl pair (i.e., observed in proximity to each other, a female detected on a nest, or one or both adults observed with young); status 2 means a male and female owl where pair status cannot be determined; and status 3 means either (a) “the presence or response of a single owl within the same general area on three or more occasions within a breeding season” where there is no response by an owl of the opposite sex after a complete survey, or (b) three or more responses over several years (WAC 222-16-010). Only sites documented in substantial compliance with WDFW protocols and quality control methods would be considered site centers (WAC 222-16-010).
Figure 3.4-6

2008-2009 Spotted Owl Calling Points

Whistling Ridge Energy Project
Conditional Use Permit Application
No surveys—whether in substantial compliance with WDFW protocols or otherwise—have documented status 1, 2 or 3 owls on the Mill Creek or Moss Creek sites since January 1, 2009, when the new rule became effective. Furthermore, the Turnstone and DNR/NCASI surveys affirmatively documented the absence of northern spotted owl site centers at these locations. Therefore, the Mill Creek and Moss Creek locations do not meet the definition of a site center under Washington regulations. Even if they did, they should qualify for decertification under the interim decertification rules passed by the Washington Forest Practices Board10.

Similarly, the USFWS protocol allows a historical activity center to be considered unoccupied if no owl responses are obtained after three years of surveys using protocol guidelines (USFWS 1992). These surveys do not need to be consecutive; the protocol anticipates that surveys would be conducted in one- or two-year increments (not three). In any case, however, the DNR/NCASI surveys of the Moss Creek and Mill Creek centers were conducted annually and obtained no responses over six and eight years, respectively. Based on the collective Turnstone and DNR/NCASI surveys, these centers should therefore be considered unoccupied pursuant to the USFWS protocol.

**Barred Owl Concerns.** During the 2003–2004 and 2008–2009 Project Area surveys described above, only barred owls were detected. In addition, the Applicant learned that the USFWS is in the process of revising its protocol for 2010 to include special guidance for conducting surveys where barred owls are detected. After the 2008 surveys, the Applicant consulted with USFWS,

---

10 See Washington State Register 09-02-202 (amending WAC 222-16-080(6)(b) (re-promulgated in Washington State Register (WSRs) 09-10-012 [filed April 24, 2009], 09-18-047 [filed August 27, 2009], 10-10-133 [filed December 21, 2009], and 10-06-026 [filed February 22, 2010]) (emergency rules effective for 2009 calendar year and until June 17, 2010 when a permanent rule became effective [WSR 10-11-081, filed May 17, 2010] establishing “spotted owl conservation advisory group” to determine whether northern spotted owl site center need be maintained based on surveys demonstrating absence of the owls).
and was instructed to follow existing survey protocol (K. Berg, personal communication). The Applicant did so, but also incorporated USFWS’s suggestion that biologists visit core areas during the day to look for northern spotted owls, which might not respond in the presence of barred owls. Biologists conducted three day-time site visits over the seasonal breeding window in 2009 but did not detect any northern spotted owls.

**NSO Habitat Designations**

Federal and state habitat designations can be useful in characterizing the importance of certain areas to spotted owl life cycles and recovery. In this case, as described in the subsections below, the Project would not be located in the areas designated as most critical to northern spotted owls or identified as essential to their recovery. The Project would be located within a state-delineated management area, but the absence of a site center means that management restrictions would not be applicable to the Project Area.

**Managed Owl Conservation Area and Designated Critical Habitat Area.** The USFWS released its Final Recovery Plan for the Northern Spotted Owl in 2008 (USFWS 2008), which recommends a network of habitat blocks, or managed owl conservation areas (MOCAs), on federal lands in the west-side provinces in the northern spotted owl range. MOCAs were designated to correspond to the owl’s full geographic distribution. The recovery plan’s strategy focuses on managing MOCAs to support self-sustaining populations of 15 to 20 spotted owl pairs, as well as spacing and managing areas between MOCAs to permit owl movement between and among MOCAs (USFWS 2008). The revised critical habitat designation, also issued in 2008, concluded that the MOCA network is “sufficient to achieve the recovery” of northern spotted owls and designated only those lands as critical (73 Federal Register page 47,328). The Project Area is not located within, adjacent to, or between federally designated MOCAs or, therefore, corresponding designated northern spotted owl critical habitat (Figure 3.4-7).

**Conservation Support Area.** In the final recovery plan, USFWS delineated Conservation Support Areas (CSAs) to support designated MOCAs. CSAs are areas between or adjacent to MOCAs where habitat contributions made by private, state or federal land managers “are expected to increase the likelihood that [spotted owl] recovery is achieved, shorten the time needed to achieve recovery, and/or reduce management risks…” (USFWS 2008). In Washington State alone, the USFWS delineated 2,163,453 acres as CSA habitat.

The proposed Project Area is located within the Klickitat CSA, a 425,114-acre mix of private, state and federal lands (Figure 3.4-7). The Project Area’s location within a CSA does not mean that spotted owls are present in the Project Area, or that modification of the area would compromise owl recovery. As the USFWS explained in excluding CSAs from designated critical habitat, “although recognized as potentially helpful in achieving recovery plan goals, these areas were not considered essential to the conservation of the species” (73 Federal Register page 47,331). Although CSAs are not unimportant, the recovery criteria for northern spotted owl populations “do not require the contributions of [CSAs] as an essential component of recovery” (USFWS 2008). Moreover, to the extent CSA lands provide an important function in supporting the MOCA network, it is worth noting that the Project Area constitutes just 0.27 percent of Klickitat CSA lands and 0.053 percent of Washington CSA lands.
**Spotted Owl Special Emphasis Area.** In 1996, Washington State finalized a rule identifying ten spotted owl special emphasis areas (SOSEAs) to complement protections provided by the Northwest Forest Plan. The proposed Project is located in the southernmost portion of the White Salmon SOSEA which, like the Klickitat CSA, was delineated with the goal of providing demographic support (WAC 222-16-086[10]). In such areas, any suitable spotted owl habitat should be maintained (WAC 222-10-041[1]). More specifically, all suitable habitat within 0.7 mile of a site center plus 2,605 acres (approximately 40 percent) of suitable habitat within the median home range circle (a 1.8 mile radius) is assumed necessary to maintain the site center’s viability (WAC 222.10.041[4]). This 40 percent suitable habitat level corresponds with USFWS research on the level of habitat necessary to avoid take and support recovery. According to DNR, both the Mill Creek and Moss Creek site centers exceed 40 percent of the suitable habitat. The proposed Project would not alter that fact. Therefore, the SOSEA limitations on habitat use or modifications do not restrict use of the Project Area as a wind turbine energy facility. Forest practices within a SOSEA are therefore allowed to proceed so long as they do not affect the 40 percent suitable habitat threshold.

**Habitat Conservation Plans.** A review of USFWS habitat conservation plans issued in the Pacific region indicates that there is one spotted owl-related habitat conservation plan (HCP) applicable in or near the Project Area (USFWS 2009b). The HCP covers DNR managed land directly to the north of the Project site, but not the Project site itself. The Applicant has sited the proposed Project to avoid habitat areas deemed critical to northern spotted owls or essential to their recovery. Surveys conducted pursuant to USFWS protocol indicate that spotted owls are not present in or near the Project, and that nearby historical sites are no longer occupied pursuant to USFWS protocol or state law. Because there are no spotted owls or activity centers present in the Project Area, no Project impacts to northern spotted owls are expected. Finally, the Project would not affect the White Salmon SOSEA’s 40 percent suitable habitat level and therefore is not restricted by Washington’s forest practice regulations. Given the extensive record and review, this Project does not pose a risk of taking northern spotted owls under The Endangered Species Act Section 9.

**Olive-Sided Flycatcher**

The Olive-Sided Flycatcher is not listed as federally or state threatened or endangered, however, it is considered a federal species of concern. The Project habitat is not very conducive for this species, and that is why only a few individuals were observed. The species does migrate and it would not be expected in the Project Area in winter or early spring. This species occurs in forest habitat and adjacent cleared areas such as burned areas or clear cuts. They perch high in treetops and catches insect prey on the wing in cleared areas. They breed in Washington State and also

---

12 Data provided by DNR which shows Mill Creek at 48 percent and Moss Creek at 55 percent (J. Herman, personal communication)
migrate through during August to areas in South America. The olive-sided flycatcher is considered a fairly common breeder in the area encompassed by the Project Area (BirdWeb 2009). There were 21 birds observed during summer 2006 avian surveys, and six recorded during the spring of 2009. All 21 observed in 2006 were within the rotor-swept area; it is not reported in 2009 how many were in the rotor-swept area. None were recorded during the fall of 2004 or the winter of 2008–2009 (Appendix C-4).

**Pileated Woodpecker**

The pileated woodpecker is considered a Washington State Candidate for listing. This species occurs in all forest types as long as large trees exist for nesting and foraging. Old-growth and mature forest therefore are a common association. In Washington, pileated woodpeckers occur year round but are uncommon in the vicinity of the Project Area. They are more common west of the Cascades. During avian surveys in the Project Area, six pileated woodpeckers were recorded in the fall, two during the winter, seven during the spring, and none in the summer. None occurred within the rotor-swept area (Appendix C-4).

**Vaux’s Swift**

Vaux’s swift is considered a Washington State Candidate for listing. It typically occurs in coniferous or mixed forest of mature age where snags are available for roosting and nesting. They forage for insects in flight in open sky, typically above woodlands or bodies of water. In Washington, Vaux’s swift breeds widely, and the Project Area is considered within the range of common occurrence for the species. They migrate south during the fall. During fall 2004 avian surveys, 15 Vaux’s swifts were recorded in three groups, 87 percent of which occurred within the rotor-swept area. Four were recorded in two groups during the summer of 2006, all of which occurred within the rotor-swept area. Eleven were recorded during the summer of 2009; the number within the rotor-swept area was not reported in this study (Appendix C-4).

**Western Gray Squirrel**

The western gray squirrel is listed as a “threatened” species by WDFW. In Washington, western gray squirrel distribution has been reduced to three geographically isolated populations: the “Puget Trough” population, centered in Thurston and Pierce counties, the “South Cascades” population, located in eastern Skamania County, Klickitat and Yakima Counties, and the “North Cascades” population, located in Chelan and Okanogan Counties. Western gray squirrels are arboreal species. Although they forage on the ground, this species rarely strays far from trees. They use tree canopies for cover and nesting. Western gray squirrels prefer areas where contiguous tree canopy allows arboreal travel in a minimum of a 198 feet (60 meters) radius around the nest (Ryan and Carey 1995). Western gray squirrels are diurnal species, with most activity occurring during morning hours. This species is most active during August and September, when this species is collecting and storing food for winter (Ryan and Carey 1995). The principal food source for the gray squirrel is acorns; however, conifer seeds are also eaten (Dalquest 1948). While pine nuts and acorns are considered essential foods for accumulating body fat in preparation for winter, green vegetation, seeds, nuts, fleshy fruits, and mushrooms also are consumed (WDW 1993, Carraway and Verts 1994, Ryan and Carey 1995).
Figure 3.4-7
Map of Spotted Owl MOCAs and CSAs

Whistling Ridge Energy Project
Skamania County, Washington
Western gray squirrel surveys were implemented by the Applicant on lands located in and adjacent to the Project Area in 2004, 2008, and 2009 (Figure 3.4-8). Surveys conducted in 2004 included a general search for western gray squirrels and nests while conducting northern goshawk station placement and surveys. Two adult western gray squirrels were identified during that effort.

An additional protocol survey was completed following methods described in Surveys for western gray squirrel nests on sites harvested under approved forest practice guidelines: analysis of nest use and operator compliance (Van der Haegen et al. 2004). No western gray squirrels were detected during protocol surveys. Detailed methodology and results for western gray squirrel surveys in 2004 can be found in Appendix C-5.

Additional western gray squirrel surveys were completed by the Applicant in 2008 and 2009. Prior to implementing field surveys, the Applicant consulted with a WDFW biologist to identify survey criteria and methodology. It was determined that gray squirrels surveys should be performed in areas where Project activities would result in the removal of potential western gray squirrel habitat or structural modification (i.e., stand thinning), and these surveys should include unaltered habitat within 400 feet of potential disturbance.

An area consisting of a 1,050-foot buffer around the proposed turbine layout to account for lands that may be affected by the Project, and also the 400-foot buffer of undisturbed lands, was identified for potential survey. This area included 1,420 acres; however, only 738 acres were identified as potentially suitable to support western gray squirrel (Figure 3.4-8). Surveys were conducted following methods described by Van der Haegen, Van Leuven, and Anderson (2004). Surveyors searched for individuals and nests, focusing mainly on gray squirrels, but also noting other species. When possible, historical use by western gray squirrels was determined. No gray squirrels or nests were detected during these surveys in 2008 or 2009. Detailed methodology and results can be found in Appendices C-6 and C-7.

**Keen’s Myotis**

Keen’s bat is considered a Washington State Candidate for listing. In Washington, this species is recorded as occurring on the Olympic Peninsula and Cascade Mountains (BCI 2009). The Project Area is likely on the very edge of the distribution range for Keen’s myotis. Although little is known about this species, it is believed to rely on old-growth forests. Keen’s myotis likely roosts in tree cavities and forages in dense coniferous forests. Bat surveys conducted during 2007, 2008, and 2009 (Appendices C-8, C-9, and C-10) did not have the ability to detect individual species of bats. Instead, bats are grouped into species with either “high-frequency” calls or “low-frequency” calls. Keen’s myotis is considered part of the “high-frequency” group. Based on the lack of detailed information of this species life history and habitat requirements and nature of the bat surveys conducted it is difficult to conclude with certainty what the likelihood of Keen’s bats occurring in the in the Project Area. However, due to the lack of old-growth or mature forest types within the Project area and the predominant commercial forestry use of the property, the likelihood of occurrence on the site is considered to be low.
Townsend’s Big-Eared Bat

Townsend’s big-eared bat is a federal species of concern and a Washington state candidate for listing. Its distribution spans the western US, and occurs primarily in desert scrub and pine forest regions (BCI 2009). In the spring and summer, females form maternity colonies in mines, caves or buildings. In winter they hibernate in caves and abandoned mines. These maternity and roosting locations are sensitive to disturbance. It forages after dark in upland areas. Bat surveys conducted in the Project Area during 2007, 2008, and 2009 (Appendices C-8, C-9, and C-10) did not have the ability to detect individual species of bats. Instead, bats are grouped into species with either “high-frequency” calls or “low-frequency” calls. Townsend’s big-eared bat is considered part of the “low-frequency” group. Based on lack of detailed information on this species distribution and the nature of the bat surveys conducted on the site, it is difficult to conclude with certainty the likelihood of Townsend’s big-eared bats occurring in the Project Area. There are no known roosting structures or maternity colonies occurring in the vicinity of the Project Area. Consequently, the likelihood of occurrence on the site is considered to be low.

3.4.1.6 Other Wildlife Species

In addition to studies of special status species, other studies of birds and bats at the Project site have been ongoing since 2004. Birds were surveyed during all seasons of the year in the fall of 2004, summer of 2006, winter 2008–2009 and spring of 2009. Results are summarized in Appendix C-4.

Bats were surveyed during the fall of 2007, summer–fall of 2008 and summer–fall of 2009. Results of those studies are presented in Appendices C-8, C-9 and C-10. The timing of these surveys is expected to capture the peak of bat use during the breeding season (summer) and migration (fall). Information on the potential for other taxonomic groups to occur in the Project Area is based on general distribution and habitat requirements for individual species.

Birds

Avian surveys were conducted in the Project Area across all seasons in multiple years. There were: 53 surveys during the fall migration period (September 11 to November 4, 2004), 45 surveys during the breeding/nesting season (May 15 to July 14, 2006), 47 surveys during winter and 116 surveys during spring (December 4, 2008 to May 29, 2009).13

Study protocol followed methods described by Reynolds et al. (1980). An 800-meter circular plot was centered on each observation point (Figure 3.4-9). All observations, behavior, and flight patterns of birds in and near plots were recorded. Flight patterns, such as direction of travel and flight altitude also were recorded.

---

13 In its 2003 Energy Overlay Environmental Impact Statement, Klickitat County also included two survey locations at or in proximity to the Project site. These included surveys during the spring and summer 2003 seasons. See Appendix B to the Klickitat County Energy Overlay Draft Environmental Impact Statement (Kennedy/Jenks Consultants 2003).
Western Gray Squirrel Survey Areas

Site Boundary

Figure 3.4-8
Western Gray Squirrel Survey Areas

Whistling Ridge Energy Project
Conditional Use Permit Application
Observations of birds beyond the 800-meter radius were recorded; however, these data were analyzed separately from data collected from survey plots. The location of raptors, other large birds, or species of concern observed during counts was recorded on field map. A list of all birds recorded in the Project Area (including those during special status species surveys) is provided in Table 3.4-5. Appendix C-4 contains full results of fall 2004, summer 2006, winter 2008-09 and summer 2009 surveys.

A total of 87 species were recorded during avian surveys. Passerines (songbirds) were the most abundant avian group overall. American robin, dark-eyed junco and white-crowned sparrow were the three most frequently observed birds across all seasons. Mean overall bird use in the study area was low compared to these other wind resource areas studied; ranking 19th compared to 24 other wind resource areas (Figure 9 in Appendix C-4). Eleven species of raptors were observed: American kestrel, bald eagle, Cooper’s hawk, golden eagle, northern harrier, northern goshawk, osprey, prairie falcon, red-tailed hawk, sharp-shinned hawk, and turkey vulture. Red-tailed hawk was by far the most observed raptor, followed by Cooper’s hawk and sharp-shinned hawk. Mean annual raptor use was 0.28 raptors per plot per 20-minute survey, which is a standardized way to measure use in order to compare results to avian use at other sites. This annual rate is low relative to raptor use at 36 other wind-energy facilities that implemented similar protocols and had three or four season surveys. Mean raptor use in the study area was low compared to these other wind resource areas; ranking 29th compared to 36 other wind energy facilities (Figure 7 in Appendix C-4).

**Fall Migration Surveys (2004)**

General avian surveys identified 39 species of bird in the survey area (Figure 3.4-9). Passerines (songbirds) were the most abundant avian group, constituting 87.4 percent of observations. This group was observed with the greatest frequency (94.4 percent of surveys). Raptors were the second most abundant group observed; however, this group represented only 4.9 percent of observations. Raptors were observed during 38.5 percent of the surveys, followed by woodpeckers (22.6 percent of surveys) and doves/pigeons (9.3 percent of surveys).

The most common species at the Project Area included dark-eyed junco, American goldfinch, Steller’s jay, common raven, and white-crowned sparrow. The species of birds most frequently observed during fall surveys were common raven, Steller’s jay, dark-eyed junco, red-breasted nuthatch, and golden-crowned kinglet. Eight species of raptor were observed during the survey. Those with the highest use of the site were sharp-shinned hawk, Cooper’s hawk, and red-tailed hawk. The highest raptor use observed at the site during 2004 surveys occurred between September 11 and October 12, 2004. These data do not indicate that any areas within the proposed site have substantially higher raptor use than others.

No federal or state listed endangered or threatened avian species were observed during the survey period. Four state candidate species were observed: golden eagle, northern goshawk, pileated woodpecker, and Vaux’s swift. Two State Monitor species were observed, including four single turkey vultures and four groups totaling 27 western bluebirds. Detailed results and summary tables can be found in Appendix C-4.

</table>
Summer Surveys (2006)

Fifty-five species of birds were observed during summer breeding and nesting surveys in 2006 (Figure 3.4-9). Passerines were the most abundant group (88.5 percent), followed by raptors and woodpeckers (3.3 percent each), and doves/pigeons (3.2 percent). The most frequently observed groups were passerines (100 percent of surveys), woodpeckers (35.6 percent of surveys), and raptors (31.1 percent of surveys). Species with the highest use of the Project Area included white-crowned sparrow, red crossbill, western tanager, spotted towhee, and MacGillivray’s warbler. The most frequently observed species included white-crowned sparrow (77.8 percent of the surveys), western tanager (75.6 percent of surveys), spotted towhee (64.4 percent of surveys), MacGillivray’s warbler (48.9 percent), and dark-eyed junco (48.9 percent). Three species of raptors were observed, including red-tailed hawk, northern goshawk, and sharp-shinned hawk. Raptor use in the fall was only slightly higher than during the summer breeding season. The data do not indicate that any portions of the Project Area have substantially higher raptor use than other areas. For all bird species combined, use of the Project Area by avian species was slightly higher during the summer breeding season than during the fall migration period. Detailed results and summary tables can be found in Appendix C-4.

Winter/Spring Surveys (2008-2009)

Fifteen species of birds were observed during winter surveys in 2008–2009, and 65 species during the spring of 2009. In winter, observations were dominated by common raven, American robin, and unidentified finches. The number of species and number of individuals observed in the spring were the highest across all seasons. Similar to other seasons, passerines were the most abundant group, followed by woodpeckers and then raptors. Individual species with the highest use included American robin, dark-eyed junco and yellow-rumped warbler. The data do not indicate that any portions of the Project Area have substantially higher raptor use than other areas. Detailed results and summary tables can be found in Appendix C-4.

The WDFW Priority Habitats and Species database was searched for known occurrences of raptor nests. The only recorded nest was for an osprey, more than one mile east of the Project Area.

Bats

Bat acoustic studies were conducted for the Project in 2007, 2008 and 2009. Detailed information on these investigations can be found in Appendices C-8 (2007), C-9 (2008) and C-10 (2009).

Bat acoustic studies conducted from 2007 through 2009 were implemented at various locations in the Project Area. The goal of the studies were to: (1) characterize the local bat population in a variety of habitats, (2) identify areas of high usage by bats, and (3) characterize the frequency of bat usage of areas representative of where turbine strings would be located. Studies were done across several seasons to estimate annual variation during breeding and periods of migration.

For all studies, passive Anabat® II echolocation detectors coupled with Zero Crossing Analysis Interface Modules (ZCAIM; Titly Electronics Pty Ltd., NSW, Australia) were used in all survey years. Anabat detectors record bat echolocation calls using a broadband microphone. Bat species are generally grouped into those that emit low frequency (<35 kHz) or high frequency (≥
35 kHz) calls. The units of activity equaled the number of bat passes, and were used to calculate the number of bat passes per detector night (Hayes 1997). The data thus indicate the level of bat activity rather than absolute abundance.

In 2007, detectors were placed at two locations from August 20 through October 21 (Figure 1 in Appendix C-8). The 2007 studies were intended to provide a general census of bat activity in recently reforested or young forest areas. This type of habitat is similar to what would be found in the areas within 150 feet of the proposed turbines, on the two sides of the turbines. The northernmost detector was located just outside the proposed turbine corridor. This detector was initially placed at ground level; however, it was raised to a height of 130 feet (40 meters) on September 7. The southernmost detector was located outside the Project Area; however, it was placed in habitat believed to be representative of that found in the Project Area. The southernmost detector was placed at ground level, and remained at that location for the duration of the study.

Due to equipment failures in 2007, both Anabat detectors were only operable for 24 percent of the sampling period, amounting to 45 detector-nights. Bat activity was similar between north and south ground level Anabat units (mean = 11.67 ± 2.0 and 9.6 ± 4.1, respectively). Bat activity recorded after the northern Anabat detector was elevated was much lower (mean = 2.47 ± 1.1) than that recorded at ground level. A list of bat species with potential to occur in the Project Area based on range maps, divided between high-frequency and low-frequency species, can be found in Table 3.4-6.

Status Codes:
FCo – Federal Species of Concern
SC – State Candidate
SM – State Monitor

(no information on call frequency was provided for Western pipistrelle)

The bat acoustic survey effort was increased to four locations during the 2008 survey period, and the survey period covered July 3 to October 7, 2008. This period corresponded with summer
breeding and fall bat migration. Four survey locations were used, all on the ground (Figure 1 in Appendix C-9). Two were located in clear cuts (SB1 and SB4), one immediately adjacent to a wetland (SB2) and one in a road corridor (SB3). Sampling at the wetland was intended to characterize bat occurrence a location known to have a high level of usage, because wetlands are frequently used as foraging and drinking habitat for bats. Similarly, sampling in the road corridor was intended to capture the highest levels of use within the Project Area, because road corridors are frequently used by bats to travel between roosting and foraging locations. The two clear cut sites were most representative of the types of habitat where turbines would be located for the proposed Project. However, because all detectors were located on the ground, sampling did not entirely capture the potential bat use of the rotor-swept area.

Table 3.4-7 summarizes bat activity at all survey locations. During the 2007 and 2008 surveys, the two clear cut sites (SB1 and SB4) had an average of 14.30 and 73.76 bat passes per night, respectively. The wetland (SB2) and road corridor (SB3), recorded much higher levels of use, at 178.03 and 327.25 bat passes per night, respectively. Seasonal activity patterns were similar for the two clear cut survey locations, with the highest bat activity occurring during the months of July and August. Bat activity in the wetland area was highest during the month of July. In comparison to 2007, bat numbers were on average higher because in 2007 this peak use period was not captured during the sampling period (in 2007 sampling did not begin until August 20).

In 2009, the bat survey efforts were further refined to focus specifically on the types of locations where turbines would be sited. Three locations were selected (Figure 3.4-10), two in clear cuts and one in a recently reforested area (young forest). In addition, each sampling location had a pair of Anabat detectors; one on the ground and one elevated on a meteorological tower. The elevated detectors were intended capture bat use in what would likely be the rotor-swept area, which is where potential bat-turbine collisions would occur. The ground level detectors were intended to provide some comparison to prior year studies, most of which were done at ground level. The numbers of bat detections in 2009 are summarized in Table 3.4-7.
In general, elevated detectors recorded fewer bats than their ground level counterparts, indicating that bat occurrence within the rotor-swept area is lower than those at lower flight elevations. For all years (2007–2009), elevated bat detections were the lowest numbers recorded, between 1.53 and 10.50 bat passes per night. All bat detections in 2009 were collected by Anabat equipment installed in locations most representative of potential turbine locations. The detections were notably lower than some of the other records in 2008 taken from equipment placed in areas of known high bat use.

**Amphibians and Reptiles**

Amphibians and reptiles likely to occur within the Project Area are those species that can tolerate disturbance associated with managed timber activities and drier-than-average conditions for at least part of their life cycle. This includes such common species as Long-toed salamander (*Ambystoma macrodactylum*), Rough-skinned newt (*Taricha granulose*), Ensatina (*Ensatina eschscholtzii*), Pacific treefrog (*Pseudacris (=Hyla) regilla*), and northwestern garter snake (*Thamnophis ordinoides*). Breeding may occur within the intermittent drainages located in the northeast corner of the site, within cedar swamp, or substantial roadside drainage ditches. These species may stray further from water sources during heavy rains or during winter conditions.

**Mammals**

Several large mammals have the potential to occur within the Project Area. Known priority wildlife habitats, including mule deer and black-tailed deer (*Odocoileus hemionus*) winter range, are present east of Underwood Mountain, extending to lands to the north/northeast. Winter range for Columbia black-tailed deer is present in lands west of Underwood Mountain, and extends north and south from the Project Area. Elk (*Cervus elaphus*) winter range is present throughout the Project Area. Other species likely to occur throughout the region include cougar (*Puma concolor*), bobcat (*Lynx rufus*), coyote (*Canis latrans*), and black bear (*Ursus americanus*). Douglas squirrels (*Tamiasciurus douglasii*) were recorded during surveys for the western gray squirrel.

**Fish**

No fish have been documented within the Project Area. The Project is on a ridgeline between Underwood Mountain and the White Salmon River, approximately 3 miles north of the Columbia River. The ridgeline is oriented in a north-south direction. The Columbia River receives runoff via the White Salmon drainage area east of the site and via the Little White Salmon River west of the site. The White Salmon River contains evolutionarily significant units and designated critical habitat for three species listed as threatened under the Endangered Species Act: (1) Lower Columbia River Chinook, (2) Middle Columbia River Steelhead, and (3) Columbia River Chum (Figure 3.4-11).

A tributary to Little Buck Creek is located in the northeast portion of the Project Area. This tributary is typed as a non-fish-bearing stream. No special status fish species are present in Little Buck Creek. However, Buck Creeks drains into Northwestern Lake, which in turn drains into the White Salmon River.

West Pit Road crosses an unnamed drainage. This stream had observed flow through the existing culvert under West Pit Road at the time of the July 2009 field visit. However, the surface flow and the channel disappear downstream of the culvert. There is no surface water connection to Lapham Creek or the Little White Salmon River. Fish are not present in this stream.

### 3.4.1.7 Noxious Weeds

The Project Area contains several noxious weed species, which are nonnative, invasive plants. The weed species observed during field visits to date are listed in Table 3.4-8.

The Washington Noxious Weed Control Board identifies lists of noxious weed species that require control, eradication, or monitoring. Class A noxious weeds are nonnative species with a limited distribution within a state and require eradication to reduce the potential of becoming more widespread.

Class B noxious weeds are regionally abundant, but may have limited distribution in some counties. In Washington, in regions where a Class B noxious weed is unrecorded or of limited distribution, prevention of seed production is required. In these areas the weed is a “Class B designate.” However, in regions where a Class B species is already abundant or widespread, control is a local option. In these areas the weed is a “Class B non-designate.”

Class C noxious weeds are already widely established, but placement on the state list allows counties to enforce local control if desired. Skamania County has designated a few Class C weeds. Within the Project boundary, only Canada thistle (*Cirsium arvense*) is a designated Class C weed.
3.4.2 IMPACTS

This section identifies the potential impacts to biological resources as the result of both construction and operation of the proposed Project.

3.4.2.1 Proposed Action

Skamania County Critical Areas Ordinance Regulation

The Skamania County Critical Areas Ordinance recognizes the following as critical areas: watershed protection areas (including wetlands, streams, creeks, rivers, ponds and lakes); critical aquifer recharge areas; fish and wildlife habitat; frequently flooded areas; and geologically hazardous areas (including landslide hazards, erosion hazards and volcanic hazards). All critical areas have a required no-touch buffer setback based on the classification of the critical area, as set forth in Skamania County Critical Areas Ordinance Title 21A. All buffers are undisturbed buffers and must be free of any logging, road building, or other development activities including, but not limited to, vegetation removal, grading, filling, mowing, or placement of structures. The Project would not affect any critical areas or buffers.

Construction

Habitat Types

Construction and operation of the Project would require the removal of vegetation in some areas to accommodate roadway construction and improvement, turbine siting, staging, and construction. The impacts of Project construction would not differ substantially from customary forestry activities on the site. Each turbine footing and foundation would measure approximately 3,100 square feet. Vegetation surrounding each turbine would be managed according to the following specifications:

- A circular area extending 50 feet from each turbine tower base would be harvested and graveled;
- From 50 feet to 150 feet from the base of the turbine towers, tree heights would be limited to 15 feet above the elevation of the base of the turbine; and
- From 150 feet to 500 feet from the base of the turbine towers, tree height would be limited to 50 feet above the turbine base within an area formed by a 90 degree arc centered on the ordinary downwind direction (Figure 2-4 in Chapter 2).

The A and F turbine strings and parts of the B and C turbine strings would be accessed by existing roads. Modifications to these roads are anticipated in order to support the long and heavy loads required for delivery of the wind turbine systems. An estimated 5.1 miles of roads within the Project Area would require improvements as a result of the proposed Project. The majority of new roads would be constructed to access parts of the B and C turbine strings, and all of the D and E turbine strings. Access to these turbines would require 2.4 miles of new roadway. All roads used to access turbines would be maintained throughout the life of the Project.
All vegetation clearing would be completed using crawler tractors, rubber-tired skidders, mobile feller-bunchers, or cable yarding equipment. This equipment is typically used in timber harvest, and is currently used to harvest other stands located on the Applicant’s property. Logs would be transported by truck to Applicant facilities in Bingen, Washington. Except for permanently cleared areas, cleared areas would be replanted with trees within one year following completion of construction (typically the following spring). Areas where trees are permanently removed would be replanted with appropriate native grasses and low-growing shrubs. Because trees would be cleared for the purpose of the Project, cleared areas would be considered “forest conversion” under the Washington Forest Practices Act. However, cleared areas would still be reforested in accordance with typical commercial forestry management practices when feasible. Permanent and temporary impacts to habitat types within the Project Area can be found in Tables 3.4-9 and 3.4-10.

West Pit Road was widened in the summer of 2009. Additional road improvements would be required during the construction phase of the Project. However, the loss and modifications of habitat types from these modifications are anticipated to be minor. Tables 3.4-9 and 3.4-10 show the temporary and permanent impacts of the Project to the habitat types found on the site and along the portion of West Pit Road that would be improved.

*a* Total permanent impact area of proposed development within the 650-foot corridor measured on either side of an imaginary line connecting each turbine string.

*b* The permanent impact area of proposed roadway modifications within the Project Area encompassed by a 100-foot corridor along all roads. Does not include overlap of transmission corridor or turbine corridor. Also excludes existing roadway.

*c* The permanent impact area of proposed development within the area encompassed by a 100-foot corridor along all Project transmission lines. Does not include overlap of road corridor or turbine corridor.

*d* The permanent impact area is based on the assumption that the existing roadway is 20 feet wide, the new roadway would be 25 feet wide, and that an additional 5 feet on each side of the roadway would be permanently cleared.

**Wetlands**

No wetlands or wetland buffers are located within the Project footprint. Therefore, no wetlands or buffers are expected to be affected by construction of the Project.

A review of the National Wetland Inventory indicates that wetlands may occur along SR 14 but not along County or private roads proposed for the Project’s construction access and turbine delivery routes. No improvements to SR 14 are anticipated to be required, and therefore no wetland-related impacts would occur. Roadway improvements to the County or private logging roads are not expected to affect wetlands. This information was confirmed through field investigations performed in May and July 2009.

See Section 3.3 for a discussion of impacts to other surface water features such as streams.

**Special Status Plant Species**

No federal- or Washington State-listed plant species have been documented at the site during multiple field surveys. Therefore, no project-related impacts are anticipated from construction of the proposed Project. Two plant species on the WNHP Watch List, gnome plant and phantom orchid, were observed within areas that may be cleared for construction of the Project. Both species are growing in areas that have been previously clearcut and were able to re-establish. In addition, there are no regulatory requirements to protect these species.
Special Status Wildlife Species

Potential construction related impacts to bald eagle, golden eagle, northern goshawk, northern spotted owl, olive-sided flycatcher, pileated woodpecker, Vaux’s swift, western gray squirrel, Keen’s myotis, and Townsend’s big-eared bat are discussed in this section.

**Bald Eagle.** Four bald eagles were recorded in the Project Area. The Project Area is over two miles away from the nearest known bald eagle foraging habitat, which is the Columbia or White Salmon Rivers. Therefore bald eagle use of the Project Area is considered infrequent and sporadic. The removal of coniferous forest as a result of Project construction that far away from suitable foraging habitat would not impact bald eagles. No breeding habitat would be affected.

**Golden Eagle.** Golden eagles have been recorded in the Project Area; however they are considered an uncommon visitor to this region of Washington State. They are known to forage in mid-elevation clear cut habitat. The permanent removal of 21.31 acres of grass-forb stand or shrub habitat for construction of turbine strings and transmission line corridors would decrease the amount of foraging habitat available to golden eagles within the Project Area. Any golden eagles potentially using the Project Area for foraging would likely be temporarily deterred from using the site by construction vehicle and personnel activity.

**Northern Goshawk.** Northern goshawks were recorded in the Project Area. Although they were recorded during the summer, no evidence of nest or breeding individuals was observed during multiple years of surveys. A breeding goshawk may have a wide area of home range spanning multiple age classes of forest. They also may forage in open areas. Construction of the proposed Project would result in the permanent loss of 21.86 acres of managed coniferous or mixed deciduous-coniferous forest. This would represent a loss of habitat generally suitable for goshawks, though unlikely to support breeding pairs. Goshawks also forage in open area, where they swoop to the ground to capture prey. Approximately 17.13 acres of grass-forb habitat would be permanently lost during construction of the Project.

**Northern Spotted Owl.** The Applicant has sited its proposed Project to avoid habitat areas deemed critical to the northern spotted owl or essential to its recovery. Surveys conducted pursuant to the USFWS protocol indicate that spotted owls are not present in or near the Project, and that nearby historical sites are no longer occupied pursuant to USFWS Protocol and state law. Because there are no northern spotted owls or activity centers present in the Project area, no Project construction impacts are expected. Finally, the Project would not impact the White Salmon SOSEA’s 40 percent suitable habitat level and therefore is not restricted by Washington’s forest practice regulations. Given the extensive record and review, this Project does not pose a risk of taking northern spotted owls under Endangered Species Act Section 9.

**Olive-sided Flycatcher, Pileated Woodpecker, and Vaux’s Swift.** These three avian species are all passerines with known occurrence within the Project Area. All three use coniferous forest for nesting. Construction of the proposed Project would result in loss of 21.86 acres of forest habitat. Construction during the breeding season would likely result in disturbance of any individuals occurring in the vicinity, thereby temporarily reducing the use of further areas of habitat. Vaux’s swift and olive-sided flycatchers forage on the wing over cleared areas, so it is likely that no additional habitat loss would occur for these species as the result of conversion of forested area to clearing (grass-forb stand).
**Western Gray Squirrel.** The construction of the proposed Project would result in the permanent removal of 21.86 acres of managed coniferous or mixed deciduous-coniferous forest. The gray squirrel prefers habitat where contiguous tree canopy allows arboreal travel in a minimum of a 198-foot (60-meter) radius around the nest (Ryan and Carey 1995). Current forest management practices on forest within the proposed Project Area has created habitat not generally suitable for this species, due to fragmentation of mature forest stands. Contiguous forest habitat located in the Project Area would not develop in the future. The Project Area also contains very few oak trees, and those that were observed were of small stature (less than 20 feet tall), stunted, and growing in openings on exposed rocky slopes in shallow soils. Acorn crops from oak trees are an important food source for western gray squirrels, and the lack of this primary food source may deter use of the Project Area by gray squirrels. Because habitat for this species is considered rare or of moderate/poor quality in the Project Area, impacts to western gray squirrel due to loss of coniferous forest habitat are expected to be negligible.

**Keen’s Myotis and Townsend’s Big-Eared Bat.** The special status bat species may occur in the Project Area, based on their documented distribution. Surveys for bats were not able to identify all bats to species level. Both species may utilize mature or old-growth forested habitats within the Project Area, if suitable nest sites were available. Permanent loss of 21.86 acres of forest habitat and 21.31 acres of shrub/grass/forb habitat may result in a small reduction of suitable habitat for these species. No known roosting or breeding locations would be impacted.

**Other Wildlife Species**

In general, wildlife in the Project Area could be affected by the construction of the Project through the loss of suitable habitat, potential fatalities during clearing or grading of the construction area, and disturbance/displacement from construction activity and personnel occupying the site. Fragmentation of the remaining habitat also could occur, although current land management practices result in an existing source of ongoing fragmentation on the site. Therefore, permanent vegetation removal and temporary construction disturbance are the primary impacts as a result of the proposed Project.

**Birds.** Direct mortality to birds and/or bird nests could occur during the initial clearing or grading of the construction areas. Additional disturbance could occur indirectly to birds or bird nests occurring adjacent to construction areas. This may occur if a nest or a primary foraging area is nearby. In areas where temporary disturbance would occur, it is anticipated that birds would generally reoccupy restored habitats with time. Some habitat would be permanently converted from one type (forest) to another (clear cut or grass-forb). This would result in a temporary disturbance, likely followed by recolonization of the area by a different suite of birds.

**Bats.** Impact to bats as a result of construction would be minimal unless known nesting or roosting sites were removed. Disturbance or displacements to bats as a result of construction activities would be minimal because bats are primarily active during the night, when construction would not occur.

**Amphibians/Reptiles.** No wetlands or other surface water bodies are proposed to be filled as a result of the Project. Therefore, no amphibian breeding habitat would be directly impacted. Amphibians and reptiles would potentially experience direct loss of non-breeding habitat and further fragmentation of the remaining habitats.
Mammals. No direct mortality of large mammals is anticipated as a result of construction because these species are able to relocate away from heavy equipment used in clearing and grading. Some avoidance of the area due to disturbance would likely occur on a temporary basis. Permanent removal of vegetation would result in the loss of some habitat for these species. The conversion of one habitat type to another would likely not reduce the amount of area available to the more commonly-occurring species, which utilize multiple habitat types during their life cycle.

Fish. No impacts are anticipated from construction of the Project. No perennial streams or fish are located within the construction areas within the Project boundaries. In addition, the construction would occur when the ephemeral drainages that cross the access roads are dry. This would eliminate any potential impacts from sediment. The unnamed drainage on West Pit Road may be temporary impacted if this segment of the road needs to be widened. However, no fish are present in this stream.

Noxious Weeds

While no Class A weeds have been observed in the Project Area, several Class B and C weeds are present. Noxious weeds can threaten the general ecological health and diversity of native ecosystems. Noxious weed infestations are the second leading cause of wildlife habitat degradation.

Because many weeds are adapted to disturbed conditions and can establish immediately after construction, constructing the Project could foster the spread of noxious weeds throughout the Project Area. Noxious weeds would be managed within the Project Area. By implementing BMPs, weeds are not anticipated to spread further as a result of the development of the Project.

Operation

Habitats

Table 3.4-10 shows the permanent impacts of the Project to the habitat types found on the site. Operation of the Project would result in the permanent removal of 60.69 acres of habitat. Operation of the project would result in no further impacts to habitats on the project site.

Wetlands

No wetlands or wetland buffers are located within the Project operation area. Therefore, no wetlands or buffers are expected to be impacted by operation of the Project.

Special Status Plant Species

No impacts to special status plant species are anticipated from the operation of the Project.

Special Status Wildlife Species

In order to determine which species (including special status species) are most at risk for turbine fatalities, a relative index to collision risk \( R \) was calculated for bird species observed in the survey area using the following formula:

\[
R = A \cdot Pf \cdot Pt
\]
Where $A_i$ = mean use for species $i$ averaged across all surveys, $P_f$ = proportion of all observations of species $i$ where activity was recorded as flying (an index to the approximate percentage of time species $i$ spends flying during the daylight period), and $P_t$ = proportion of all flight height observations of species $i$ within the rotor-swept height. This is a relative index, which only illustrates which species may be the most susceptible to turbine fatalities. For the Project, the exposure index ranges from 0.29 on the high end (red crossbill) to 0 for many species (indicating that they were recorded on the site but not flying within the rotor swept area. If a species was recorded on the site, but never flying at all, then the exposure index would not be applicable. Exposure indices for all species across all years of survey can be found in Appendix C-4.

This index does not account for differences in behavior other than flight characteristics (i.e., flight height and proportion of time spent flying). In this impacts section, point count data were used to establish diurnal indices of avian use, and how these indices compare to other wind resource areas in the United States.

**Bald Eagle.** Bald eagles, although now fairly common in Washington State, are likely uncommon visitors to the Project Area. They are unlikely to nest or forage within the Project Area because there is no suitable habitat. An exposure index of 0.02 was calculated for the bald eagle (Appendix C-4). The potential for ongoing occurrence of bald eagle in the Project Area is very low. The potential for bald eagle fatalities as a result of turbine strike is also considered to be extremely low.

**Golden Eagle.** Two golden eagles were recorded in the Project Area during the fall of 2004. One occurred within the rotor-swept area and one was above. The golden eagle’s exposure index at Whistling Ridge is reported to be less than 0.01 (Appendix C-4). Therefore, golden eagles are considered to be at relatively low risk for collision with turbines at this site.

Golden eagles typically soar at a height within the rotor-swept area of most modern turbines, and swoop to the ground to capture prey. Golden eagles have recently experienced their first mortality at a wind turbine site in Washington State (Durbin 2009). Numerous golden eagles have been killed at the Altamont wind turbine project in California, indicating that this species is susceptible to turbine collision. Golden eagles have experienced mortality greater than would be anticipated based on their level of occurrence at Altamont Pass (Appendix C-4).

The creation of cleared areas re-vegetated with low growing herbaceous species around turbines may increase the risk of golden eagles entering the rotor-swept area if they forage for prey located beneath turbines. However, given their rare occurrence in the Project Area, the potential for golden eagles to experience a turbine collision is extremely low.

**Northern Goshawk.** Extensive surveys over four years recorded no goshawks in the Project Area, indicating that if they do occur, it would be extremely rare. Based on these years of species specific surveys using multiple methodologies, they were recorded more than would be expected during baseline surveys in 2004 and 2006. Based on those records, the exposure index for northern goshawk at the Project Area is reported to be 0.02. This includes the occurrence of five individuals, four of which were flying within the rotor swept area. Similar to the golden eagle, this species may be at risk of increased foraging activity in open areas around turbines because they hunt for prey that occurs on the ground in cleared areas. However, given their rare
occurrence in the Project Area, the potential for turbine related fatalities for this species is extremely low.

**Northern Spotted Owl.** The Applicant has sited its proposed Project to avoid habitat areas deemed critical to the northern spotted owl or essential to its recovery. Surveys conducted pursuant to the USFWS protocol indicate that spotted owls are not present in or near the Project, and that nearby historical sites are no longer occupied pursuant to USFWS Protocol and state law. Because there are no northern spotted owls or activity centers present in the Project Area, no Project construction impacts are expected. Finally, the Project would not impact the White Salmon SOSEA’s 40 percent suitable habitat level and therefore is not restricted by Washington’s forest practice regulations. Given the extensive record and review, this Project does not pose a risk of taking northern spotted owls under Endangered Species Act Section 9.

**Western Gray Squirrel.** No impacts to western gray squirrels are anticipated from operation of the proposed Project.

**Olive-sided Flycatcher, Pileated Woodpecker, and Vaux’s Swift.** These three species are encompassed in the bird discussion under “Other Wildlife.”

**Keen’s Myotis and Townsend’s Big-Eared Myotis.** These two bat species are encompassed in the bat discussion under “Other Wildlife.”

**Other Wildlife Species**

**Birds.** Potential operation-related impacts to avian species include turbine collision and displacement. Based on the exposure index derived from abundance and flight behavior, the species most likely to collide with wind turbines located at the Project are red crossbills (R = 0.29), American robin (R = 0.14), common raven (R = 0.23), and western bluebird (R = 0.11). The full list of species and their exposure index can be found in Appendix C-4. In addition, the revised report “Analysis of Cumulative Impacts on Avian, Bat and Habitat Associated with Wind Energy Development in the Columbia Plateau Ecoregion of Eastern Washington and Oregon” (West 2010) prepared for Klickitat County can be found in Appendix C11 of this FEIS. For an updated cumulative impacts analysis that takes into consideration wind energy development within forested habitats of western WA, please refer to Section 3.14.3.5.

The highest index for any raptor was 0.05 for red-tailed hawk, indicating a risk approximately six times lower than for the red crossbill. A regression analysis using data collected from the Whistling Ridge site and 13 other new-generation wind turbine projects found a significant correlation between raptor use and raptor mortality. Based on this analysis and surveys in the Project Area, the estimated a raptor/vulture fatality rate is zero per MW/year, which is an extremely low estimate compared to many wind projects (Appendix C-4). The Applicant’s consultants have generally reported a range of mortality for predictions, as was done in the baseline report for the proposed Project, where the 90 percent prediction interval around the estimate was 0 to 0.25 raptor fatalities/MW/year. Further, data collected from the Project Area indicate that the area is not within a major migratory pathway, at least during fall migration.

Vaux’s swifts, western bluebirds (a State Monitor species), and olive-sided flycatchers were commonly observed flying at rotor-swept heights, and some turbine-related mortality may occur for these species over the life of the Project. One prairie falcon and multiple turkey vultures...
(both State Monitor species) were observed at rotor-swept heights. Turkey vultures are known to have very low susceptibility to turbine collisions (Orloff and Flannery 1992). Pileated woodpeckers were recorded on the site, but not flying. Osprey (a State Monitor species) was recorded during northern goshawk surveys, which was separate from the baseline avian studies and therefore not included in the exposure index calculations.

It is unlikely that the Project would have any negative impacts on population levels on and near the Project Area. According to the National Academy of Sciences (2008), there is no evidence that “measurable demographic changes to bird populations in the United States” is occurring from fatalities at wind developments. Higher numbers of Vaux’s swifts and western bluebirds were recorded during fall migration, whereas olive-sided flycatcher appears to primarily use the Project Area for breeding.

Waterfowl, waterbirds, and shorebirds were not observed using lands within the Project Area during this study, and mortality involving this group is expected to be rare. Based on abundance, passerines are expected to make up the largest proportion of fatalities at the Project. Post-construction mortality data collected at other wind projects in Washington and Oregon indicate that less correlation between pre-construction surveys and turbine-related mortality is observed in non-raptor species. The lack of correlation may be because most fatalities are among nocturnal migrants that are not accounted for during surveys.

The avian use information for the Project Area is based on detections of birds seen and/or heard calling. Because songbirds are less vocal during fall, this information may be skewed toward summer use. Similarly, the level of night migration for species associated with the Project Area is also not known. Risk analyses presented above provide some insight into which species are most vulnerable to turbine collision; however, estimates are based on abundance, proportion of daily activity budget spent flying, and flight height of each species. Observations were made during daylight hours, and do not take into consideration flight behavior or abundance of nocturnal migrants. Further, the analysis does not account for varying ability among species to detect and avoid turbines, habitat selection, or other factors that may influence exposure to turbine collision. As a result, actual risk may be lower or higher than indicated by these estimates (Orloff and Flannery 1992).

Bats. It is likely that some bat mortality would occur during operation; however, mortality estimates are difficult due to our lack of understanding of why bats collide with wind turbines (Kunz et al. 2007, Baerwald et al. 2008). Several factors may aid in the assessment of potential impacts to bats, including site-specific habitat and topography, species composition, and activity patterns. The following impact assessment was completed by examining site-specific habitat features and bat acoustic data collected to date. Additional insight from investigations conducted at other wind projects is presented where relevant. The revised report “Analysis of Cumulative Impacts on Avian, Bat and Habitat Associated with Wind Energy Development in the Columbia Plateau Ecoregion of Eastern Washington and Oregon” (West 2010) prepared for Klickitat County, is included as Appendix C-11 of this EIS. For an updated cumulative impacts analysis that takes into consideration wind energy development within forested habitats of western Washington, please refer to Section 3.14.3.5.
The number of bat detections varied greatly between the three survey years. This is based on variation in habitat surveyed and the height of detector placement. Overall, the majority of detected species were low-frequency species, such as big brown and silver-haired bats. Hoary bats made up 8.2 percent of all passes by low-frequency species. Based on studies from other wind energy projects in the Pacific Northwest, turbine fatalities would be most expected from hoary bats and silver haired bats. Big brown bats are relatively uncommon at wind turbine fatalities. At elevated stations meant to reflect the rotor-swept area, low-frequency species were again recorded in much higher numbers than high-frequency species. This likely reflects migration flight heights and foraging preferences.

The timing of peak bat activity on the proposed Project Area (portions of July and August) does not coincide with when the highest levels of bat mortality have been documented at other wind projects in the US. Fatality studies have shown a peak in mortality in August and September and generally lower mortality earlier in the summer (Johnson 2005, Arnett et al. 2008). While the survey effort varies among the different studies, the studies that combine Anabat surveys and fatality surveys show a general association between the timing of increased bat call rates and timing of mortality, with both call rates and mortality peaking during the fall (Kunz et al. 2007). The highest use of the Project Area occurred in July and August, prior to the time that most bat mortality occurs at wind resource areas in the Pacific Northwest as well as throughout the US.

High bat activity in July and August is likely due to use of the Project Area by local bats during the reproductive season, when pups are being weaned and foraging rates are high. Activity beyond mid-August likely represents movement of migrating bats through the area. Activity by hoary bats also was substantially higher in July, and dropped off significantly beginning in early August. After August 31, activity for all bats was very low relative to earlier dates, indicating that most bats had left the area for winter hibernacula or warmer climates. These data indicate higher use of the Project Area by resident populations of bats, rather than by migrants passing through the area. Further, high bat activity levels during the breeding season, as seen in the Project Area, do not equate to high bat fatality rates. Low mortality has been documented during the breeding season at several wind projects, even when relatively large bat populations were present in the area (Fiedler 2004, Gruver 2002, Howe et al. 2002, Johnson et al. 2004, Schmidt et al. 2003).

Finally, no known large bat colonies are present near the proposed Project. The nearest known hibernaculum is located near the town of Trout Lake, nearly 20 miles north of the proposed Project (B. Weiler, personal communication). No significant peaks in bat activity, suggesting high migration activity, were noted during the August-September time frame that bats migrate. The project site does not contain topographic features, such as canyons, that may funnel migrating bats toward corridors where turbines would be placed. No turbines would be constructed near wetlands or ponds, and cleared areas surrounding turbine strings would closely mimic clearcuts or young reforested areas, where to date, recorded bat activity levels in the Project Area were the lowest.

Some bat fatalities are anticipated as a result of the operation of the proposed Project. Variable levels of recorded use by bats across years, habitats and recording height above ground indicate that the extent of impacts is difficult to predict at this time.
**Amphibians/Reptiles.** No impacts are anticipated to amphibians or reptiles as a result of Project operation.

**Mammals.** Because data on impacts to big game as a result of wind project operation is limited, it is difficult to predict the impact of the proposed Project on wildlife using priority habitats on the proposed Project Area. Additional coordination with WDFW is ongoing, and would continue to address this resource.

**Fish.** No impacts are anticipated to fish as a result of Project operation.

**Noxious Weeds**

The spread of noxious weeds is not anticipated to occur as a result of Project operation with BMPs in place.

**Project Decommissioning**

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least 90 days prior to the beginning of site preparation. A detailed site restoration plan is required within 90 days of Project termination. The initial site restoration plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is suspended or terminated during construction or before it has completed its useful operating life. The initial site restoration plan would include or parallel a decommissioning plan for the Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential changes to wetlands, vegetation, wildlife habitat, and noxious weeds. If impacts to biological resources are anticipated as a result of site restoration and Project decommissioning, mitigation measures would be proposed as part of the plan.

**3.4.2.2 No Action Alternative**

Under the No Action Alternative the Project would not be built. Timber harvest would still occur within the proposed Project boundary, which would continue to affect habitats and potentially increase the spread of weeds. However, there would be no increased avian or bat fatalities from turbine operations.

Other power generation facilities could be constructed and operated in the region to meet long-term needs for power, including other wind projects or generation using fossil fuels. Fossil fuel combustion would affect vegetation, wetlands, wildlife, and threatened and endangered species, including impacts related to carbon dioxide emissions. The significance of such impacts would depend on the site-specific locations and design of such facilities.
3.4.3 MITIGATION MEASURES

- The following mitigation measures are identified to avoid, minimize, and compensate for potential impacts to biological resources during construction and operation to the extent feasible.

- Avoid and minimize the use of overhead collector lines, which create areas where birds may congregate and perch, thus decreasing the potential for turbine collisions.

- Use of tubular turbine towers, avoiding the lattice type towers which creates areas where birds may congregate and perch, thus decreasing the potential for turbine collisions.

- Use of un-guyed meteorological towers, reducing the potential for bird collision with wires.

- Minimize the use of turbine lighting in the Project Area, thereby reducing the potential for birds and bats to be disoriented by lights or attracted to turbines.

- Install newer generation up-wind turbines.

- Utilize certified "weed free" straw bales during construction to avoid introduction of noxious weeds.

- Re-seed all temporarily disturbed areas with an appropriate mix of native plant species as soon as possible after construction is completed to accelerate the re-vegetation of these areas and to avoid the establishment and spread of noxious weed species.

- Implement a noxious weed control program, in coordination with the Skamania County Noxious Weed Control Board, to control the spread and prevent the introduction of noxious weed species.

- Conduct raptor nest surveys prior to construction during the breeding season (approximately April to July) in order to avoid or minimize impacts to any raptors potentially nesting in or near the Project Area. Construction activities requiring the surveys would include those that would remove forested areas and/or require the use of heavy equipment substantial enough to potentially disturb nesting activities.

- Implement a two year minimum post-construction avian mortality study.

- Convene a Technical Advisory Committee to evaluate the mitigation and monitoring program and determine the need for further studies or mitigation measures. The Technical Advisory Committee would be composed of representatives from WDFW, USFWS, Skamania County, and the Applicant. The role of the Technical Advisory Committee would be to coordinate appropriate mitigation measures, monitor impacts to wildlife and habitat, and address issues that arise regarding wildlife impacts during construction and operation of the Project, including potential adaptive management.
opportunities. The post-construction monitoring plan would be developed in coordination with the Technical Advisory Committee.

- Coordinate with WDFW for potential impacts to big game species (deer and elk), if appropriate.

- Prepare a SWPP for both the construction and operation phases of the project and submit to EFSEC for approval.

### 3.4.4 UNAVOIDABLE ADVERSE IMPACTS

The proposed Project would result in permanent loss, temporary disturbance and fragmentation of existing habitat for a number of wildlife species. These impacts, while unavoidable, would take place in landscape of managed timber lands which has for many years and would continue to be a fragmented environment with ongoing disturbance. There are no impacts to wetlands, and any particularly sensitive areas would be avoided during micrositing of the turbines.

**No population impacts are expected to birds through turbine collisions. Adequate information is not known on bat population sizes to determine whether population response would be anticipated.**

The proposed project would cause mortality to birds and bats through turbine collisions. However, the level of mortality is not anticipated to be sufficient to negatively affect the population viability of any single species.

It appears unlikely that the Project would cause any mortality to a threatened or endangered species. Extensive surveys for northern spotted owl and northern goshawk have been conducted throughout the Project Area and both species are considered either completely absent or extremely rare. Golden eagles were recorded during surveys in 2004, but not in more recent surveys. Bald eagles were recorded in the winter of 2008 and summer of 2009. The potential for ongoing occurrence of either golden or bald eagles is considered extremely rare.

3.5 ENERGY AND NATURAL RESOURCES

This section describes potential impacts to energy resources.

3.5.1 AFFECTED ENVIRONMENT

3.5.1.1 Region

Regional Demand

In September 2009, the Northwest Power and Conservation Council released the Draft Sixth Northwest Power Plan (NWPCC 2009), which contains projections for regional power demand. The plan notes that regional population is likely to increase from 12.7 million in 2007 to 16.3 million by 2030. Demand for electricity is expected to grow, in part as a result of this population growth. The Draft Sixth Northwest Power Plan states:

The Pacific Northwest consumed 19,000 average megawatts or 166 million megawatt-hours of electricity in 2007. That demand is expected to grow to 25,000 average megawatts by 2030 in the Council’s medium forecast. Between 2007 and 2030, demand is expected to increase by a total of 6,500 average megawatts, growing on average by 270 average megawatts, or 1.2 percent, per year.

The cost of energy of all types is expected to be significantly higher over the next twenty years than during the 1980s and 1990s. Cost increases would be driven by increasing demand and the fact that the cost of finding and producing new energy sources is higher than for existing supplies. Carbon emission taxes or cap-and-trade policies are likely to further raise energy costs. The Northwest Power and Conservation Council predicts that wholesale electricity prices are expected to increase from about $45 per megawatt-hour in 2010 to $85 by 2030 (2006$).

14 The Northwest Power and Conservation Council released their Sixth Northwest Power Plan in February 2010. The FEIS continues to reflect the information in the Draft Sixth Northwest Power Plan. For the final version of the Power Plan, see the Northwest Power and Conservation Council’s website at http://www.nwcouncil.org/energy/powerplant/6/default.htm.
Pacific Northwest Markets for Renewable Energy Resources

According to the Northwest Power and Conservation Council, much of the future demand for electricity in the region could be met through conservation. However, markets for renewable or “green” energy are still growing in the Pacific Northwest, and the Project can help to meet this growing demand. One driver for this shift is the establishment of RPS at the state level, which requires that utilities obtain a percentage of their power from renewable sources. For example, in 2006, voters in the Washington passed Initiative 937, which requires that by 2020 large public and private utilities must obtain 15 percent of their electricity from renewable resources, and undertake cost-effective energy conservation. In 2008, California increased its RPS goal from 20 percent to 33 percent renewable energy by 2020.

In addition to the RPS requirements, Washington law requires larger utilities in Washington to offer a voluntary “qualified alternative energy product,” essentially an electricity product powered by green resources, beginning in January 2012 (RCW 19.29A.090). State law defines a qualified alternative energy resource as electricity fueled by wind, solar energy, geothermal energy, landfill gas, wave or tidal action, gas produced during the treatment of wastewater, qualified hydropower, or biomass. As of 2008, 15 of the 16 utilities covered by the report had an active green power program with customers participating, and five additional utilities not covered by the law reported to the state that they were operating green power programs. Estimated sales of green power for 2008 were up 17 percent over 2007. Wind powered electricity represented 83.3 percent of green power sales (WUTC 2008).

Bonneville Power Administration Transmission System

BPA owns and operates 15,000 miles of power lines that carry power from the dams and other power plants to utility customers throughout the Pacific Northwest. The BPA service area includes Oregon, Washington, Idaho, Western Montana, and small portions of Wyoming, Nevada, Utah, California, and Eastern Montana.

Electric power plants require an interconnection with a high-voltage electrical transmission system for delivery to purchasing retail utilities. BPA owns and operates the FCRTS, which comprises more than three-fourths of the high-voltage transmission grid in the Pacific Northwest, and extra regional transmission facilities. BPA considers and grants interconnection requests to the FCRTS in accordance with its Open Access Transmission Tariff. Current and proposed wind project interconnections to BPA transmission facilities in the vicinity of the Project Area are shown in Figure 3.14-1. Under BPA’s tariff, BPA offers transmission interconnections to the FCRTS to all eligible customers on a first-come, first-served basis, with a decision on whether or not to make this offer subject to environmental review under NEPA.

3.5.1.2 Project Area

The Project would be located north of the Columbia River. The Columbia River corridor is an area of good wind energy potential that currently supports several successful wind power projects. The Columbia River Gorge provides a low-elevation connection between continental air masses in the interior of the Columbia Basin east of the Cascade Range and the maritime air of the Pacific Coast. Especially strong pressure gradients develop along the Cascades and force the air to flow rapidly eastward or westward through the Gorge.
Electric service for the Project Area is provided by Skamania County Public Utility District #1, which obtains electricity from the Federal Columbia River Power System (FCRPS), the series of hydroelectric projects along the Columbia River, through BPA. Backup power is obtained from Condit Dam, which is scheduled to be decommissioned in 2010. In July 2009 the Public Utility District sought intervener status with EFSEC to argue in favor of the Project, based on the ability of the Project to provide backup power to the Public Utility District once Condit Dam is removed (EFSEC 2009). There is currently no utility service of any kind at the proposed Project Area.

The proposed Project Area is already heavily used by energy and other utilities. Two BPA high-voltage transmission lines cross the Project Area, a natural gas pipeline runs near the north border of the Project Area, and there are two communications towers within one mile of the Project Area.

3.5.2 IMPACTS

3.5.2.1 Proposed Action

Construction

The Project would consume limited amounts of energy and natural resources, primarily during construction. The electrical substation would be built immediately adjacent to the BPA lines, reducing the need to build new long-distance high-voltage transmission lines.

Estimated types and quantities of energy and natural resources consumed during construction are as follows:

- 19,250 gallons of fuel (diesel and gasoline) for construction equipment
- 3,700 tons of steel for turbine towers
- 1,000 tons of steel for tower foundation reinforcement
- 100,000 yards of gravel (aggregate) for roads and crane pads
- 10,000 cubic yards of concrete for turbine foundations
- 1.7 million gallons of water for road compaction, dust control, wetting concrete, etc., assuming plain water is used for dust control (this amount could be reduced through the use of lignin or other dust palliative if permitted by EFSEC)

The source of fuel for construction equipment and vehicles would be licensed fuel distributors or gas stations. Petroleum products, including vehicle and equipment gasoline and diesel fuels, and machinery lubricants are available and would be purchased from numerous commercial outlets in the Project vicinity. Water for construction would be obtained from a local source with valid water rights, as described in Section 3.3 Water Resources. Concrete would be purchased from existing suppliers located near the Project Area. Electricity for construction equipment would be provided from portable generators.
Bulk materials such as aggregate gravel and sand, in addition to soils, would be supplied locally from existing quarries. Other building materials, equipment, and other operational commodities would be purchased from equipment and material suppliers. The largest resource use would be steel and concrete. Diesel fuel and electricity also would be consumed during construction. The amounts of all of these resources would be small compared to existing supplies, and none are expected to affect availability or market supply.

Nonrenewable resources in the Project vicinity are primarily gravel extracted from local sources and used locally. Primary consumption of these resources is related to construction projects (sand, gravel, and other mineral resources as used in steel, aluminum, concrete, and other building products). Several gravel pits and quarries are located near the Project Area. These would be adequate to supply the needs of the Project.

Renewable resources are materials that can be regenerated, such as wood, other fibers, wind, and sunlight. The primary renewable resources in the Project Area are timber and wind. The Project Area, including the Project Area, has been used for the renewable production of forest products for many years. The addition of the Project would diversify this renewable resource-based business by using a second, compatible renewable resource, the wind energy of the site. The Project would shift approximately 56 acres of commercial forest land to non-forest uses for the Project Area roads and the turbine corridors. In the context of the 1,152-acre site and the large areas of surrounding area in private and Washington State timber management, this reduction would not affect the availability of timber as a renewable resource.

**Operation**

Operation of the Project would consume limited amounts of energy and nonrenewable natural resources. During operations, electrical energy from Skamania County Public Utility District #1 would be consumed on a limited basis during times when the wind generated on site is insufficient to power warning lights required by the Federal Aviation Administration and security lights. Some electricity would be used at the Operations and Maintenance and substation facilities. In addition, turbines require electrical energy to run lubrication pumps and cooling systems, electrical monitoring systems, and position motors when wind speeds are below generation levels.

- Types and quantities of energy and natural resources consumed during operations are as follows:
  - Fuel for operations and maintenance vehicles (approximately 8,500 gallons annually)
  - Minor quantities of lubricating oils, greases and hydraulic fluids for the wind turbine generators
  - Electricity for Project operations (less than approximately 600 kilowatt hours per wind turbine generator per month)
  - Water for use at the Operations and Maintenance facility and periodic maintenance of turbine blades (less than 5,000 gallons per day)
Electricity for Project operations would mostly be generated by the approximately 75 MW of electricity created by the Project itself. Wind facilities have a very high “energy payback” (ratio of energy produced compared to energy expended in construction and operation), and wind’s energy payback time is one of the shortest of any electrical generation technology. It takes approximately three to eight months, depending on the wind speed at the site, for a wind facility to produce the total amount of energy used to construct the equipment and build the Project (AWEA 2007). The Applicant expects this to be true for the Project as well.

During periods when the wind turbines are not generating power, electricity would be purchased from the Skamania County Public Utility District #1.

The impact of this proposed Project to the regional electric demands can best be seen by a recent Northwest Power and Conservation Council evaluation of projected electrical demand in the region. The NPCC found that a medium forecast predicts a demand of about 5,300 MW by 2025 with a range of about minus 2,500 MW to a high of about plus 7,000 MW. The medium forecast represents a growth of about 1 percent per year. Given the regional energy needs and the unique convergence of gas pipelines, wind energy, and transmission lines in Klickitat County, it is reasonable to estimate that the County could produce a portion of the projected increased energy demand. Currently, the regional power resources come from the following energy technologies:

- Hydroelectric, 55 %
- Coal fired thermal, 19 %
- Nuclear power, 5 %
- Imports, 8 %
- Gas fired combustion turbines, 3 %
- Non-Utility generation, 6 %
- Miscellaneous, including wind power, 4 %

The Klickitat County Energy Overlay Zone Final EIS\textsuperscript{15}, released by the Klickitat County Planning Department, also recently evaluated the projected energy demand in Klickitat County, Washington, the county immediately adjacent to Skamania County. The Klickitat County Planning Department found that the technologies that are currently being used within Klickitat County include hydroelectric, gas fired combustion turbines, biomass fired turbines, and wind energy. These energy technologies are expected to continue to be developed in the County (through the year 2024) and include:

- Seven 250 MW or five 350 MW natural gas thermal projects;

\textsuperscript{15} See: http://www.klickitatcounty.org/default.asp
- Two 50 MW biomass projects;
- Four wind power projects with total generating capacity of 1,000 MW; and
- Solar projects are anticipated to be small in size and number.

The proposed Project, although in a small way, would help meet the Project demand outlined by the NPCC as mentioned above through its wind power generation. Additionally, the proposed Project would be consistent with the types of projects that have been outlined within the Klickitat County Energy Overlay Zone Final EIS.

Studies of the projected impact of this proposed Project to the FCRTS have found that the North Bonneville-Midway 230-kV line interconnection provides sufficient capacity for the proposed 70 MW request. From the proposed BPA substation interconnection, the power flow would be directed 80% towards North Bonneville and 20% towards Midway. The contingency analysis for this interconnection request indicates that no overloads are anticipated to occur, and this proposed Project would not be expected to affect the operation of BPA’s transmission system.

**Project Decommissioning**

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least 90 days prior to the beginning of site preparation. The plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is suspended or terminated during construction or before it has completed its useful operating life. The plan would include or parallel a decommissioning plan for the Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential uses of energy and natural resources. If impacts to energy or natural resources are anticipated to occur as a result of site restoration and Project decommissioning, mitigation measures would be proposed as part of the plan.

**3.5.2.2 No Action Alternative**

Under the No Action Alternative, the proposed Project would not be built. The energy and water use for the Operations and Maintenance building would not take place. It is likely that the region’s power needs would be met through energy efficiency and conservation measures, existing power generation, or the development of new power generation. However, projections of the region’s power needs are discussed further in the Northwest Power and Conservation Council’s Sixth Northwest Power Plan. Base load demand would likely be filled through expansion of existing, or development of new thermal generation such as gas-fired combustion turbine technology. Other wind sources also could be developed. Such development could

---

occur at appropriate locations throughout Washington State. The impacts on energy and natural resources would depend on the type, location, and size of the facility proposed.

### 3.5.3 MITIGATION MEASURES

Adverse impacts to energy and natural resources are identified to be minimal and therefore no mitigation measures would be required.

### 3.5.4 UNAVOIDABLE ADVERSE IMPACTS

The Project would have minor unavoidable adverse impacts to energy and natural resources. The overall impact of the Project to energy and natural resources would be positive, since it would provide the region with low-cost, clean, renewable energy, in accordance with state and national policies and priorities.

### 3.5.5 REFERENCES

### 3.6 PUBLIC HEALTH AND SAFETY

This section describes existing health and safety hazards at the Project Area and identifies potential health and safety risks from Project construction and operation. Risks discussed include fire or explosion, release of hazardous materials, vandalism, traffic accidents, turbine structural failure, ice throw, electric and magnetic fields, and shadow-flicker. Mitigation measures are identified for potential impacts.
3.6.1 AFFECTED ENVIRONMENT

3.6.1.1 Existing Health and Safety Risks

Existing health and safety hazards at the Project Area include those associated with the current commercial forestry operations on the site. Commercial forestry operations include some risks of fire and explosion from equipment operation, especially during dry summer months. Commercial forestry entails a small risk of leaks or spills of fuel, oil, or hydraulic fluid. There is also a small health and safety hazard related to logging trucks currently traveling to and from the site. During the dry summer months, there is some risk of fire from lightning.

Resources for responding to risks to environmental public health and safety include fire prevention, law enforcement, and emergency medical response.

3.6.1.2 Fire Prevention

The Project Area is currently used for commercial forestry and there are no structures on the site.

Two city fire departments (North Bonneville and Stevenson) and seven Skamania County fire districts provide fire protection to Skamania County residents. DNR also provides fire suppression services to forested areas in Skamania County, and would be the first responder to a fire emergency at the Project Area (J. Weeks, personal communication). Skamania County Fire District No. 3 (SCFD3) (also known as Underwood Fire District) provides fire protection and emergency response to a 20-square mile service area immediately south of the Project Area (D. Cox, personal communication). Although the Project Area is not formally within SCFD3’s service area (T. Skinner, personal communication), SCFD3 would likely respond to a fire at the Project Area, along with and in coordination with DNR (R. Hovey, personal communication). The Mill A Fire Department is also near the Project Area, and has a staff that includes less than six volunteer firefighters and no paid personnel (J. Carlson, personal communication).

The Project Area is located in DNR’s West Klickitat Area. The DNR work center closest to the Project Area is the Husum work center, which is staffed by one fire manager officer and one assistant fire manager (J. Weeks, personal communication). Other staff and equipment at the Husum work center includes six firefighters and two Type 6 wildfire engines (Fullerton and Helgerson 2008). The DNR response time to the Project Area would vary depending on the location of the engines and the type of fire emergency at the Project Area, but would range from 45 minutes to one hour (R. Hovey and J. Weeks, personal communications). The engines are usually assigned to work projects in the field.

SCFD3 is located in the unincorporated community of Underwood and is staffed by 17 volunteer firefighters. The SCFD3 service area is 20 square miles. Equipment at SCFD3 includes one each of the following: Type 1 engine, Type 2 engine, Type 3 engine, Type 7 engine, Type 2 tender, and Type 3 tender (Fullerton and Helgerson 2008). The Washington State Ratings Bureau rating for SCFD3 at the Project Area is “Unprotected – 10,” because the site is not located within the SCFD3 boundaries (T. Skinner, personal communication).

The Project Area is located outside of the Columbia River Gorge National Scenic Area. If an incident at or near the site, i.e., a wildland fire, threatens the area, the Columbia River Gorge
National Scenic Area fire agency could respond. The fire agency is equipped with three Type 6 wildfire engines, one fire prevention module, two command vehicles, two cooperative engines (with the DNR), and one cooperative engine (with the Oregon Department of Forestry). The Columbia River Gorge National Scenic Area fire agency has nine employees and is staffed seven days per week, July through September (Fullerton and Helgerson 2008).

Skamania and Klickitat Counties have jointly prepared a Community Wildfire Protection Plan through a Title III grant from the Secure Rural Schools and Self Determination Act (Klickitat and Skamania Counties 2006). This is a plan developed by a community in an area at risk from wildfire, with the goal of reducing the risk of catastrophic wildfire within the region.

Table 3.6-1 lists the fire departments that serve the site and surrounding area, along with the departments’ staff and equipment. These fire districts have mutual aid agreements with each other (J. Carlson, personal communication).

### 3.6.1.3 Law Enforcement

The Skamania County Sheriff’s Office provides law enforcement services in the Project vicinity. Sheriff’s Office headquarters are located in Stevenson, approximately 15 miles southwest of the Project Area. The response time from Sheriff’s Office headquarters to the Project Area is approximately 20 minutes.

The Washington State Patrol patrols SR 14 south of the site. Roads extending north of SR 14 are county roads, and are patrolled by the Sheriff’s Office. Table 3.6-2 provides information on the police departments serving the site area, including service area and number of officers.

### 3.6.1.4 Emergency Medical Services

Two ambulance companies provide emergency response services for the Project Area: Skamania County Emergency Medical Service and Skyline Ambulance. Skamania County Emergency Medical Services is the functioning entity of Skamania County Hospital District No. 1, which provides ambulance service to the residents of Skamania County. Skyline Ambulance is based at Skyline Hospital in White Salmon, and is equipped with three ambulance vehicles. Table 3.6-3 lists characteristics of the first response ambulance service providers for the Project Area.

<sup>a</sup> T. Skinner (personal communication): As rated by the Washington Surveying and Rating Bureau. The Bureau rates the level of fire protection provided by fire departments against four main elements: available water supply; logistical characteristics and makeup of the district fire department; available communications systems; and fire control and safety measures taken and ordinances in effect in the particular fire district. Ratings are used to evaluate fire protection availability for insurance purposes. Ratings range from 1 to 10, with class 1 representing the highest level of fire protection and class 10 the lowest level. Ratings were not available for the DNR or the Columbia River Gorge National Scenic Area Fire Agency.

Sources: Skyline Hospital (2008), Skamania County EMS (2008).

The two hospitals closest to the Project Area are Skyline Hospital in White Salmon (7 miles southeast of the Project) and Providence Hood River Memorial Hospital, directly across the Columbia River from White Salmon in the City of Hood River (8 miles southeast of the Project). Skyline Hospital is a 32-bed acute care hospital with a Trauma Level IV designation, serving western Klickitat County and eastern Skamania County. Services at Skyline Hospital include acute care, obstetrics, surgery, cardiopulmonary care, radiology and laboratory services, physical therapy, a pharmacy, and emergency services. Skyline Hospital owns and operates a three-vehicle ambulance service (Skyline Hospital 2008).

Providence Hood River Memorial Hospital is a 25-bed facility that provides cardio conditioning, counseling, diabetes treatment, a dialysis center, emergency services, obstetrics, radiology, laboratory services, nutrition, occupational medicine, a sleep center, and surgery.\(^\text{17}\)

3.6.2 IMPACTS

3.6.2.1 Proposed Action

Potential impacts to environmental public health may occur during construction or operation.

Construction

Construction impacts include the typical risks to health associated with the construction of an industrial facility, including fire or explosion, release of hazardous materials, vandalism, and accidents.

Fire or Explosion

The only structures proposed on the site are the turbine towers, associated transformers and substation, and the Operations and Maintenance facility. Project construction could temporarily increase the risk of fire at the Project Area and in the broader Project Area, as a result of the operation of vehicles and power equipment, which may cause fires through contact with dried plants during dry summer weather. Blasting may be used where solid rock is encountered during construction of turbine foundations or trenches for the underground electrical collection system. Blasting could create a fire hazard during dry weather.

As the landowner and a long-term commercial forestry business, the Applicant has maintained the ability to respond to fires on their forest land with dozers and water trucks, and would

\(^{17}\) See: http://www.providence.org/hoodriver/
continue to do so. Fire response by the Applicant would be supplemented by DNR, which provides fire protection on forest lands. DNR has resources in the area and responds to all wildland fires. DNR would likely respond to a structure fire in the woods, as would Underwood Fire District #3 and Mill A Volunteers. SCFD3 is the nearest local fire district. Eric Ziegler, District Chief, submitted a letter to EFSEC during the EIS scoping period stating that SCFD3 can provide service coverage to the Project Area to respond to fires without any reduction in service to their constituency. Mill A Volunteers is not a recognized fire district with a tax base but a volunteer fire company. Mill A Volunteers has joint responder agreements with Underwood Fire District and the DNR.

There are two locations being considered for the Operations and Maintenance facility site, one site next to the substation and the other at the bottom of West Pit Road. The West Pit Road site would have a lower fire risk and shorter response times for emergency services, since the facility would be along a county road.

Releases of Hazardous Materials

The risk of releases to the environment that would affect health would be similar to any large construction project. The primary potentially hazardous materials used during construction would be diesel fuel for construction equipment, lubricating oils and hydraulic fluids for the turbines, and mineral oil for the transformer at each turbine and the substation. Approximately 19,250 gallons of diesel fuel would be used during construction. Most trucks would fuel up off-site; some fuel would be transported to the site.

Each turbine would contain a small amount of hydraulic fluid, and would have a pad-mounted transformer containing approximately 500 gallons of mineral oil for cooling. The BPA substation would have either one or two transformers, each containing up to 12,000 gallons of mineral oil. These transformers would be filled during construction.

Should contaminated media be unexpectedly encountered during construction of the Project, work would be stopped, and an environmental specialist would be called in to characterize the nature and extent of the contamination and to determine how the work may safely be completed. Work would proceed only after measures approved by the WDOE and identified in the Hazardous Waste Management Plan are put in place to prevent the spread of contaminated materials and protect the health and safety of workers.

Vandalism

During construction, the presence of out-of-area workers could create a negligible increase in the risk of vandalism in the community. Vandalism of Project facilities and theft of equipment during construction also is a potential area of concern. Security provisions could include temporary fencing with a locked gate around the construction site; the use of site trailers for the temporary storage of special equipment or materials; and the use of outdoor lighting and motion-sensor lighting. Access to the Project Area would be controlled, and site visitors including vendors, equipment personnel, maintenance contractors, material suppliers, and all other third parties would require permission for access from authorized Project staff prior to entrance. These measures would help to reduce the potential for vandalism and other incidents at the Project Area that would require a response by local law enforcement agencies. The Applicant may contract for on-site security to supplement coverage by the Skamania County Sheriff.
Traffic Accidents

Project construction could lead to a slight increase in the chance of traffic accidents, due to the presence of a peak of 265 construction workers traveling to the site, along with the transport of construction materials and the turbine components. This impact would last a maximum of one year, with peak impacts limited to a several-month period in the summer. This risk would be minimal and similar to any construction project involving the use of heavy equipment and large structural components on the roadways. The Skamania County Sheriff or the Washington State Patrol would respond to traffic accidents. Medical response would be provided by the local ambulance services (Skamania County Emergency Medical Service and Skyline Ambulance) and the two local hospitals (Skyline Hospital in White Salmon and Providence Hood River Memorial Hospital in Hood River), which have capacity for additional patients.

Turbine Structural Failure

The risk of turbine structural failure during construction would be very small, and would be due primarily to problems in the assembly process, should a failure occur. The turbine supplier would be required to document and provide the quality assurance/quality control procedures used during manufacturing and assembly to minimize or eliminate the risk of failure.

Ice Throw

Ice storms, both mild and occasionally severe, may occur in the Project Area. During periods of ice build-up, the exposed parts of the turbine may be coated with ice. When a stationary blade accumulates ice followed by an increase in temperature, the ice on the blade can thaw. If the blades are stationary, the ice would fall near the turbine base, but once the blades begin to rotate, ice fragments may be thrown. Ice throw would not be a risk during construction because the turbines would not be operating.

Shadow Flicker

Shadow flicker caused by wind turbines is defined as alternating changes in light intensity as the moving blade casts shadows on the ground and objects, including windows at residences. Some health concerns have been raised about the effects of shadow flicker. Shadow flicker can only occur if the location of the turbine is close to a receptor that is in a position where the blades interfere with very low-angle sunlight. Shadow flicker would not be a risk during construction because the turbines would not be operational.

Electromagnetic Fields

Electrical transmission lines, distribution lines, and substations create electromagnetic fields. Electromagnetic fields also exist in nature and around all types of electrical devices and appliances. They are produced by the presence of differences in electrical potential (voltage) and the movement of charges because of the potential (current). This movement produces magnetic fields. The electrical and magnetic fields around electrical appliances and utility facilities are extremely low frequency. They have a significantly lower frequency (60 cycles per second, or Hz), than radio broadcast waves (0.5 to 100 million cycles per second) or electromagnetic energy from sunshine (1,000 trillion cycles per second). Electrical and magnetic fields would not be generated prior to completion of the Project other than by electrical generators used for temporary site power.
Operation

Potential health and safety concerns from operation of a wind energy facility include ongoing risks of fire or explosion, releases to the environment, vandalism or traffic accidents, along with concerns regarding turbine structural failure, tower failure, blade throw ice throw from the turbine blades, shadow flicker from the moving blades, and electrical and magnetic fields.

Fire or Explosion

Wild fires in the Project Area are relatively rare, and fire conditions are monitored continually by the DNR. During Project operation, fire protection would continue to be provided by the Applicant, DNR, Underwood Fire District, and Mill A Volunteers. Potential for fire would be lower once construction is completed, and would relate primarily to lightning and vehicle use during the dry summer months. These risks would be mitigated through appropriate operational practices. DNR has stated that resources for fire protection and suppression services are adequate to serve the Project during construction and operation (J. Weeks, personal communication).

Turbine fires are possible; however, with the types of modern wind turbines proposed for the Project, turbine malfunctions leading to fires in the nacelle are extremely rare. The turbine control system detects overheating in turbine machinery, and internal fires would be detected by these sensors, causing the machine to shut down immediately and send an alarm signal to the central supervisory control and data acquisition system, which would notify operators of the alarm by cell phone or pager.

Releases to the Environment

Operation of the Project would not result in the generation of regulated quantities of hazardous wastes. Since no fuel would be burned to power the wind turbine generators, there would be no spent fuel, ash, sludge or other process wastes generated. The only materials used during Project operations that present any potential for accidental spills are lubricating oils and hydraulic fluids used in the wind turbine generators and transformers.

- **Turbine Fluids.** The fluids within the turbines are checked by staff periodically and must be replenished or replaced on an infrequent basis (generally less than once per year and sometimes only once every five years). When replacing these fluids, the industry standard practice is for staff to climb up to the nacelle and remove the fluids in small (typically five-gallon) containers and lower them to the ground using a small maintenance crane built into the nacelle itself. The containers would then be transferred to a pickup truck for transport to the Operations and Maintenance facility for temporary storage (typically less than one month) before being picked up by a licensed transporter for recycling. Replacement fluids are added in the same method, only in reverse.

- **Replacement Fluids.** Small quantities of replacement fluids, typically no more than a few 50-gallon drums of lubricating oil and hydraulic oil, may be stored at the Operations and Maintenance facility for replenishing and replacing spent fluids. These fluids would be stored in appropriate containers. All operations staff would be trained in appropriate handling and spill prevention techniques to avoid any accidental spills. Because only small quantities of fluids are transported, added, or removed at any one time and are
stored for short periods of time, the potential for an accidental spill during routine maintenance is extremely limited.

- **Pad Mounted Transformers.** Each wind turbine generator has a pad mounted transformer located at its base. These transformers contain mineral oil, which acts as a coolant. Each pad mounted transformer contains up to 500 gallons of mineral oil. The transformer is designed to meet stringent electrical industry standards, including containment tank welds and corrosion protection specifications. Regular maintenance is performed on the transformers, including checking the condition of the coolant.

- **Substation Transformer(s).** The BPA substation would be equipped with either one or two transformers. Each substation transformer would contain up to 12,000 gallons of mineral oil for cooling. These transformers are designed to meet stringent electrical industry standards, including containment tank welds and corrosion protection specifications. The substation transformers are equipped with an oil level sensor that detects any sudden drop in the oil levels and send an alarm message to the central supervisory control and data acquisition system. Finally, the substation transformers are supported by a concrete vault to ensure that any accidental fluid leak does not result in any discharge to the environment.

It is anticipated that an Operation SPCC Plan would be submitted and approved by EFSEC prior to operation.

**Vandalism**

Vandalism of Project facilities and theft of equipment during operation is similar to that expected during construction. As with the construction period, the Project design would include site security measures including fencing and outdoor lighting, and the Applicant may contract for on-site security to supplement coverage by the Skamania County Sheriff.

**Traffic Accidents**

The risk of traffic accidents during operation would be low. The Project would employ between eight and nine operations staff; this number would not generate sufficient additional traffic to increase accident rates. Traffic accident response would continue to be provided by the Skamania County Sheriff and Washington State Patrol, with support by local ambulance services and hospitals as needed.

**Tower Failure**

Structural failure of the turbine tower is very rare, though some instances of turbine failure have been documented in older turbine models. A review performed for the Kittitas Valley Wind Project EIS located five reported instances of tower failure worldwide. There are at least 55,000 wind turbines installed world-wide (EFSEC 2007). One insurance company representative whose company insured over 12,000 turbines reported that he was not aware of any instances of the failure of tubular turbine towers (EFSEC 2007).

Tower failure can be attributed to improper design, manufacturing defects, extreme weather events, or the wrong application of technology. Reasons for tower collapse can vary depending
on conditions and tower type, but may include blade strikes, very strong winds, and improper maintenance. While structural failure is more damaging than blade failure, the consequences and risks to human health are far lower since risks are confined to within a relatively short distance from the turbine (Caithness 2006). There is only one recorded death from a tower collapse, which occurred in Sherman County, Oregon (a construction worker who died during the testing phase and not during operation). A six-month investigation found that the operating company “failed to properly instruct and supervise workers in the safe operation of tools and equipment. It also found that company procedures for working under potentially dangerous conditions fell short of OSHA [Occupational Safety and Health regulations]” (Hill 2008). The investigation did not find any structural problems with the tower itself.

Blade Throw

Cases of blade throw are rare and have generally been linked to improper assembly or exceedance of design limits (AWEA 2008). In those rare instances where towers or blades have failed, the failure typically results in components crumpling or falling straight down to the ground, although in a small number of cases blades or parts of blades have been thrown from the nacelle. There is limited data available on how far blade components would be thrown since blade throw is extremely rare. In testimony for the Kittitas Valley Wind Project, a representative from Vestas Wind Systems in Denmark stated that there are approximately 10,000 Vestas turbines installed and operating worldwide. There has been only one noted occurrence of blade throw, with a Vestas V39-500kW turbine in Denmark in 1992 where a blade was thrown 50 to 75 meters (approximately 165 to 245 feet) (EFSEC 2007). Based on this information, the Applicant determined that using a minimum of turbine tip height to define the minimum safety setback distance is sufficient to protect against blade throw.

For the Project, members of the public would not have access to the Project Area, and signs would be used to discourage unauthorized access. The tip height of the turbines would be approximately 426 feet. The property boundaries of the Project Area would be greater than 426 feet in distance to the nearest turbine in all but a few isolated cases. Exact distances from the turbines to the property boundary would depend on the final design and placement of the turbines; however, it is possible that the nearest turbine would be within this distance of the Project boundary for small parts of turbine strings A and B (on the west side of the Project Area), F and D (on the south side) and B and C (on the north side). However, most of this area is under control of the Applicant or in large-scale agriculture, and there are no residences within this buffer area:

- On the west side of the Project Area, there are six properties, of which only two are owned by a person or entity other than the Applicant. These two are owned by the State and managed by DNR. All these neighboring properties are managed as commercial forest land with no residential structures.
- On the south side, there are five adjacent off-project properties, located within the Scenic Area. Of these five properties, only one, totaling 29 acres, is owned by someone other than the Applicant. The 29-acre parcel is primarily managed as forest and orchard lands, with 1 acre used for residential purposes. The owner has received approval from Skamania County to relocate their existing home to within 50 feet of their north property line. This new location would bring the residence to within 2,000 feet of the closest
proposed turbine corridor. Except for this parcel, all adjacent lands to the south are in commercial timber production.

- On the north side, the land is owned by the State and managed for commercial timber harvest by the DNR.

The wind turbines for the Project would be equipped with sophisticated computer control systems to monitor variables such as wind speed and direction, air and machine temperatures, electrical voltages, currents, vibrations, blade pitch and yaw angles, etc. Each turbine would be connected to a central data control system. The system would allow for remote control and monitoring of individual turbines and the wind plant as a whole from both the central host computer or from a remote computer.

All turbines are designed with several levels of built-in safety and comply with the codes set forth by Occupational Safety and Health Administration and American National Standards Institute standards. The turbines would be equipped with two fully independent braking systems that could stop the rotor either acting together or independently. The braking system is designed to bring the rotor to a halt under all foreseeable conditions. The system would include aerodynamic braking by the rotor blades and by a separate hydraulic disc brake system. Both braking systems would operate independently such that if there is a fault with one system, the other could still bring the turbine to a halt. Remote restarting of the turbine would not be possible following an emergency stop. The turbine would be inspected in-person and the stop-fault reset manually to re-activate automatic operation. The turbines also would be equipped with a parking brake used to “park” the rotor while maintenance routines or stationary rotor inspections are performed.

**Ice Throw**

As noted above, during periods of ice build-up, the exposed parts of the turbine may be coated with ice. When a stationary blade accumulates ice followed by an increase in temperature, the ice on the blade can thaw. If the blades are stationary, the ice would fall near the turbine base, but once the blades begin to rotate, ice fragments may be thrown. The risk of impacts from ice throw is minimal. Most modern turbines include sensors that would shut down the turbine when ice build-up is detected. A 1998 study reported that there had been no injury from ice thrown from wind turbines (Morgan et al. 1998). A 2009 study reported one human injury due to ice-throw, although the specifics of the incident were not provided (Caithness 2009). As stated above, there are at least 55,000 wind turbines in operation world-wide.

Reported data on ice throws at other projects indicate that ice fragments were found on the ground from 50 to 328 feet from turbines (<33 to 197 feet blade diameter) and were in the range of 0.2 to 2.2 pounds in mass (Morgan et al. 1998, EFSEC 2007). When more than a few meters from the turbine, the risk of ice landing at a specific location was found to reduce quite quickly with the distance of the location from the turbine. It was also found that ice falls predominantly downwind of the rotor plane. Seifert et al. (2003) conducted risk analyses on ice throw primarily in Europe. The general conclusion was that wind turbines would not cause ice throw risks as they are normally set back from residences and roadways and that the hypothetical risk of being struck by ice is small. However, the actual throwing distance of the ice fragments would vary
based on many variables not included in this calculation, including rotor azimuth, rotor speed, local radius, ice fragment size and weight, and the wind speed.

Thus, a buffer based on tip height (approximately 426 feet) would provide adequate protection from ice throw. As discussed in the Blade Throw section above, the Project Area boundaries are usually farther than this distance from the nearest turbine, and where this is not the case the surrounding area is either under the control of the Applicant, managed for commercial timber harvest by Washington State, or managed for large-scale agriculture. The nearest residence is approximately 2,000 feet from the nearest proposed turbine string.

**Shadow Flicker**

Shadow flicker is the alternating change in light intensity when moving turbine blades cast shadows on the ground and objects, such as windows in residences. Shadow flicker is not caused by viewing the sun through rotating wind turbines blades or moving through the shadows of a wind energy facility, or sunlight reflected from turbine blades. Shadow flicker occurs when a turbine is located near a receptor (e.g., residence) with an unobstructed line of sight to the turbine, the sun is behind and perpendicular to the turning turbine blades and the receptor is located close enough to the turbine to be in its shadow.

The existence and intensity of shadow flicker are affected by a number of factors including:

- The strength of the sun as affected by cloud cover.
- The line of sight of the observer relative to the sun and the turbine. This is related to the sun’s height in the sky, which varies with latitude and longitude, time of day, and time of year.
- The distance between the observer and the turbine, which affects the distinctness of the shadows.
- The presence of obstructions such as buildings or vegetation.
- The orientation of the turbine depending on wind conditions. When the turbine is facing the sun, shadow flicker is greater behind the turbine; when the turbine is rotating in line with the sun, there is much less flicker (Committee for Renewable Energy 2008).

Potential shadow flicker from wind turbines can only occur when (1) the sun is very low in the sky; (2) a receptor is very close to the turbine; (3) the receptor is oriented toward a turbine; (4) the receptor has an unobstructed line of sight; and (5) the weather conditions include bright sun. When all these factors exist, they may produce a pulsating shadow which may or may not be perceptible. Shadow flicker frequency is related to the rotor speed and number of blades on the rotor, which can be translated into a “blade pass frequency” measured in alternations per second, or hertz (Hz). Although in some instances the flickering of light can induce epileptic seizures in people who are photosensitive (about 3-5 percent of the 1 percent of Americans who are epileptic are photosensitive), shadow flicker from wind turbines is too slow to induce epileptic seizures. Whether light flicker would provoke a reaction depends on its frequency, light intensity, visual area, image pattern, and color (Epilepsy Foundation 2009). Flicker frequency
due to a turbine is on the order of the rotor frequency, i.e., 0.6–1.0 Hz (NRC/NAS 2007). The flicker frequency that provokes seizures in photosensitive individuals is 5–30 Hz, well above the maximum of approximately 1 Hz for wind turbines. There is no scientific data or peer-reviewed studies that suggest a link between epileptic seizures and rotor blade alternatives.

Analyses conducted at other wind energy facilities approved by EFSEC (Kittitas Valley Wind Power Project and the Wild Horse Wind Power Project) examined the potential effects of shadow flicker for residents near the proposed projects and recommended certain measures for minimizing these effects. EFSEC found that as the distance between the wind turbine generators and residences increases, the perception of shadow flicker decreases or attenuates. At a distance beyond 2,500 feet, shadow flicker is considered to be imperceptible. Even if shadow flicker were a proven impact (as the Council found in the Kittitas Valley Wind Power Project case), none of the planned turbines are within 2,500 feet of existing residences (Figure 3.7-1 Noise Level Contours in Section 3.7 shows the locations of the closest residences.). If shadow flicker were found to occur, operational controls could be implemented to completely eliminate this perceived impact. For instance, turbine speed or orientation could be controlled during specific periods.

**Electromagnetic Fields**

The Project would include 34.5-kV collector lines and systems, primarily located underground. There would be a new collector substation located adjacent to BPA’s existing North Bonneville to Midway 230-kV transmission line and a new interconnection from the proposed BPA substation to the 230-kV transmission line.

Electrical transmission lines, distribution lines, and substations create electromagnetic fields, which also exists in nature and around all types of electrical devices and appliances. As shown in Table 3.6-4, much of typical daily exposure to electromagnetic fields from human-made sources is a result of using electric home appliances. Electromagnetic field strength is expressed with a unit of measure called a milligauss (mG), and is measured using a special monitoring device. The strength of electromagnetic fields falls rapidly as one moves away from the source.

* Gauger, J.R. (1985), Silva et al. (1988)

Electromagnetic fields from the Project would be lower than those of many common household appliances and would not have health and safety impacts. Electromagnetic field readings for
items commonly found in homes compared to electrical transmission lines are shown on Table 3.6-4.

Given the low strength of electromagnetic fields from the Project and the distance to the nearest residences and the Operations and Maintenance facility, the Project would have no impacts from electromagnetic fields.

Other Potential Impacts

Other potential adverse impacts to environmental public health during operation could occur from the following:

- **Weather.** Weather emergency includes hail, high winds, thunderstorms, extreme cold weather, and any other naturally occurring weather situation that may endanger equipment, or require adjustments to the normal operations of the facility. Risks to personnel at the Project would be minimized through preparation of and implementation of an Emergency Plan that includes planning for weather contingencies.

- **Geological.** This type of emergency deals with seismic activity and related geological phenomena. As discussed in Section 3.1 Earth, the likelihood of earthquake at the site is very low.

- **Security.** This type of emergency includes bomb threats, civil unrest, sabotage, or any other man made threats to the facility or personnel. The risk of a security emergency in this location and to this type of facility is considered very low.

- **Lighting.** The FAA requires structures over 200 feet be equipped with red or white flashing lights mounted on the nacelle of a wind turbine to avoid aircraft collisions during the day and night.

**Project Decommissioning**

The health and safety risks associated with decommissioning would be similar to those during the construction process. In compliance with WAC 463-72 Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is suspended or terminated during construction or before it has completed its useful operating life. The plan would include or parallel a decommissioning plan for the Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major public health environmental health issues presently anticipated. If impacts to public health environmental health are anticipated to occur as a result of site restoration and project decommissioning, mitigation measures would be proposed as part of the plan.

**3.6.2.2 No Action Alternative**

Under the No Action Alternative, the proposed Project would not be built. The risk of fire due to lightning strikes or human activity in the general area would continue at their present levels, as
would the risk of hazardous waste release, vandalism, and traffic accidents. The electrical
energy that would otherwise be produced by the Project would need to be obtained from another
generating source.

3.6.3 MITIGATION MEASURES

The following mitigation measures are identified to avoid, minimize, and compensate for
potential impacts to public health and safety to the extent feasible.

- Prepare Emergency Plans for the Project containing the following components:
  - **Fire Protection and Prevention Plan.** A Fire Protection and Prevention Plan would
    be developed for EFSEC approval and implemented, in coordination with the
    Skamania County Fire Marshall and appropriate agencies. As part of the plan, the
    construction manager would be responsible for staying abreast of fire conditions in
    the Project Area by contacting DNR and implementing any necessary fire
    precautions.
  
  - **Personal Injury Response Plan.** Procedures would be developed for construction,
    operation and maintenance of the Project to describe procedures to be followed in the
    event of a personal injury, including who is to be alerted, contacting 911, how to alert
    others in the immediate vicinity, remaining with the employee, and administering first
    aid until medical assistance arrives.
  
  - **Safety Plan.** Prior to the commencement of any construction work, the construction
    contractor would be required to prepare a Safety Plan that would apply to all
    contractor and subcontractor personnel working at the site. The plan would be
    designed to ensure compliance with all laws, ordinances, regulations, and standards
    concerning health and safety. The contractor would assign a safety manager with the
    authority to issue a “stop work” notice when health and safety issues arise.
  
  - **SPCC Plan.** While storage of chemicals on site would be minimal, the Project could
    require an SPCC Plan that would protect groundwater. The SPCC Plan would apply
    to both construction and operation if hazardous materials were stored on site in
    quantities sufficient to trigger the plan requirement.
  
  - **Hazardous Waste Management Plan.** Hazardous materials to be used or stored on
    site would be limited to small quantities of materials used for maintenance (cleaning
    and painting), lubrication of equipment, and possibly fuel. During construction, the
    construction contractor would be required to prepare a Hazardous Waste Management
    Plan that complies with state and federal hazardous waste management laws for
    handling, storage, and disposal. A similar plan would be prepared and implemented
    for operation.
  
- Report conditions affecting the safety of the Project to EFSEC, including any condition,
  event, or action that might compromise the safety, stability, or integrity of any facility or
  the ability of any equipment to function safely; or that might otherwise adversely affect
  life, health, or property.
- Develop agreements related to emergency planning with Skamania County Department of Emergency Management prior to Project construction. This agreement would be provided to EFSEC and attached to the Emergency Plan prior to implementation.

- Comply with all applicable local, state, and federal safety, health, and environmental laws, ordinances, regulations, and standards. Some of the main laws, ordinances, regulations and standards that would be reflected in the design, construction, and operation of the Project are as follows:
  - Occupational Safety And Health Act of 1970 (29 USC 651, et seq.) and 29 CFR 1910, Occupational Safety and Health Standards;
  - Uniform Fire Code;
  - Americans with Disabilities Act;
  - Uniform Fire Code Standards;
  - Uniform Building Code;
  - National Fire Protection Association design standards for the requirements of fire protection systems;
  - National Institute For Occupational Safety And Health requirements that safety equipment carry markings, numbers, or certificates of approval for stated standards;
  - American Society of Mechanical Engineers plant design standards.

- American National Standards Institute plant design standards:
  - National Electric Safety Code;
  - American Concrete Institute Standards;
  - American Institute of Steel Construction Standards;

- Utilize the following measures to mitigate the risk of fire or explosion:
  - The construction manager would be responsible for staying abreast of fire conditions in the Project Area by contacting DNR and implementing any necessary fire precautions;
  - A Fire Protection and Prevention Plan would be developed for EFSEC approval and implemented by the Applicant, in coordination with the Skamania County Fire Marshall and appropriate agencies;
  - Both the wind turbine generators and the substation would be equipped with lightning protection systems.

Table 3.6-5 lists sources of potential fire and explosion along with measures to mitigate the risk of either occurring.
Require that all on-site operations employees would be responsible for contributing to ongoing fire prevention in the Project Area through the following programs:

- Operational Safety Program;
- Operations Written Safety Program;
- Emergency Action Plan;
- Fire Prevention Plan.

Develop on-site emergency plans would be prepared for the Project in case of a major natural disaster or accident relating to or affecting the Project. The plans would describe the emergency response procedures to be implemented during various emergency situations that may affect the Project or surrounding community or environment. In addition to the above measures, the Applicant would:

- Provide detailed maps that show all access roads to the Project;
- Provide keys to a master lock system that would enable emergency personnel to unlock gates that would otherwise limit access to the Project;
- Use spark arresters on all power equipment, e.g., cutting torches and cutting tools;
- Inform workers at the Project Area of emergency contact phone numbers and train them in emergency response procedures;
- Carry fire extinguishers in all maintenance vehicles;
- Coordinate with DNR when the fire danger is high;
- Comply with equipment rules and regulations required by DNR for work conducted in wildland/forested lands.
### Table 3.6-5
**Fire and Explosion Risk Mitigation**

<table>
<thead>
<tr>
<th>Construction or Operation</th>
<th>Potential Fire or Explosion Source</th>
<th>Mitigation Measures</th>
</tr>
</thead>
</table>
| Construction and Operation | General Fire Protection | • All on-site service vehicles fitted with fire extinguishers.  
• Fire station boxes with shovels, water tank sprayers, etc. installed at multiple locations on site along roadways during summer fire season.  
• Minimum of one water truck with sprayers must be present on each turbine string road with construction activities during fire season. |
| Construction and Operation | Dry vegetation in contact with hot exhaust catalytic converters under vehicles | • No gas powered vehicles allowed outside of graveled areas.  
• Mainly diesel vehicles (i.e. w/o catalytic converters) used on site.  
• Use of high clearance vehicles on site if used off-road. |
| Construction and Operation | Smoking | • Restricted to designated areas (outdoor gravel covered areas). |
| Construction and Operation | Explosives used during excavation | • Only state-licensed explosive specialist contractors are allowed to perform this work—explosives require special detonation equipment with safety lockouts.  
• Clear vegetation from the general footprint area surrounding the excavation zone to be blasted.  
• Standby water spray trucks and fire suppression equipment to be present during blasting activities. |
| Construction and Operation | Electrical fires | • Use generally high clearance vehicles on site.  
• No gas powered vehicles allowed outside of graveled areas.  
• All major construction equipment used is to be diesel powered (i.e., without catalytic converters). |
| Construction and Operation | Lightning | • Specially engineered lightning protection and grounding systems used at wind turbines and at substation.  
• Footprint areas around turbines and substation are graveled with no vegetation. |
| Construction | Portable generators – hot exhaust | • Generators not allowed to operate on open grass areas.  
• All portable generators to be fitted with spark arrestors on exhaust system. |
| Construction | Torches or field welding equipment | • Immediate surrounding area would be wetted with water sprayer.  
• Fire suppression equipment to be present at location of welder/torch activity. |
| Construction and Operation | Electrical arcing | • Electrical designs and construction specifications meet or exceed requirements of the National Electric Code and National Fire Protection Agency. |
Prepare in advance to reduce the potential for traffic accidents. Mitigation for lowering the risk potential of traffic accidents includes:

- A Transportation Management Plan (TMP) that would direct and obligate the contractor to implement procedures to minimize traffic impacts would be prepared in consultation with both WSDOT and Skamania County and submitted to EFSEC for approval. The TMP would include requirements for coordination of project-related construction traffic and WSDOT planned construction projects, along with requirements for coordination of project-related construction traffic and Skamania County, City of Bingen, and City of White Salmon summer recreational traffic.

- The Applicant and its contractors would be required to comply with State and County permitting requirements for over-size and over-weight vehicles.

- The Applicant would be required to notify land owners in the Project vicinity prior to construction of transportation routes that would be used for construction equipment and labor.

- Approved State and/or County advanced warning construction signs would be placed prior to and during construction.

- Certified flaggers would be used when necessary to direct traffic when over-size and over-weight trucks either enter or exit public roads, to minimize risk of accidents.

- Pilot cars would be used both in front of and behind all trucks transporting over-size or over-weight loads on all public roadways.

- Traffic flow would not be restricted for more than 20 minutes during the construction phase.

- All loads over 10 feet wide traveling on SR 14 from east of the proposed Project Area between MP 76.77 and 76.91 would require three pilot cars, two in front and one in the rear. The two front pilot cars would be required to maintain a minimum 500-foot separation. The lead pilot car in front of the load would warn oncoming traffic of the over-size load, and the pilot car immediately in front of the over-size load would be responsible to stop all oncoming traffic.

### 3.6.4 UNAVOIDABLE ADVERSE IMPACTS

Unavoidable adverse impacts to public health are anticipated to be minimal.

Because there would be no need to transport, store, or combust fuel to generate power, the risk of unintentional or accidental fire or explosion or discharge to the environment during both construction and operations would be minimal. The risk of accident during construction would be no higher than for any large construction Project and would be minimized through standard construction safety requirements and procedures. The risk of accident during operation would be minimal.

3.7 NOISE

This section describes the existing noise levels in the vicinity of the Project and the potential noise impacts from construction and operation of the proposed Project.

3.7.1 AFFECTED ENVIRONMENT

3.7.1.1 Analysis of Environmental Noise

Noise is generally defined as loud, unpleasant, unexpected, or undesired sound that is typically associated with human activity and that interferes with or disrupts normal activities. Although exposure to high noise levels has been demonstrated to cause hearing loss, the principal human response to environmental noise is annoyance. The response of individuals to similar noise events is diverse and influenced by the type of noise, the perceived importance of the noise and its appropriateness in the setting, the time of day and the type of activity during which the noise occurs, and the sensitivity of the individual.

Sound is a physical phenomenon consisting of minute vibrations that travel through a medium, such as air, and are sensed by the human ear. Sound is generally characterized by several
variables, including frequency and intensity. Frequency describes the pitch of the sound and is measured in Hz, while intensity describes the sound’s loudness and is measured in decibels (dB). Decibels are measured using a logarithmic scale. A sound level of 0 dB is approximately the threshold of human hearing and is barely audible under extremely quiet listening conditions. Normal speech has a sound level of approximately 60 dB. Sound levels above approximately 110 dB begin to be felt inside the human ear as discomfort and eventually pain at 120 dB and higher levels. The minimum change in the sound level of individual events that an average human ear can detect is about 1 to 2 dB. A 3 to 5 dB change is readily perceived. A change in sound level of about 10 dB is usually perceived by the average person as a doubling (or if minus 10 dB, halving) of the sound’s loudness.

Due to the logarithmic nature of the decibel unit, sound levels cannot be added or subtracted directly and are somewhat cumbersome to handle mathematically; however, some simple rules are useful in dealing with sound levels. First, if the intensity of a sound is doubled, the sound level increases by 3 dB, regardless of the initial sound level. For example: 60 dB + 60 dB = 63 dB, and 80 dB + 80 dB = 83 dB.

Sound level is usually expressed by reference to a known standard. This report refers to sound pressure level (SPL). In expressing sound pressure on a logarithmic scale, the sound pressure is compared to a reference value of 20 micropascals (µPa). SPL depends not only on the acoustic power of the source, but also on the distance from the source and on the acoustic characteristics of the space surrounding the source, the receiver, and the path between them. A sound power level, on the other hand, is analogous to the wattage of a light bulb: it describes a source’s rate of emitted acoustical energy and is not distance dependent. Using the same light analogy, SPL would be the brightness or intensity of light that can be measured at a specific distance from a source. To clarify the distinction between sound power level and SPL, the latter should always be specified with a location or distance from the noise source.

The distance value associated with SPL is an important metric, as the decrease in measurable sound level due to increasing distance from any single sound source normally follows the inverse square law. In other words, SPL changes in inverse proportion to the square of the distance from the sound source. As a general rule, at distances greater than 50 feet from a noise generator such as a wind turbine, SPL drops at a rate of 6 dB with each doubling of distance. Additionally, some sound energy is absorbed in the medium (e.g., air) through which it travels as a function of temperature, humidity, and the frequency of the sound. This attenuation can be up to 2 dB over 1,000 feet. The overall sound propagation drop-off rate would vary based on other conditions such as natural terrain and intervening obstructions.

Sound frequency (Hz) is a measure of how many times each second the crest of a sound pressure wave passes a fixed point. For example, when a drummer beats a drum, the skin of the drum vibrates a number of times per second. When the drum skin vibrates 100 times per second it generates a sound pressure wave that is oscillating at 100 Hz, and this pressure oscillation is perceived—by way of the inner ear organs and their connection to the brain—as a tonal pitch of 100 Hz. Sound frequencies between 20 and 20,000 Hz are within the range of sensitivity of the best human ear.
Sound from a tuning fork contains a single frequency (a pure tone), but most sounds one hears in the environment do not consist of a single frequency but rather a broad band of frequencies differing in sound level. The method commonly used to quantify environmental sounds consists of evaluating frequencies of sound according to a weighting system that reflects human hearing sensitivity: less sensitive at low frequencies and extremely high frequencies than at the mid-range (e.g., speech) frequencies. This is called “A-weighting,” and the measured decibel level adjusted by the A-weighting constants is called the A-weighted sound level (dBA). In practice, the level of a noise source is conveniently measured using a sound level meter that includes a filter corresponding to the dBA curve of adjustment constants across the audible spectrum.

C-weighting is another type of filter, with adjustments that help expose low-frequency sound sources that the ear does not detect well, such as compressors, pumps, and diesel engines. For the same measured sound, it is not uncommon for corresponding dBC and dBA levels to vary. As an example, the difference between dBC and dBA levels within an office building may be 20 dB (i.e., 40 dBA and 60 dBC). These wind turbines are not a source of substantial low-frequency noise. Because low frequency sound is less audible to human hearing, C-weighting is often used to assess potential annoyance from rattling due to low frequency noise that may excite vibration in structures.

Although the dBA may adequately indicate the level of environmental noise at any instant in time, community noise levels vary continuously. Most environmental noise includes a mixture of noise from distant sources that creates a relatively steady background noise in which no particular source is identifiable. A single descriptor called the equivalent sound level \( L_{eq} \) may be used to describe sound that is changing in level. \( L_{eq} \) is the energy-mean dBA during a measured time interval. It is the “equivalent” constant sound level that would have to be produced by a given source to equal the acoustic energy contained in the fluctuating sound level measured. In addition to the energy-average level, it is often desirable to know the acoustic range of the noise source being measured. This is accomplished through the maximum \( L_{eq} \) \( (L_{max}) \) and minimum \( L_{eq} \) \( (L_{min}) \) indicators that represent the root-mean-square maximum and minimum noise levels measured during the monitoring interval. The \( L_{min} \) value obtained for a particular monitoring location is often called the acoustic floor for that location.

To describe the time-varying character of environmental noise, the statistical noise descriptors \( L_{10}, L_{50}, \) and \( L_{90} \) are commonly used. They are the noise levels equaled or exceeded 10 percent, 50 percent, and 90 percent of the measured time interval, respectively. Sound levels associated with \( L_{10} \) typically describe transient or short-term events. For the \( L_{50} \) descriptor, half of the sounds during the measurement interval are softer than \( L_{50} \) and half are louder. Levels associated with \( L_{90} \) often describe background noise conditions and/or sound sources that exhibit continuous, “steady-state” characteristics.

Finally, another sound descriptor known as the day-night average sound level (Ldn) represents the average sound level for a 24-hour day and is calculated by adding a 10 dB penalty only to sound levels during the night period (10:00 PM to 7:00 AM). The \( L_{dn} \) is typically used to define acceptable land use compatibility with respect to noise. Because of the night-time penalty associated with the \( L_{dn} \) descriptor, the \( L_{eq} \) for a continuously operating sound source during a 24-hour period would be numerically less than the day-night level. Thus, and by way of example,
for a power plant operating continuously for periods of 24 hours, the $L_{eq}$ would be 6 dB lower than the $L_{dn}$ value.

Table 3.7-1 provides sound levels of typical noise sources and environments to provide a frame of reference.

Aside from industrial and other settings where workers may be exposed to very high noise levels and the risk of hearing loss, environmental noise effects are typically limited to subjective impacts (e.g., annoyance, nuisance, dissatisfaction) and activity interference (i.e., impacts to sleep, speech, and learning). Despite attempts by prominent acousticians to satisfactorily quantify the association between measurable sound levels and corresponding reactions of annoyance and dissatisfaction, there is no way to measure the subjective impacts of noise. Further, the aforementioned variability of individual human sensitivity and/or tolerance to noise defies creation of a common standard.

### 3.7.1.2 Regulatory Overview

**Washington State and Skamania County Noise Limits**

WAC 463-62-030 states that energy facilities shall meet the noise standards established in Chapter 70.107 RCW, also known, in short, as the “Noise Control Act of 1974”, as implemented in the requirements of WAC 173-60. SCC Title 8 Chapter 22: Noise Regulations identifies limits and exceptions specific to noise in Skamania County. SCC 8.22 was adopted pursuant to, and is consistent with, WAC 173-60. Environmental designations for noise abatement (EDNA) are established in SCC Section 8.22.080 and WAC 173-60-030. These rules establish maximum permissible environmental noise levels and are based on the EDNA, which is defined as an area or zone (environment) within which maximum permissible noise levels are established. There are three EDNA classes:

- **Class A.** Lands where people reside and sleep (such as residential);
- **Class B.** Lands requiring protection against noise interference with speech (such as commercial/recreational);
- **Class C.** Lands where economic activities are of such a nature that higher noise levels are anticipated (such as industrial/agricultural).

The noise limits that a new source can impose for each land use classification are presented in Table 3.7-2.

Source: URS internal information and Table N-2136.2 on p. 18 of the Technical Noise Supplement (Caltrans 1998).
The Project is sited on land zoned as Forest Land 20 (FL 20) and Unmapped (UNM) zones. Approximately 0.9 mile west of the Project Area, the alternative Operations and Maintenance facility site would be located in the R-5 zone. Both the Project Area and the alternative Operations and Maintenance facility site are used for commercial timber harvest. Based on current zoning and land use, a reasonable interpretation would classify the Project Area as a noise source having an environmental designation of Class C EDNA, and the alternative Operations and Maintenance site as having an environmental designation of Class A EDNA. With respect to the receiving land uses, this noise analysis has identified some receiver locations being within agriculturally zoned lands that could normally be classified as Class C EDNA. Since the WAC does not specifically address the situation of an occupied residential structure located on an agricultural parcel, one might assess the residence as Class A EDNA and the outlying property line as Class C EDNA. EFSEC has accepted such an interpretation for other wind energy projects such as Wild Horse and Kittitas Valley, the latter of which had approval upheld by the Washington Supreme Court. While other interpretations may be feasible, Table 3.7-3 illustrates the Class A (Residential) receiver noise level limitations for noise generated from a Class C (Commercial) EDNA (SCC 8.88.090, 100) source, including adjustments based on the duration of noise exposure time.

Levels shown are at the property line of the receiving property and indicative of a source that is located in a Class C EDNA.

Notwithstanding the above and per 173-60-050 WAC, there are exemptions to the limits for certain noise-producing activities or source types as follows:
• Construction noise (including blasting) between the hours of 7 AM and 10 PM;

• Motor vehicles when regulated by 173-62 WAC (“Motor Vehicle Noise Performance Standards” for vehicles operated on public highways);

• Motor vehicles operated off public highways, except when such noise affects residential receivers; and

• Noise from electrical substations (WAC 173-60-050[2][a]).

Despite these exemptions, 173-60-50(6) WAC states, “Nothing in these exemptions is intended to preclude the Department from requiring installation of the best available noise abatement technology consistent with economic feasibility.”

**US Environmental Protection Agency and Occupational Safety and Health Administration**

While the US Environmental Protection Agency (EPA) has no regulations governing environmental noise, the EPA has conducted extensive studies to identify the effects of certain sound levels on public health and welfare. An EPA document (USEPA 1974) identifies sound levels “requisite to protect the public health and welfare with an adequate margin of safety.” The EPA specifies a day-night sound level ($L_{dn}$) of 55 dBA for outdoor areas, where quiet is a basis for use. The $L_{dn}$ is similar to the 24-hour $L_{eq}$ except that a 10-decibel penalty is added to sound levels between 10 PM and 7 AM to account for sleep interference. For a potentially continuous source of noise such as operation of the Project, the 55 dBA $L_{dn}$ effectively translates to a 49 dBA hourly $L_{eq}$, which is generally consistent with the 50 dBA $L_{eq(1)}$ required by Skamania County and the State of Washington. However, this EPA finding is guidance, not regulation.

The EPA’s 49–50 dBA $L_{eq(1)}$ sound level is far less than what is usually associated with hearing loss. The federal Occupational Safety and Health Administration (OSHA) has developed noise standards designed to address worker health and safety risks associated with noise exposure and the potential for noise-induced hearing loss. The action level under these OSHA standards is an 8-hour time-weighted average of 85 dBA. Exposure to sound in excess of this standard requires the employer to initiate a hearing conservation program to evaluate the exposure, its duration, possible engineering controls to reduce noise and the provision of hearing protection to employees. The decibel levels covered by the state standards in WAC 173-60-110 are well below OSHA hearing impact standards.

**Low Frequency Noise**

Low frequency sound typically ranges from 100 Hz to 20 Hz, the latter of which is the generally understood limit audible to the human ear. WAC 173-60-110 uses the A-weighting scale because it is a standard that characterizes sound frequencies that are more sensitive to the human ear. Local jurisdictions within the State of Washington that have a C-weighted scale standard do not apply it to wind turbines. There is no Washington State standard associated with the C-weighted scale for low-frequency noise because the C-weighted scale is primarily used as an indicator of low frequency induced noise vibrations.
3.7.1.3 Affected Environment

Noise Receivers

Although Figure 3.7-1 shows that there are many potential noise-sensitive receivers surrounding the Project vicinity, the three receivers closest to the Project wind turbine tower locations are the two closest residences, which are approximately 0.48 mile (2,560 feet) southeast of Tower A1 (R1 on Figure 3.7-1) and 0.8 mile (4,265 feet) southwest of Tower B16 (R2 on Figure 3.7-1). A potential future residence (R3 on Figure 3.7-1) is approximately 0.38 mile (2,000 feet) from Tower A1.

Existing Sound Levels

While some reference materials such as the Federal Transit Administration’s *Transit Noise and Vibration Impact Assessment Guide* (FTA 2006) offer techniques to make a coarse estimate of existing noise levels for an area based on parameters such as population density, the reality is that at residences in or near any project proposed for development, there is no such single and consistent background noise level. The background noise level can vary at a given location or across different locations on a Project Area due to factors such as changing climate conditions and the presence of contributing noise sources (including flows of water associated with creeks or canals, agricultural equipment operations, irrigation pumps and equipment, livestock, road, rail and air traffic, wildlife such as birds or insects, dogs, and routine human activities). Hence, a field survey that includes documentation of observed or perceived noise events and monitoring of ambient sound at different times of day at different locations helps to accurately depict actual conditions that influence pre-project ambient sound level. These conditions and their influence on ambient sound level offer clues as to how the increase in noise level resulting from the operation of any project, including those that emit a constant level, would likely vary with location and time of day.

To help establish representative baseline ambient sound levels for the Project vicinity and characterize the existing noise environment in the areas occupied by the receivers shown in Figure 3.7-1, a set of long and short-term sound level measurements were conducted from January 20 to 22, 2009. The locations of the short-term and long-term measurement sites were selected to approximate the existing ambient sound in the vicinity of Ausplund Road (and hence, Receiver 1). Likewise, the location of ST2 was chosen to generally represent the ambient sound level for the Mill A community and its surroundings west of the Project, on which Receiver 2 is located.
The measurement locations included a position near the intersection of Ausplund Road and Kollack-Knapp Road (ST1), and a position near the intersection of Jessup Road and Manzanola Road (ST2). For purposes of the impact analysis described in this document, these measurement locations are considered reasonably representative for each general area, and more specifically R1 and R2, respectively, on the basis of similar expected ambient sound sources, despite the dissimilarity of locations. For instance, the ambient sound environment measured at ST1 likely contains the same typically identifiable sound components (e.g., distant bird song, dog barks, roadway traffic) and a generally unidentifiable “background” that one might measure at the precise geographic location of R1.

A Bruel+Kjaer 2250 (SN: 2653963) ANSI Type-1 real-time sound analyzer, fitted with a standard microphone windscreen and mounted on a five-foot tall tripod, was used for the short-term measurements. The instrument was field calibrated before and after each measurement period with an acoustic calibrator. All sound level measurements were performed in accordance with International Organization for Standardization guidelines (ISO 1996a, b, and c). Weather conditions during the survey period were seasonably cold with overcast skies, but there was no precipitation during the measurement periods. The air temperature varied from 30 to 44 degrees Fahrenheit, with 33 to 53 percent relative humidity. Measured ground wind speeds in the vicinity of the measurement positions were low, with averages ranging from 0 to 1 mph, and directed toward the north for all measurements. Detailed weather conditions for individual noise measurements and a summary of the short-term measurement data are included in Table 3.7-4.

A long-term measurement (LT1) was conducted at a position near the corner of Ausplund Road and Kollok-Knapp Road using a Larson Davis 720 (SN: 0436) ANSI Type 2 Integrating sound level meter. With only the windscreen-covered microphone exposed to the outdoor environment, the sound level meter was placed in a locked, weather-resistant case and secured to a nearby tree. The long-term measurement consisted of consecutive 15 or 30 minute averages conducted over an uninterrupted 24-hour period. The instrument was field calibrated before and after the measurement period with an acoustic calibrator (CAL 200 s/n: 5789). Data from the long-term measurement is presented in Table 3.7-5.

Field observations associated with the short and long-term measurements are as follows:

**ST1.** This measurement location was at the corner of Ausplund Road and Kollok-Knapp Road. There are several residential receivers located in this general area. The first short-term measurement at this location was conducted between 11:52 AM and 12:12 PM on January 21, 2009. The first measurement noise sources included distant aircraft, distant roadway traffic, dogs barking in the distance, and birds vocalizing. The second short-term measurement was conducted between 6:00 PM and 6:20 PM on January 21, 2009. The second measurement noise sources included distant aircraft, distant roadway traffic, and dogs barking in the distance. The third short-term measurement at this location was conducted between 11:32 PM and 11:52 PM on January 21, 2009. Noise sources during the third measurement included distant roadway traffic and dogs barking in the distance. The first measurement $L_{eq}$ one-minute interval values ranged from 34 to 59 dBA, the second measurement 1-minute $L_{eq}$ values ranged from 27 to 66 dBA, and the third measurement 1-minute $L_{eq}$ values ranged from 25 to 49 dBA. $L_{eq}$ for the entire duration of each of these three measurement periods appears in Table 3.7-4.
ST2. This measurement location was in front of the John Schwab Memorial Tennis Courts on the corner of Jessup Road and Manzanola Road. The sound level meter was approximately 15 feet from Jessup Road. The first short-term measurement at this location was conducted between 12:48 PM and 1:08 PM on January 21, 2009. The first measurement noise sources included distant aircraft, distant roadway traffic, children playing in the distance, and birds vocalizing. The second short-term measurement was conducted between 6:36 PM and 6:56 PM on January 21, 2009. The noise sources for the second short-term measurement included distant aircraft and distant roadway traffic. The third short-term measurement was conducted between 12:08 AM and 12:28 AM on January 22, 2009. Noise sources present during the third short-term measurement included distant roadway traffic. The first measurement $L_{eq}$ one-minute values ranged from 35 to 52 dBA, the second measurement 1-minute $L_{eq}$ values ranged from 34 to 54 dBA, and the third measurement 1-minute $L_{eq}$ values ranged from 31 to 39 dBA. $L_{eq}$ for the entire duration of each of these three measurement periods appears in Table 3.7-4.

LT1. This measurement location was at the corner of Ausplund Road and Kollock-Knapp Road, on the north side of the roadway. The sound level meter was placed in a locked, weather-resistant case and secured to a tree near the side of the road. The windscreen-covered microphone, connected to the meter by cable, was attached to the tree trunk at approximately 3 to 4 feet above the ground. Concurrent with these short and long-term ambient sound measurements, Applicant meteorological stations 320, 321, and 323 collected data on wind speed, direction, and temperature at various elevations above grade. Average reported wind velocities from the station NRG Type 40 anemometers were quite low, and while apparently consistent with the low average wind velocities measured on the ground at the sound measurement positions, were considered potentially compromised by icy conditions due to the low recorded temperatures and high moisture content of the air.

Table 3.7-4 shows the considerable decibel differences between the Leq measurements and the adjusted values when intervals containing documented automotive pass-by events were removed from the short-term measurement data sets (i.e., “without cars”). This change is unsurprising due to the proximity of the real-time sound analyzer to the roadway at ST1 and ST2. Upon removing these intervals, the remaining collected data more accurately depicts the background or a measurement position that is considerably distant from passing road traffic.

Table 3.7-6 presents the arithmetic average Leq of ST1 and LT1.

3.7.2 IMPACTS

3.7.2.1 Methodology

Construction

Project construction would take place over a period of 12 months between the hours of 7:00 AM and 7:00 PM Monday through Friday. During construction activities, a varying number of construction equipment and personnel would occupy the Project Area, which would result in varying levels of construction noise. The Project would use conventional construction techniques and equipment, including excavators, bulldozers, heavy trucks (e.g., water truck, dump truck), and similar heavy construction equipment. Specialized construction equipment for logging, foundation building and other tasks using special equipment (e.g., heavy duty cranes) may be needed.

Conventional construction activities would result in a short-term temporary increase in the ambient noise level resulting from the operation of construction equipment. The increase in noise level would be experienced primarily close to the noise source. The magnitude of the noise effects would depend on the type of construction activity, noise level generated by construction equipment, duration of the construction phase(s), and the distance between the noise source and receiver.

Construction noise impacts associated with the Project were assessed with spreadsheet-based noise calculations. User inputs include:

- Distance from source—the distance between the edge of the construction site and the considered receiver.
- Duty cycle—the portion of an hour, in aggregate, that a piece of equipment is energized (stationary or mobile) and creating noise.
- Quantity—the number of equipment pieces or noise-producing events over a specific time period (e.g., equipment utilization per month).
- Hours—the number of daytime hours (up to 12) that represent a typical daily work shift.

These inputs allow sound propagation prediction using the following formula:

\[ L_{eq} = \text{Source SPL} + 10 \times \log_{10} (\text{Duty Cycle}) + 10 \times \log_{10} (\text{Quantity}) + 10 \times \log_{10} (\text{Hours/12}) - 20 \times \log_{10} (\text{Distance from Source} / \text{Reference Distance}) \]

where source SPL and reference distance describe the typical noise, associated with a single piece of equipment, measured at a pre-defined distance. For instance, a chainsaw may have a source SPL of 78 dBA measured at a distance of 50 feet from its operator. Values for source SPL and reference distance have either been reproduced from available manufacturers’ data or calculated from industry-accepted formulas linking sound generation to the rated engine.
horsepower of the equipment. Note that for purposes of model conservatism, air and ground absorption effects are not included.

**Operation**

Once the Project is commissioned and operating normally, the new ambient sound level that can be perceived would be a logarithmic sum of background and Project noise. For a wind project, and aside from non-dominant sources such as electrical substations, operation noise level varies with wind speed at the turbines. When available winds are relatively calm, the turbines emit very little noise compared to what occurs when stronger wind conditions have turbines operating at their highest power generation and, concurrently, highest noise levels. Thus, a wind project’s noise level at a particular receptor is primarily determined by the wind speed occurring at the turbine and the distance to the closest turbines.

The Cadna/A® Noise Prediction Model (Version 3.71.125) was used to estimate the project-generated sound pressure levels at the property lines and noise-sensitive receivers. Cadna/A® is a Windows® based software program that predicts and assesses noise levels near industrial noise sources based on International Organization for Standardization (ISO) 9613-2 standards for noise propagation calculations. Routinely used by acoustical professionals to develop sound level predictions from a variety of complex industrial sources, including wind turbines, the model uses these industry-accepted propagation algorithms and accepts sound power levels (in dB re: 1 picowatt) for the nine standard octave bands ranging from 31.5 Hz to 8,000 Hz, as typically provided by the equipment manufacturer and other sources. A comparison of overall reference sound power level (Lw, dBA) for a variety of different manufactures and models, with the power capacity being the primary differentiator is presented in Table 3.7-7. The calculations account for classical sound wave divergence, plus attenuation factors resulting from air absorption, basic ground effects, and barrier/shielding. Intervening natural and man-made topographical barrier effects were considered as appropriate, including those from structures such as major buildings, tanks, and large equipment.

Table 3.7-8 summarizes octave band sound power level inputs from each type of pre-defined noise source. Given that the exact turbine model to be used for the Project has not yet been determined at the time of this report, conservative but realistic and representative values for the type of equipment being considered for this Project have been used. For example, the model currently uses data from an industry leading 1.8 MW 50/60 Hz wind turbine, at wind speeds of about six meters per second and nine meters per second at 33 feet (10 meters), in accordance with the protocol established in International Electrotechnical Commission Standard 61400-11:200216. The decibel values shown for the two wind turbine generator wind speeds in Table 3.7-8 at each octave band center frequency include a +2 dB margin, which produces an A-

\[16 \text{ As noted, the modeling is based using conservative and representative values for the type of equipment being considered. The noise model currently uses data from an industry leading 1.8 MW 50/60 Hz wind turbine. The project may use larger wind turbines, up to 2.5 MW, and these could have a different noise profile. However, total project noise would be limited by the 75 MW EFSEC certification. If 1.8 MW turbines were selected, the project could use up to 42 turbines, however if 2.5 MW turbines were selected, only 30 turbines could be built, and overall project noise could be lower.} \]
weighted overall level that represents the top end of a range associated with the manufacturer’s warranty values.

The Project layout configuration (i.e., the arrangement of wind turbine generators and ancillary equipment on the site) was imported into Cadna/A® from Project files provided by the client. The Cadna/A model consequently predicts hourly sound levels, which would be equal at all times of the day in this case. The formula used to derive the overall SPL (in dBA) from sound power level (PWL) is as follows:

\[ \text{SPL} = \text{PWL} - 20 \log(r) - 10.9 + C \]

where \( r \) is in meters and \( C \) is a dimensionless absorption constant (Harris 1998).

At each studied receptor, the model calculates the acoustical contribution from each input source, which in this exercise using Cadna/A includes all expected wind turbines associated with the Project at locations depicted in Figure 3.7-1. When Project micrositing occurs and final turbine layout and turbine model are arrived at, additional noise modeling can be performed to re-predict operation noise level and re-evaluate anticipated project compliance with the standards discussed in this EIS.

3.7.2.2 Proposed Action

General Construction Noise

Table 3.7-9 shows the predicted construction noise levels experienced at the closest residences to the Project. As per 173-60-050 WAC, construction noise between the hours of 7:00 AM and 10:00 PM are exempt from the receiver noise limit guidelines. Consequently, the calculated values at the three closest receivers comply with the applicable noise standard.

</tbody>
</table>

If it is determined to be necessary, blasting would occur during the turbine foundation portion of the construction schedule and only during daytime hours. Blasting noise could possibly be audible at a considerable distance from the construction site and noticeable at residences near the Project Area. Sound levels from blasting at a receiver would not be extreme, however, and the occurrence would be low in frequency, intermittent, and confined to a period of one to two months. The WAC 173.60.050 exemption for temporary construction noise includes noise from blasting activity, from the aforesaid state noise limits between the hours of 7 AM and 10 PM.
The large distances between much of the Project Area and potentially affected residences, the temporary nature of construction, and the restriction of construction activities to daytime hours would serve to minimize potential noise impacts from construction activities. Based on the anticipated noise levels and the timing aspects of these impacts, construction noise impacts are expected to be low.

If Project construction occurred in phases, the effect on the level of noise impacts would be to extend the total duration of temporary disturbance from Project construction, but to reduce the intensity or magnitude of impacts for any individual phase. Construction noise impacts would still be temporary, localized, and low in magnitude, and overall Project impacts during construction would remain low in a phased-construction scenario.

**General Operation Noise**

The predicted operational noise levels at the three closest residences to the Project are supplied in Tables 3.7-10 and 3.7-11. This analysis evaluates the existing noise levels at the closest receptors, and evaluates increases in dBA at these locations. The Washington noise regulations do not require this information; however, the Applicant supplied this information to fully inform EFSEC during the Application for Site Certificate process. Table 3.7-12 shows the results of a refined predictive noise analyses using the same Cadna/A modeling program as used for the draft EIS, but applying or adding new parameters.

Source: URS
Under certain conditions, there is the potential for one or more of the following phenomena to occur that may temporarily cause a variance in the predicted sound levels:

- In the Cadna/A prediction model, all studied wind turbine generators were assumed to operate at the same speed. In reality, very slight differences in operating rotor speeds due to non-uniformities in the passing wind profile can result in intermittent constructive and destructive interference—or what one might call “beats,” that can have a perceptible frequency as current research suggests (van den Berg 2006).

- The atmosphere can either be “stable” or “unstable,” which in summary are descriptors for how layers of air mass interact. The latter of these two is usually associated with cold air near the ground that is not well coupled to higher air masses. This effect can explain why high wind speeds at wind turbine generator hub height can be substantially greater than those near ground level (van den Berg 2006).

- The relative humidity and ambient temperature have a substantial effect on the attenuation of outdoor sound at high frequencies and long distances through air absorption. Relative humidity and temperature effects can produce a variance of approximately +/- 2 dBA.

- The uncertainty range for the PWL of each wind turbine generator is +/- 2 dBA.

- Due to the very low ground wind speeds recorded during the short-term measurements, actual ambient noise levels at any receiver in the Project vicinity may be higher as a result of noise generated by turbulence from wind streaming through vegetative ground cover (i.e., trees and grasses). Further, since wind-generated noise tends to rise at a rate of 2.5 dBA per 1 m/s increase in wind speed, and generally turbine aerodynamic noise rises at a rate of only 1 dBA per 1 m/s increase in wind speed, high wind speeds near the ground may cause background sound (i.e., not Project operation) to dominate the perceptible and even measurable ambient sound environment (BLM 2005).

Because predicted Project operation sound pressure levels at the nearest noise-sensitive receivers are at least 7 dBA lower than the 50 dBA $L_{eq}$ compliance threshold, none of these above conditions is expected to result in the Project operation exceeding noise regulations.

**Low Frequency Sound**

Low frequency noise produced by a wind turbine generator can include tonal components produced by the generator and gearbox within the nacelle downstream of the rotor hub, atop the tower mast. The source sound power levels in Table 3.7-8 already include these noise contributors. Modern wind turbine design typically includes sound attenuation features in the nacelle to help reduce the magnitude of these electro-mechanical noise components to the aggregate, so that the spectrum of sound levels at the octave band center frequencies shown in Table 3.7-8 largely describes the aerodynamic effects of the rotor blades interacting with the passing wind profile. Even though there are no relevant regulations and standards related to dBC, the turbine sound power level manufacturer ratings show that C-weighted levels are within
2 dB of A-weighted levels. Therefore, low frequency noise is not anticipated to be an issue for this Project.

In earlier generations of wind turbine design, the practice of using downwind rotors allowed turbulence from the tower mast to disrupt favorable aerodynamic conditions for the passing blades, causing considerable low frequency noise. This practice has been abandoned by the contemporary upwind rotor design of virtually all wind turbine generators built in the past five years, including the models contemplated for this Project.

The noise produced by air interaction with the rotor blades tends to be broadband noise, but is amplitude-modulated as the upstream blades pass the tower, resulting in what some call a characteristic “swoosh.” The blade passage frequency of this “swoosh” is only a temporal modulation of sound and should not be confused with low frequency sounds. Research studies of low-frequency noise emissions from wind turbines have determined that low frequency noise is a function of the wind itself, and that the “swoosh” of the turbines is actually in the readily audible range of frequencies (500 to 1 kiloHertz) (Leventhall 2006). Virtually any sound can be time-modulated without changing its pitch. Thus, low frequency modulation of audible sound does not imply the presence of actual low frequency sound or infrasound, which is discussed in the following subsection.

Table 3.7-13 shows differences in dBA and dBC predicted at the three representative receivers R1, R2, and R3 rather than at the source (the wind turbines). Information regarding potential impacts from exposure to low frequency noise is inconclusive. Scientific articles suggest that low frequency noise does not pose a health risk (Leventhall 2006). There may, however, be some correlation between an individual receptor’s psychological sensitivity to the noise source (like or dislike for the noise source) and complaints regarding discomfort from that noise source. These are sometimes associated with complaints regarding sleep disturbance. Figure 3.7-2 illustrates the thresholds of human hearing at low frequencies. Because sensitivity to noise can be influenced by such psychological factors and can subjectively be deemed significant by an affected individual, regardless of measurable frequency or amplitude level, it is difficult to quantify these impacts or to impose mitigation. However, modern turbine designs have been modified to reduce or eliminate low frequency sound.17

Source: URS
Infrasound

The term infrasound describes sound with frequencies of 20 Hz or less that are generally considered below the threshold of human hearing. Such sound, if sufficiently high in magnitude, can still be perceived or even heard as induced by vibration. Natural sources of infrasound include waves, thunder, wind, and even certain species of wildlife.

A review of wind turbine noise measurement studies conducted by Jakobsen (2005) concluded that operation of contemporary wind turbine generators featuring rotors “upwind” of tubular tower masts generated infrasound in the range of 70 G-weighted decibels (dBG) at a distance of one hundred meters. (The G-weighting scale, like the oft-used A-weighting scale for audible sound spectra, is a filter applied to low-frequency sound as described in ISO 7196:1995E.) Jakobsen also notes that this infrasound, usually associated with aerodynamic effects of blade passage past the tower mast, tends to ignore atmospheric sound absorption and ground attenuating effects due its very large wavelength. Hence, one could reasonably expect infrasound to attenuate only with increasing propagation distance.

Recent studies performed for the Canadian Wind Energy Association have described usage of 85–90 dBG as a criterion for human perception of infrasound and, by reasonable extension, the likely threshold for infrasound complaint (HGC Engineering 2006).
The horizontal distances of the Project wind turbines to the nearest noise-sensitive receivers are at least 615 meters, which provides sufficient attenuation to offset the amount of decibels that one might add to account for the quantity of wind turbines of the Project. Thus, the expected infrasound at the nearest existing receivers (i.e., R1 and R2) would remain under an estimated value of 70 dBG, which is 15 dBG less than the previously stated criteria. This estimated Project aggregate wind turbine generator infrasound level also is far below what NASA studies determined (125 dB, linear) as a threshold for potential health impacts (HGC Engineering 2006).

**Project Decommissioning**

In compliance with WAC 463-72 Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. A detailed site restoration plan is required within ninety days of Project decommissioning. The initial site restoration plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is suspended or terminated during construction or before it has completed its useful operating life. The initial site restoration plan would include or parallel a decommissioning plan for the Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major noise issues presently anticipated, including noise impacts from construction activities related to removal of the wind generation equipment and site restoration. If impacts to noise are anticipated to occur as a result of site restoration and Project decommissioning, mitigation measures would be proposed as part of the plan.

**3.7.2.3 No Action Alternative**

Under the No Action Alternative, the proposed Project would not be constructed. Existing sound levels would be expected to remain largely the same. Although the generally quiet ambient noise levels in the Project Area would continue, occasionally elevated noise levels in the immediate Project vicinity would be expected from ongoing timber harvest activities at the Project Area.

**3.7.3 MITIGATION**

The following mitigation measures are identified to avoid, minimize, and compensate for potential noise-related impacts during construction and operation of the proposed Project to the extent feasible.

- Equip all noise-producing Project equipment and vehicles using internal combustion engines with mufflers, air-inlet silencers where appropriate, and any other shrouds, shields, or other noise-reducing features in good operating condition that meet or exceed original factory specification. Mobile or fixed “package” equipment (e.g., arc-welders, air compressors) would be equipped with shrouds and noise control features that are readily available for that type of equipment.
- Regulate all mobile or fixed noise-producing equipment used on the Project for noise output governed by local, state, or federal agency regulations, to comply with such regulations while in the course of Project activity.

- Designate that the use of noise-producing signals, including horns, whistles, electronic alarms, sirens, and bells, would be for safety warning purposes only. Unless required for such safety purposes, and as allowable by applicable regulations, no construction-related public address, loudspeaker, or music system would be audible at any adjacent noise-sensitive land use.

- Implement a noise complaint process and hotline number for the surrounding community. The Applicant would have the responsibility and authority to receive and resolve noise complaints.

### 3.7.4 UNAVOIDABLE ADVERSE IMPACTS

Construction noise is exempt so long as it occurs during daytime hours, and operation noise is predicted to be less than the nighttime threshold of 50 dBA $L_{eq}$ per Washington State and Skamania County regulations.

The analysis of noise impacts presented here was based on specific design features of the proposed Project that were current as of the date of this Draft EIS. These features, such as the turbine manufacturer and model selection, the layout of the turbines in the Project Area and their corresponding distances to identified closest noise-sensitive receivers, can greatly influence the analysis results. However, assuming that final turbine selections and siting locations are comparable to those features used in this analysis, no substantial adverse construction or operation noise impacts are anticipated for the Project.

### 3.7.5 REFERENCES

### 3.8 LAND USE AND RECREATION

This section describes the existing land uses and recreation areas at the Project Area and in surrounding areas, and identifies potentially applicable land use policies and zoning ordinances. This section also discusses potential Project impacts on land use and recreation, as well as the consistency of the proposed Project with local land use plans and zoning ordinances.

#### 3.8.1 AFFECTED ENVIRONMENT

#### 3.8.1.1 Existing Land Use

**Project Area**

The Project Area is located in an unincorporated portion of southeastern Skamania County, Washington, about two miles north of the Columbia River (see Figure 1-1). The primary use at the Project Area is commercial forestry. The site has been used for this purpose for the last century. During this time, the owners and operators have logged the property over a series of approximately 50-year logging rotations. Ongoing tree farming activities include regular clearing, replanting, and harvesting.
Portions of the Project Area are also used for utility corridors. A natural gas pipeline, owned and operated by Williams Gas, runs from east to west across the Project Area near the north boundary of the site. Two existing transmission line corridors also cross the Project. These approximately 250-foot wide corridors, which generally run in an east-to-west direction, are owned and maintained by BPA. Each corridor is occupied by a high-voltage transmission line and its associated support towers and access roads. The corridors are routinely maintained to remove all tall growing vegetation, as well as any adjacent “danger trees” (i.e., those trees with the potential to fall into the existing lines) in order to avoid interference with these lines.

**Surrounding Areas**

Land use in the Project vicinity is predominately commercial forestry with other typical rural uses and both incorporated and unincorporated communities dispersed throughout (see Figure 3.8-1). The incorporated cities of White Salmon and Bingen, Washington are located adjacent to each other approximately 7 miles southeast of the Project Area, along the north side of the Columbia River. Directly south and across the Columbia River from Bingen is the City of Hood River, in Hood River County, Oregon. The city of Stevenson, the Skamania County seat, is located approximately 15 miles southwest of the Project Area along the Columbia River. These incorporated cities have mixed urban uses typical of small communities.

In the more immediate vicinity of the Project Area, the unincorporated community of Willard is located approximately 2.25 miles northwest of the Project Area, and the unincorporated community of Mill A is located approximately 1.5 miles west of the site. Other residential uses in the immediate vicinity of the Project Area are generally rural, low- to medium-density single-family homes between 30 and 50 years old. There are approximately 400 residences and businesses within three miles of the Project Area (see Figure 3.8-2). A new homesite location has been approved approximately 2,000 feet (0.38 mile) from the south property line of the Project Area.

Commercial forestry areas and the Gifford Pinchot National Forest are generally located to the north of the Project Area. East of the Little White Salmon River, lands are currently being used for commercial timber production under ownership by S.D.S. Co., LLC, Broughton Lumber Company, and Washington State. The Washington State lands are managed by DNR for commercial harvest to support the State’s schools.

To the south of the Project Area is the Columbia River Gorge National Scenic Area (see Figure 3.8-3). The Scenic Area extends along the Columbia River for about 85 miles and includes 292,500 acres in parts of three Oregon and three Washington counties. In addition to forested areas, land uses within the Scenic Area near the Project Area on the Washington side of the Columbia River include limited agriculture, mostly pear and apple orchards recently augmented with some wine grape vineyards. On the Oregon side of the Columbia River, land use within the Scenic Area is predominantly commercial timber production and residential. Further south of the Scenic Area in Oregon, land uses include commercial forestry, agriculture (primarily pears, apples, and cherries), and some residential.
SR 14 and the Burlington Northern Santa Fe Railway are located between the Project Area and the Columbia River, within the Scenic Area. I-84 is located on the Oregon side of the Columbia River, within the Scenic Area.

### 3.8.1.2 Recreation

The primary recreation activities within Skamania County are camping, hiking, and fishing. Major recreation locations include the Gifford Pinchot National Forest; the Mount St. Helens National Volcanic Monument; the Lewis and Clark Trail Highway, which follows the Columbia River through Skamania County; and the Columbia River Gorge National Scenic Area south of the Project Area. Informal recreational activities such as hunting, hiking, and mountain biking also take place on private land, subject to landowner approval. There are no formally designated recreational areas within the Project Area; however, the Applicant would allow informal recreational use of their land with approval.

Summer recreational activities include water sports such as fishing, swimming, boating, river rafting, kayaking, water skiing, and wind surfing; as well as camping, biking, hiking, horseback riding, hunting, picnicking, and other outdoor sports. Some of these activities continue into the winter, weather permitting. Sightseeing is a popular year-round activity in the Columbia River Gorge. Recreational facilities within approximately 25 miles of the Project Area are shown in Figure 3.8-3 and listed in Table 3.8-1.

The closest recreational facility is the Underwood Park and Community Center, located near Underwood just off of Cook-Underwood Road, approximately 1.5 miles east of the Project Area. The community center has a large gymnasium, stage, kitchen, and meeting room; while the park has soccer fields, a pavilion, and a playground. Recreational facilities or activities available closest to the Project Area include hiking and horseback riding along Buck Creek Trail, Husum Hills Golf Course, BZ Corners Boat Launch, Underwood Park/Community Center, and Drano Lake Boat Ramp.

There are no Skamania County recreation facilities within five miles of the proposed Project. However, two national trails, the Lewis and Clark National Historical Trail and the Oregon National Historic Trail, are located within 5 miles of the Project Area. These trails roughly follow SR 14 and I-84, respectively. Also within 5 miles of the site, the White Salmon River is designated as a Wild and Scenic River, and within 25 miles, the Klickitat River is also so designated.

There are no new parks or recreation facilities planned within a 5-mile radius of the site, either as part of the Skamania County Parks and Recreation Master Plan or the Columbia River Gorge National Scenic Area Management Plan. No federal recreation regulations apply to the site, nor are there federal or state plans for recreation facilities on or near the site.

3.8.2 APPLICABLE LAND USE REGULATIONS

Skamania County has two independent sets of land use regulations. The first is a stand-alone zoning code (SCC Title 22) that regulates uses and development within the General Management Area (GMA) and Special Management Area (SMA) of the Columbia River Gorge National Scenic Area. The Scenic Area Code is based on the Management Plan for the Scenic Area, which is overseen by the USFS and Columbia River Gorge Commission, as directed by the National Scenic Area Act.

The remainder of unincorporated Skamania County, as well as those portions of the Scenic Area classified as Urban Areas (such as White Salmon, Bingen, and Hood River), is governed by the Skamania County Comprehensive Plan, zoning regulations in SCC Title 21, and Titles 20, Shorelines, and 21A, Critical Areas.

Because the Project Area is located outside of the National Scenic Area, land use at the site is regulated by the Skamania County Comprehensive Plan and SCC Titles 21, 20, and 21A. In addition, although the Project Area is immediately adjacent to the National Scenic Area, the National Scenic Area Act expressly provides that land use regulations developed for the National Scenic Area do not apply to adjacent area. Section 544O(a)(10) of the Act states:

Nothing in Sections 544 to 544p of this title shall establish protective perimeters or buffer zones around the scenic area or each special management area. The fact that activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas.

16 USC §544O(a)(10). The remainder of this section therefore focuses on describing potentially applicable provisions of the Skamania County Comprehensive Plan and SCC Titles 21, 20, and 21A. For additional information of the provisions of the National Scenic Area Act, see Section 4.11 of this EIS.

3.8.2.1 Skamania County Comprehensive Land Use Plan

On July 10, 2007, Skamania County adopted its current Comprehensive Plan, which includes three Subarea Plans. The Project Area is not located in one of these subareas. There are three land use designations outside of the specific subarea plans: Rural I, Rural II, and Conservancy (see Figure 3.8-4). The Project Area is designated as Conservancy. The Comprehensive Plan
identifies zoning that is consistent with the Conservancy designation, including: Residential 10 (R-10), Rural Estates 20 (RES-20), Resource Protection (FOR/AG 10 and 20), Commercial Resource Land 40 (CRL 40), Natural (NAT), and Unmapped Classification (UNM).

The alternative location of the Operations and Maintenance facility is in the Rural II designation of the Comprehensive Plan. Most residential zoning classifications are consistent with the Rural II designation, as are the FOR/AG 10 and 20, NAT, and UNM zoning classifications.

The overall Comprehensive Plan vision statement is:

*Skamania County is strongly committed to protecting our rural character and natural resource based industries while allowing for planned future development that is balanced with the protection of critical resources and ecologically sensitive areas, while preserving the community’s high quality of life.*

Natural resources-based industry is further encouraged in the Comprehensive Plan’s description of the intent of the Conservancy designation:

*The Conservancy land use area is intended to provide for the conservation and management of existing natural resources in order to achieve a sustained yield of these resources, and to conserve wildlife resources and habitats. Much of the Conservancy land use area is characterized by rugged terrain, steep in slope, and unsuitable for development of any kind. Logging, timber management, agricultural and mineral extraction are main use activities that take place in this area. Recreational activities of an informal nature such as fishing, hunting, and hiking occur in this area, although formal recreational developments may occur from time to time. Conservancy areas are intended to conserve and manage existing natural resources in order to maintain a sustained resource yield and/or utilization.*

Among the uses identified as appropriate in the Conservancy designation are: public facilities, utilities, utility substations, forest management (including temporary logging and mining camps), and surface mining (by conditional use).

The Rural II designation is described in the Comprehensive Plan as follows:

*“The Rural II land use area is intended to provide for rural living without significant encroachment upon lands used for agriculture and timber. This land use area is the middle developmental range level suggested by this plan. The lower density will help to protect agricultural and timber lands from dense residential type development, and should maintain the rural character of this designation.”*
Figure 3.8-4
Skamania County Zoning

Whistling Ridge Energy Project
Conditional Use Permit Application

Job No. 33758687
Among the non-residential uses identified in the Comprehensive Plan as appropriate in the Rural II designation are public facilities, utilities, utility substations, telecommunication facilities, hospitals, meeting halls, agriculture, forest management including temporary logging and mining camps, and surface mining.

The following identifies potentially applicable goals and policies in the Comprehensive Plan.

**Goal LU.1:** To integrate long-range considerations (comprehensive planning) into the determinations of short-term action (individual development applications).

*Policy LU.1.2:* The plan is created on the premise that the land use areas designated are each best suited for the uses proposed therein. However, it is not the intention of this plan to foreclose on future opportunities that may be made possible by technical innovations, new ideas and changing attitudes. Therefore, other uses that are similar to the uses listed here should be allowable uses, review uses or conditional uses, only if the use is specifically listed in the official controls of Skamania County for that particular land use designation.

**Goal LU.2:** To provide for orderly future physical development of Skamania County.

*Policy LU.2.4:* Encourage new commercial enterprises to locate within or near existing commercial areas to avoid further scattering and to better serve the public.

**Goal LU.3:** To coordinate public and private interests in land development.

*Policy LU.3.3:* Encourage industry that would have minimal adverse environmental or aesthetic effects.

**Goal LU.4:** To promote interagency cooperation and effective planning and scheduling of improvements and activities so as to avoid conflicts, duplication and waste.

*Policy LU.4.3:* Land use patterns, which minimize the cost of providing adequate levels of public services and infrastructure, should be encouraged.

**Goal LU.5:** To promote improvements which make our communities more livable, healthy, safe and efficient.

*Policy LU.5.5:* Promote compatibility of industry with the surrounding area or community by fostering good quality site planning, landscaping, architectural design, and a high level of environmental standards.
Policy LU.5.6: Encourage commercial development that is convenient, safe and pleasant to the general public by: requiring that new establishments provide off-street parking adequate for its needs. Encourage pooled or joint use parking areas for adjacent developments may be utilized; Regulate access points for vehicular traffic for commercial areas to prevent unsafe conditions; the design of commercial sites, buildings, and signs should be compatible with surrounding areas; and, landscaping may be required as a buffer when commercial use adjoins residential or farm property.

Goal E.1: To ensure the proper management of the natural environment to protect critical areas and conserve land, air, water, and energy resources.

Goal T.1: Transportation – Encourage an efficient multi-modal transportation network that is based on regional priorities and coordinated with county and city comprehensive plans.

Goal T.2: Continue the priority of increasing safety of the Skamania County rural 2-lane road system. The majority of the Public Works Department’s future efforts will be to reduce the accident rate with Skamania County.

Goal T.3: Public Facilities and Services – Ensure that those public facilities and services necessary to support development should be adequate to serve the development at the time the development is available for occupancy and use without decreasing current service levels below locally established minimum standards.

Goal AHP.1: Identify and encourage the preservation of lands, sites, and structures that have historical or archaeological significance.

Goal AHP.2: Increase recognition of historic, archaeological, and cultural resources.

Goal AHP.3: Protect historic, archaeological and cultural resources through a comprehensive planning approach.

3.8.2.2 Skamania County Zoning Ordinance SCC Title 21

Title 21 of the Skamania County Zoning Ordinance is the county zoning that applies to the Project Area. Although extensive updates of SCC Title 21 have been proposed for adoption, the last-adopted version is still in effect because the proposed updates are currently under appeal by local interest groups.

Under SCC Title 21, the Project Area is located primarily in the UNM zone, with the southern tip of the Project Area in the FOR/AG 20 zone (see Figure 3.8-5). Both of these zoning classifications are consistent with the Comprehensive Plan’s Conservancy designation for this area. None of the Project Area is designated as farmland.
Approximately 7,152 acres of the 1,152-acre Project Area are located in the UNM zone. UNM zones are those areas of the county where no formal adoption of any zoning map has taken place. The Skamania County Code provides:

In the UNM zone all uses which have not been declared a nuisance by statute, resolution, ordinance or court of jurisdiction are allowable. The standards, provisions, and conditions of this title [SCC Title 21] shall not apply to unmapped areas.

SCC 21.64.020. Nuisances established by the Board of County Commissioners by resolution and ordinance are identified in SCC 8.30.010; this provision of the County Code does not identify wind energy facilities as a nuisance. In addition, neither the RCW nor the WAC designate wind energy facilities as a nuisance.

In July 2007, the County adopted a moratorium on unincorporated UNM-zoned lands outside the Swift Subarea. The moratorium does not prohibit all development in UNM lands. Rather, it restricts three types of land uses: (1) issuance of building permits on lands created by deed since January 2006 that are 20 acres or larger; (2) land divisions (short plat and subdivision); and (3) acceptance of SEPA checklists in support of converting land to non-forestry uses.

The remainder (approximately 400 acres) of the Project Area is located within the FOR/AG 20 zoning classification (see Figure 3.8-5). Pursuant to SCC 21.56.010[A]), the purpose of this zone is:

To provide land for present and future commercial farm and forest operations in areas that have been and are currently suitable for such operations, and to prevent conflicts between forestry and farm practices and nonresource production uses by not allowing inappropriate development of land within this zone classification.
Figure 3.8-5
Land Use within Five Miles of the Site

Whistling Ridge Energy Project
Conditional Use Permit Application
Uses allowed outright in the FOR/AG 20 zone include the following:

A. Forestry practices and associated management activities of any forest crop in accordance with Washington Forest Practices Act of 1974 including timber, Christmas trees, nursery stock, and surface mining.

B. Commercial and domestic agriculture.

C. Orchards and vineyards.

D. Horticulture.

E. Cottage occupation (in accordance with Chapter 21.70).

F. Light home industry (in accordance with Chapter 21.70).

G. Management of unique biological areas.

H. Management and propagation of fish and wildlife.

I. Water resources management facilities.

J. Storage of explosives, fuels and chemicals.

K. Accessory uses normally associated with an allowable use.

L. Public and private conservation areas or structures for retention of water, soil, open space, forest, or wildlife resources.

M. Log sorting and storage areas, scaling stations, temporary crew quarters, forest industry storage and maintenance facilities.

N. Family day care home (in accordance with Section 21.86.020).

O. Residential care facilities (in accordance with Chapter 21.85).

P. Farm labor housing.

Q. Accessory equipment structures.

R. Attached communication facilities not located on BPA towers (in accordance with Section 21.70.160).

Uses allowed by Conditional Use Permit in the FOR/AG 20 zone include:

A. Individual single-family residences not provided in conjunction with forest or farm management, including residential and resource related development may be permitted conditionally, provided they meet (...additional listed conditions).

B. Recreational facilities.

C. Semi-public facilities and utilities.

D. Sawmills, shake and shingle mills, chippers, pole and log yards.

E. Geothermal energy facilities.

F. Aircraft landing fields.
G. Cluster developments.

H. Child mini-day care center (in accordance with Section 21.86.030).

I. Child day care center (in accordance with Section 21.86.040).

The alternative Operations and Maintenance facility site is located approximately 0.9 mile west of the Project Area in the R-5 zoning classification (see Figure 3.8-5). This zoning classification is consistent with the Comprehensive Plan’s Rural II designation for this area. Pursuant to SCC 21.36.010, the purpose of the R-5 zone is:

To provide a transition zone of medium to low density residential development which will maintain a rural character of the area in the Rural II Land Use Area of the County Comprehensive Plan A.

Uses allowed outright in the R-5 zone include the following:

A. Single-family dwellings
B. Commercial and Domestic agriculture
C. Forestry
D. Public facilities and utilities
E. Cottage occupation (In accordance with Chapter 21.70)
F. Light home industry (In accordance with Chapter 21.70)
G. Residential care facilities (In accordance with Chapter 21.85)
H. Family day care home (In accordance with Chapter 21.86.020)
I. Safe home
J. Accessory equipment structures
K. Attached communication facilities located on BPA towers. (in accordance with Section 21.70.160)

Uses allowed by Conditional Use Permit in the R-5 zone include:

A. Surface mining
B. Recreational facilities
C. Professional services
D. Geothermal energy facilities
E. Public displays
F. Cluster developments
G. Semi-public facilities
H. Small and Large-Scale Recreational Vehicle Parks.

I. Child day center (In accordance with Chapter 21.86.040)

3.8.2.3 Skamania County Code, Title 20, Shorelines

Because the Project Area is not located near or on any shorelines of State, County or other significance, there are no applicable provisions of this county code.

3.8.2.4 Skamania County Code, Title 21A, Critical Areas

The Washington State Growth Management Act, RCW 36.70A.060, requires counties to identify and regulate critical areas. Critical areas include:

- Fish and wildlife habitat conservation areas
- Frequently flooded areas
- Geologically hazardous areas
- Ponds and lakes
- Streams, creeks, and rivers

In Skamania County, critical areas regulations are found in SCC Title 21A. The Project Area is not located within any critical recharge areas, frequently flooded areas, ponds and lakes, or rivers. Portions of the Project Area are located near geologically hazardous areas due to steep slopes classified as Class II and III LHAs. There are wetlands, fish and wildlife habitat areas, streams, and creeks on the site.

3.8.3 IMPACTS

Adverse impacts to land use can are defined two ways:

- Changes to existing land use activities and development patterns. The Project could cause adverse impacts if it were to preclude the continuance of existing land uses or cause major changes to the existing patterns of land use activities or development.

- Inconsistency of a proposed project with existing land use regulations. The Project could cause adverse impacts if it was found to be inconsistent with the Skamania County Comprehensive Plan, Zoning Code, or Critical Areas regulations.

---

3.8.3.1 Proposed Action

Changes to Existing Land Use Patterns and Recreation

Project Construction

During construction, earth movement and construction-related traffic would generate noise and dust that could temporarily affect nearby homes and businesses located along the site access route (described in Section 3.11, Transportation). Cook-Underwood Road would be the primary access route for construction materials and workers. However, construction impacts would not be sufficient to cause changes to existing land use patterns.

Land clearing for the construction of the alternative Operations and Maintenance facility site would occur concurrently with roadway improvements to West Pit Road. The additional earth movement and construction-related traffic would generate slightly more noise and dust in that area along West Pit Road over anticipated levels for roadway construction without the facility. The additional noise and dust could temporarily affect nearby homes along Willard Road. Construction impacts would not be sufficient to cause changes to existing land use patterns.

Construction would not directly affect local recreational facilities beyond the potential for construction workers to use local recreational facilities during the one year construction period. Existing limits on the length of stay in public camping areas would minimize any potential impacts on park users from construction workers staying in parks, and a majority of the construction workers are expected to be within daily commuting distance of the site. Additionally, workers who did stay at local parks would most likely do so on weekdays and would thus not be there on the days with the highest levels of use.

Construction activities could affect some recreation users such as users of the Underwood Park and Community Center located along Cook-Underwood Road, through temporary increases to traffic, and from construction-related dust and noise. These impacts would be temporary and are expected to be minor.

Construction of the Operations and Maintenance facility at the West Pit Road location would not impact local recreational facilities. Existing limits on the length of stay in public camping areas would minimize any potential impacts on park users from construction workers staying in parks, and a majority of the construction workers are expected to be within daily commuting distance of the site. Additionally, workers who did stay at local parks would most likely do so on weekdays and would thus not be there on the days with the highest levels of use.

Construction of the Operations and Maintenance facility at the West Pit Road could affect some recreation users through temporary increases to traffic, and from construction-related dust and noise. Impacts would be primarily limited to recreational users traveling on Cook-Underwood Road. This impact would not be noticeably different from the construction of the on-site location. Construction impacts would be temporary and are expected to be minor.

Project Operation

Project operation also would not cause changes to existing land uses or land use activities or development patterns. The surrounding land uses are predominantly commercial forestry,
agriculture and residential, and these uses would not be directly negatively affected by the Project (Figure 3.8-5). The majority of the Project Area itself would remain in commercial forest production, with a maximum of approximately 56 acres of land (under 5 percent) converted to non-forestry uses related to new and widened roads, the turbine strings, the Operations and Maintenance facility, and the substation. At decommissioning, all of these facilities would be removed and the area returned to commercial forest.

Project operation would not force any changes in forestry operations or activities on the rest of the Project Area or on surrounding properties. The Project would not generate sufficient amounts of noise, traffic, visual changes, energy use, air emissions or water use to cause changes to these existing land use patterns.

Concern was expressed during scoping that the visibility of the turbines would cause a negative impact on agricultural tourism, specifically visits to area wineries. Wind power and winery tourism already co-exist in the Columbia River area. For example, four wind power facilities are located between Walla Walla and Kennewick (Canyon, Stateline, Vansycle, and Combine Hills). This area is home to a thriving wine industry with over 60 wineries. Section 3.9 Visual Resources discusses visual impacts.

Project operation would not result in a sufficient increase in population or traffic to impact local recreational facilities. The only potential impact to recreation users would be the minor to moderate visual impacts discussed in Section 3.9 Visual Resources.

Operation of the alternative Operations and Maintenance facility would not change existing land use patterns. The surrounding land uses are predominantly commercial forestry, agriculture and residential, with the nearest home approximately 0.25 mile away. The site is adjacent to West Pit Road, which would be used for access to the Project Area during both construction and operation. Use of the alternative site for the Operations and Maintenance facility would generate noise, traffic, new lighting, energy use, air emissions, and water use, but not at levels sufficient to cause changes to the existing surrounding land uses. The Operations and Maintenance facility thus would be compatible with surrounding land use and would not hinder the development of permitted land uses on neighboring properties.

**Project Decommissioning**

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is suspended or terminated during construction or before it has completed its useful operating life. The plan would include or parallel a decommissioning plan for the Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential changes to land use, recreation or recreational access. If impacts to land use or recreation are anticipated to occur as a result of site restoration and Project decommissioning, mitigation measures would be proposed as part of the plan.
Consistency with Applicable Land Use Regulations

Overall, the proposed project would be consistent with applicable land use regulations. The Project would not involve subdividing any land parcels nor applying for changes to zoning or Comprehensive Plan designations. In a letter to EFSEC dated May 4, 2009, Skamania County found that the proposed Project is consistent with the Skamania County Comprehensive Plan, SCC Title 21 Zoning Code, SCC 21A Critical Areas, Title 24 Clearing and Grading, and resource maps. On December 22, 2009, the Skamania County Board of County Commissioners passed Resolution 2009-54, resolving that the revised project, including the use of the alternative location of the Operations and Maintenance facility and the use of the West Pit Road as an access route, is consistent with Skamania County Land Use Plans and applicable zoning ordinances (see Appendix D Land Use Consistency Determination). When a county certifies consistency with its local land use plans and ordinances, pursuant to WAC 463-26-090, the plan states that “such certificates will be regarded as prima facie proof of consistency and compliance with such land use plans and zoning ordinances absent contrary demonstration by anyone present at the hearing.”

The following further evaluates the consistency of the proposed Project with applicable land use regulations.

Skamania County Comprehensive Land Use Plan

The Project would be consistent with the Comprehensive Plan vision and the Conservancy designation in that it would conserve and manage existing natural forest and wind resources to maintain a sustained yield and utilization of both. Within the Conservancy designation, public facilities, utilities, and utility substations are allowed. Wind energy facilities are consistent with the Conservancy designation because they are utilities. The Project would provide an alternative source of electrical energy generation that is not reliant on either fossil fuels or hydropower, while allowing forest management activities to continue around the turbine corridors. In addition, the staff report attached to Skamania County Resolution 2009-54 documents the County’s determination that the proposed Project would be a semi-public facility under SCC Title 21 (see Appendix D). Semi-public facilities are defined in SCC 21.08.010 as “facilities intended for public use which may be owned and operated by a private entity.” The Project thus would be a utility consistent with the Conservancy designation’s appropriate uses.

The alternative location for the Operations and Maintenance facility on West Pit Road would include an approximately 3,000-square-foot building, located on a 5-acre parcel in an area designated as Rural II in the Comprehensive Plan. The facility would be similar in size to a larger single family home. The Project would be a utility that is consistent with the Rural II designation and would not conflict with any of the goals or policies expressed in the Comprehensive Plan.
Skamania County Zoning Ordinances

The portion of the proposed Project that would be located in the UNM zoning classification would be considered consistent with this zoning. There is no conflict from siting wind energy facilities in the UNM zone, and these facilities have not been identified as a nuisance by statute, resolution, ordinance, or court order. Concerning the County’s moratorium on unincorporated UNM-zoned lands, the Project is not sited on lands created by deed since January 2006 and does not involve any land division. Because of Washington EFSEC’s preemptive role in permitting wind energy facilities, including acting as Lead Agency for associated SEPA review, the County’s moratorium on acceptance of SEPA checklists for forest practices conversions does not affect the Project.

Turbine Corridor A1–A7, with approximately seven turbines, would be located in the small portion at the southern tip of the Project Area that is within the FOR/AG 20 zone. If the proposed Project were being permitted through Skamania County rather than through Washington EFSEC, it is probable that a Conditional Use Permit from the County would be required for siting these turbines. Since Washington EFSEC is the permitting authority in this case, no such permit is required. Nonetheless, this portion of the proposed Project would be consistent with the purpose and intent of the FOR/AG 20 zone in which it would be located, and while not an outright allowed use, this Project is considered to be semi-public facility that would be a conditional use in this zone. As discussed above, the Project also would provide renewable energy generation while allowing forest management activities to continue around the turbine corridors. The portion of the proposed Project that would be located in the FOR/AG 20 zone thus would be considered consistent with this zoning.

The proposed alternative Operations and Maintenance facility located along West Pit Road would be within an area zoned R-5. Like turbine Corridor A1–A7, if the County was the permitting authority for the alternative Operations and Maintenance facility, a Conditional Use Permit likely would be required. However, Washington EFSEC is the permitting authority and no such permit is required. Nonetheless, the alternative Operations and Maintenance facility would be consistent with the purpose and intent of the zone in which it would be located. The Operations and Maintenance building would be located on a 5-acre site, and, at 3,000 square feet, would be similar in size to a larger single-family residence. The building would meet all applicable setback requirements, and would not pose a hazard to the health, safety or welfare of the surrounding community. Traffic associated with the facility would be similar to traffic from staff currently involved in ongoing timber management in the area. A well and on-site septic system would be installed to provide potable water for the Operations and Maintenance building. The anticipated demand for fire and police services would be low, and similar to other commercial operations in the Project vicinity. Development of the facility would not hinder or discourage development or continuation of timber management activities on nearby properties, or of residential properties in the area. Finally, the facility would not conflict with the goals and policies expressed in the current version of the County’s Comprehensive Plan. Accordingly, location of the alternative Operations and Maintenance facility in the R-5 zone would be considered consistent with this zoning.

The proposed Project also would be consistent with the critical areas regulations found in SCC Title 21A. The Project Area is not located within any critical recharge areas, frequently flooded
areas, ponds and lakes, or rivers. Portions of the Project Area are located near geologically hazardous areas due to steep slopes classified as Class II and III LHAs. There are wetlands, fish and wildlife habitat areas, streams, and creeks on the site. The Project has been designed to minimize impacts to these areas, as discussed in Section 3.8.4, Mitigation Measures, and primarily in Section 3.3 Water and 3.4 Biological Resources.

Improvements to West Pit Road to widen it in places also would be consistent with SCC Title 21A. The use of the West Pit Road would not create safety concerns. While no new construction would occur within wetlands, streams, or their buffers, West Pit Road crosses one unnamed drainage in the Lapham Creek watershed. In July 2009, the drainage had observed flow through the existing culvert under West Pit Road, but the surface flow and the channel disappeared downstream of the culvert. The drainage is classified as a Class V stream under SCC 21A.04.020(B), Appendix C. Buffers are established for Class V streams, within which expansion of existing uses is allowed. As long as the proposed expansion or widening is 100 percent or less than the existing footprint, no development review is required under SCC 21A.05 and SCC 21A.06 in fish and wildlife protection areas or geologically hazardous areas. The road improvements in these regulated fish and wildlife protection areas do not exceed the allowed expansion threshold. For a full discussion of fish, wildlife, their habitats, and Project impacts to these, please see Section 3.4 of the Application for Site Certification.

Columbia River Gorge National Scenic Area Management Plan

While the proposed Project would be located entirely outside of the Columbia River Gorge National Scenic Area, concerns have been raised regarding the compatibility of the Project with the objectives and policies of the National Scenic Area Management Plan. The following identifies key objectives and policies, along with a discussion of Project consistency with each of these objectives and policies.

- **Protection of Resources.** The Project would not decrease any resources within the Scenic Area. Neither the site nor its access roads are within the Scenic Area, and no recreation resources would be lost.

- **Scenic Appreciation and Scenic Travel Corridors.** The Project would have minor to moderate impacts on visual quality as viewed from travel corridors inside the Scenic Area. See Section 3.9 Visual Resources.

- **Resource Based Recreation.** No resource-based recreation resources are within or in proximity to the Project Area. The only potential impact to recreation in the Scenic Area would be incidental recreational use by construction workers during the construction period. Such use is expected to be minimal.

- **River Access and Protection of Treaty Rights.** This Project is on private lands outside of the Scenic Area and would have no effect on river access or treaty rights.

- **Interpretation/Education.** An opportunity to provide alternative energy interpretation and education could be included in this Project and further the goals of the Scenic Area.
- **Trails and Pathways.** The Project would not directly affect any trails or pathways in the Scenic Area. There may be some distant views of wind turbines from trails; the impact is expected to be “low to moderate.” See Section 3.9 Visual Resources.

- **Transportation.** Portions of SR 14 and portions of Cook-Underwood Road that are within the Scenic Area would be used to access the Project. Increased traffic would cause a temporary and limited impact to recreational travelers during the construction period.

- **Coordination.** The Project Area and access roads are located outside of the Scenic Area. No coordination is required.

### 3.8.3.2 No Action Alternative

Under the No Action Alternative, the Project would not be built. The site would continue to be used for commercial forestry and timber harvest would continue on a regular rotating schedule. Accordingly, existing land uses at the Project Area would remain unchanged. In addition, the informal recreation activities at the Project Area would remain largely the same, and no effect on recreational uses in surrounding areas would occur. The current level of consistency with land use plans and regulations also would continue to exist under this alternative.

### 3.8.4 MITIGATION MEASURES

No substantial impacts to land use are identified and no mitigation measures are required. The only potential impact to recreation users from operation would be the minor to moderate impact to visual resources from some viewpoints. Mitigation for this potential impact is identified in Section 3.9, Visual Resources.

### 3.8.5 UNAVOIDABLE ADVERSE IMPACTS

The 1,152-acre Project Area would continue to be predominantly used for commercial forestry operations. A maximum of approximately 56 acres of forestry land (under 5 percent of the Project Area) would be converted to energy facility use for the life of the Project. This conversion would not constitute a substantial change to area land use patterns given the area of the Project retained for active forestry operations, and given the acreage surrounding the Project in both private and state ownership that would be maintained in commercial forestry operations.

### 3.9 VISUAL RESOURCES

This section describes potential impacts to visual resources. It assesses the potential for visual impacts using accepted methods of evaluating visual landscape quality and predicts the type and degree of effects the Project would likely have on those attributes. This section also identifies mitigation measures designed to minimize those impacts.
3.9.1 METHODOLOGY

This section summarizes the visual impact assessment performed for the Application for Site Certification Agreement. The visual assessment used the Scenery Management System defined in *Landscape Aesthetics, A Handbook for Scenery Management* (USFS 1995) and *Visual Impact Assessment for Highway Projects* (FHWA 1988). The study was also designed to respond to the provisions of WAC 463-42-362, Built Environment–Land and Shoreline Use, which specifies the analysis of aesthetic and light and glare issues as part of the EFSEC process.

The Federal Highway Administration (FHWA) methodology is widely used for visual assessment of private lands such as the Project area, where visual quality objectives have not been established. A visual quality objective is a resource management objective established by a district manager or contained in a plan that reflects the desired level of visual quality based on the physical characteristics and social concern for the area. Five categories of visual quality objectives commonly used are preservation, retention, partial retention, modification, and maximum modification.

The FHWA methodology has been used to evaluate other recent wind power projects, including the Desert Claim project19, Lower Snake River (FHWA and BLM) and the Kittitas Valley project (FHWA and USFS methodologies)20. The FHWA method is also used where linear features of the Project such as roads or turbine strings move into differing landscapes and visual corridors with differing view groups.

Three methodologies are commonly used to analyze visual impacts in federal and state EISs: the FHWA and USFS methodologies used for this Project, and the Visual Resource Management system used by the BLM21. The BLM methodology is generally used where projects are proposed on or in proximity to BLM lands and visual resource objectives for specific planning areas are already established. Under the BLM methodology a contrast rating can be completed and compared to the established BLM visual classifications. In order to use the BLM process for projects on private lands where no visual resource objectives have been established, it would be necessary to complete a full visual management inventory to delineate all lands in question and then classify each delineated area using the BLM classifications. The FHWA process provides for establishing existing visual quality objectives at a smaller scale or project level.

The BLM analysis would then determine whether and how the project features meet the objectives of the classification using the Visual Resource Management process for contrast rating. The FHWA process also follows this process, but is more conducive to a project of this scale and complexity. Full-scale Visual Resource Management delineation and classification are more appropriate for land management planning on a large scale and for providing visual objectives for public lands with multiple management objectives and uses.

21 See: http://www.blm.gov/nstc/VRM
While the FHWA process does not rely on pre-existing visual quality objectives, it does incorporate elements of the Scenery Management System, which is part of both the USFS and BLM methodologies establishing existing visual quality and process for determining visual contrast. The FHWA process incorporates Scenery Management System and Visual Resource Management components, including landscape features, ecological conditions, cultural settings, and social needs to establish the existing visual conditions and the effects of a project on the visual environment.

The methodology used is appropriate since it provides a clear understanding of how the proposed Project would affect the visual landscape as seen from the key viewing areas. This methodology portrays the differing viewer groups and their sensitivity to visual change, defines distance zones (foreground, middle ground and unseen areas) and evaluates the contrast between pre- and post-project conditions as seen from the different viewpoints, by different viewer groups, and from different distances.

This analysis of visual effects was based on field observations and review of wind energy facilities’ visual effects, public perception, design measures to reduce visual impacts, and local planning documents. Project maps, drawings, technical data, and computer-generated viewshed maps were used to determine areas where the Project would be visible, and visual simulations were generated (described in Section 3.9.1.3) to illustrate the change from the existing conditions if the Project is implemented. The analysis included systematic documentation of the visual setting, evaluation of visual changes associated with the Project, and measures designed to mitigate these visual effects. Mitigation measures include restoration or enhancement activities in areas that would be disturbed during construction.

3.9.1.1 Scenic Quality Assessment

Scenic quality ratings were developed based on observations in the field, photographs of the affected area, methods for assessing visual quality, and research on public perceptions of the environment and scenic quality ratings of landscape scenes. The final assessment of scenic quality was made based on professional judgment that took a broad spectrum of factors into consideration, including:

- Natural features, including topography, watercourses, rock outcrops, and vegetation
- The positive and negative effects of human alterations and built structures on visual quality
- Visual composition, including an assessment of the vividness, intactness, and unity of patterns in the landscape, defined as:
  - Vividness refers to the memorability of the visual impression received by the viewer from contrasting landscape elements as they combine to form a striking and distinctive visual pattern;
Intactness is the integrity of visual order in the natural and human landscape, and the extent to which the landscape is free from visual encroachment;

Unity is the degree to which the visual resources of the landscape join together to form a coherent and harmonious visual pattern.

Each viewpoint was assigned a final rating based on the rating scale shown in Table 3.9-1. This rating scale incorporates the landscape assessment concepts developed in the USFS and FWHA methodologies.

### Table 3.9-1
**Landscape Scenic Quality Scale**

<table>
<thead>
<tr>
<th>Visual Quality Rating</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Outstanding 6</td>
<td>A rating reserved for landscapes with exceptionally high visual quality. These landscapes are significant nationally or regionally. They usually contain exceptional natural or cultural features that contribute to this rating. They are what we think of as “picture postcard” landscapes. People are attracted to these landscapes to view them.</td>
</tr>
<tr>
<td>High 5</td>
<td>Landscapes that have high quality scenic value. This may be due to cultural or natural features contained in the landscape or to the arrangement of spaces contained in the landscape that causes the landscape to be visually interesting or a particularly comfortable place for people. These landscapes have high levels of vividness, unity, and intactness.</td>
</tr>
<tr>
<td>Moderately High 4</td>
<td>Landscapes that have above average scenic value but are not of high scenic value. The scenic value of these landscapes may be due to human or natural features contained within the landscape, to the arrangement of spaces in the landscape, or to the two-dimensional attributes of the landscape. Levels of vividness, unity, and intactness are moderate to high.</td>
</tr>
<tr>
<td>Moderate 3</td>
<td>Landscapes that are common or typical landscapes with average scenic value. They usually lack significant human or natural features. Their scenic value primarily results from the arrangement of spaces contained in the landscape and the two-dimensional visual attributes of the landscape. Levels of vividness, unity, and intactness are average.</td>
</tr>
<tr>
<td>Moderately Low 2</td>
<td>Landscapes that have below average scenic value but not low scenic value. They may contain visually discordant human alterations, but these features do not dominate the landscape. They often lack spaces that people perceive as inviting and provide little interest in terms of two-dimensional visual attributes of the landscape.</td>
</tr>
<tr>
<td>Low 1</td>
<td>Landscapes that have below average scenic value. They may contain visually discordant human alterations, and often provide little interest in terms of two-dimensional visual attributes of the landscape. Levels of vividness, unity, and intactness are below average.</td>
</tr>
</tbody>
</table>

### 3.9.1.2 Visual Sensitivity Assessment

The analysis also assessed visual sensitivity, which involves predicting the general impact on the quality of views from a given viewpoint. A combination of three factors determines how sensitive a landscape scene is:

- The number and type of viewers
- The viewing conditions
- The quality of the view
Residential areas with unobstructed views of a regionally important and memorable scene would be very sensitive to objects or structures that would impede views. A view from a seldom-traveled rural road where motorists have only distant, oblique views of wind turbines in an unremarkable setting would likely qualify as an area of low sensitivity.

The principal types of viewers in the Project Area who have predictably high levels of sensitivity to visual impacts include:

- Resident viewers;
- Roadway viewers (drivers and passengers); and
- Recreating viewers such as hikers, water recreationists, and mountain bikers.

This analysis defines three levels of visual sensitivity:

- **Low.** Viewer types representing low visual sensitivity include agricultural and industrial/warehouse workers. Compared with other viewer types, the number of viewers is generally considered small and the duration of view is short. Low levels of sensitivity are assigned to areas 5 miles or more from the closest turbine, where a wind power project would be a distant and a relatively minor element in the overall landscape.

- **Moderate.** Viewer types representing moderate visual sensitivity consist of highway and local travelers. The number of viewers varies depending on location; however, on average they tend to be moderately large, based on overall densities of surrounding areas and highway commuters. Viewer awareness and sensitivity are also considered moderate because destination travelers often have a focused orientation. Moderate levels of sensitivity were assigned to areas where turbines would be visible from 0.5 mile to 5 miles within the primary view of residences and roadways. The primary view refers to the central area that the eye can see clearly without moving and is surrounded by the peripheral vision. In distinguishing between moderate and low levels of sensitivity in the 0.5-mile to 5-mile zone, contextual factors were also considered, including the viewing conditions in the immediate foreground of the view.

- **High.** Residential, recreational, and viewers congregating in public gathering places (churches, schools, trails, designated scenic viewpoints, etc.) are considered to have comparatively high visual sensitivity. The visual setting may in part contribute to the enjoyment of the experience. Views may be of long duration and high frequency. High levels of sensitivity are generally assigned in those cases where turbines would be potentially visible within 0.5 mile or less from residential properties, heavily traveled roadways, or heavily used recreational facilities. The principal types of viewers in the Project Area who have predictably high levels of sensitivity to visual impacts include residential viewers, roadway viewers (drivers and passengers) and recreating viewers such as hikers, water recreationists, and mountain bikers.

These criteria were used to establish the sensitivity levels of each view using a systematic approach based on the distance of the Project from the viewpoint, the number of turbines or
percentage of the Project Area that could be viewed from this viewpoint, and the dominant viewer types for each view. Through this analysis, an overall sensitivity rating was established for each existing landscape view.

### 3.9.1.3 Preparation of Visual Simulations

Visual simulations were developed using photographs taken with a 35 mm digital SLR camera. Various focal lengths from 40 to 70 mm were used with the intent to capture the maximum pixels and resolution for the simulation. Visual Nature Studio, a widely-used three-dimensional Geographic Information System (GIS) software, manufactured by 3D Nature, LLC, was used to model the turbine locations on terrain built from USGS digital elevation model data. The photo locations were camera-matched in the software to render the turbines from the same viewpoint as the photographs taken on the ground. The resulting rendered turbine images were then photocomposited into the photographs to create the simulations. Existing topographic and site data provided the basis for developing the initial digital model.

In preparing the visual simulations, the turbine model used was the 2.5-MW Clipper Liberty model C93, which was considered a likely model to be selected based on information provided by the Applicant. This model has an overall height to nacelle of 80 m (262 feet) and blade diameter of 93 m (305 feet), and a blade length of 45.2 m (153 feet). The overall height to the tip of a stationary, vertical blade is 126.5 m (415 feet). The actual turbine size has not been determined, but potential turbines are estimated to have a height to nacelle of 262 feet and blade length between 129 and 164 feet.

Simulations were prepared assuming a conservative scenario of 50 turbines. This approach to creating simulations most likely overstates the visual impacts. This is because the Applicant has applied for EFSEC certification for a maximum of 75 MW. If 2.5 MW turbines were to be used, only 30 turbines could be built, and overall visual impact would be less. If lower-power turbines were used, the turbines would be smaller and thus less visible. Further, in evaluating impacts, the turbine is considered visible if any part of a vertical turbine blade is visible. In practice, turbines with only a part of the blade visible would not be seen when the blade is moving or is stationary but not vertical.

Atmospheric haze varies by location, season, time of day, and weather patterns. In creating photo composite visual simulations, the aim is to match the haze level on the rendered turbines to the observable haze present in the photograph. This is done by comparing the haze effects on the photographed terrain near the turbines to the rendered haze effects on the rendered terrain. This is then translated into a worst-case (lower than expected) haze visibility setting for the turbine renders. The result is that the turbines would be slightly more visible in the final composites than they would actually be if an observer were standing on the ground viewing them from the exact place, date, and time that the photos were taken.

The sky depicted in some of the visual simulations includes clouds, simulating the cloudy conditions that are common at the site.

Site plans and specifications for the proposed wind turbines were used to create three-dimensional digital models of the planned turbine placements. These models were combined
with the digital terrain model to produce a complete computer model of the wind facility. For each viewpoint, a render camera was placed in the Visual Nature Studio software. The aspect ratio of each render was then matched to the corresponding photograph and the rendered terrain was visually matched to the photographed terrain to confirm scale. Finally the resulting turbine images were matched in perspective, scale, and aspect ratio, are photo-composited into the original digital photo base using Adobe Photoshop. This process produces accurate portrayals of how the given turbine models and placements would look on the given terrain and from the specified viewpoints after construction. Seasonal conditions including weather, air quality, vegetation (foreground and background) and color impact the quality of the compositions. These compositions are a representative example of the area without subjectivity.

Simulations were not developed for nighttime conditions. Night simulations are inherently inaccurate, since they do not show the periodic flashing of the air warning lights, which is the impact most often mentioned. Night simulations are not typically performed as part of the analysis of wind power projects, and have not been requested by EFSEC. The potential impact of air warning lights is discussed in Section 3.9.3.1.

3.9.2 AFFECTED ENVIRONMENT

Each landscape has a specific quality that gives a geographic area its visual and cultural image, and consists of the combination of physical, biological, and cultural attributes that make each landscape identifiable or unique. The character of an existing landscape may range from a predominantly natural landscape to landscapes that are heavily culturally influenced. The existing scenic quality of an existing landscape includes the natural scenic attributes of the landscape in combination with the existing land use patterns. The list of attributes includes naturally evolving, natural appearing, pastoral, agricultural, or even urban landscapes and generally are at the broadscale or landscape level of the analysis, but can be analyzed for each specific viewpoint at a project level.

The sensitivity of a landscape or view of that landscape is based on the scenic integrity of the landscape and the types of viewers. A landscape that has a high degree of integrity is a landscape that has a sense of wholeness, intactness, or being complete. Its scenic quality is near-perfect, with no evident discordant elements or deviations from the existing character, making it highly sensitive to most changes and to the perceptions of the viewer types.

The existing visual resources are the natural and built features open to view in the Project landscape. The combination of land, water, and vegetation patterns represent the natural landscape features that define an area’s visual character, while built features such as buildings, roads, and other structures reflect human or cultural modifications to the landscape. These natural and built landscape features or visual resources contribute to the public’s experience and appreciation of the environment. This section describes the broad scale regional and local landscape settings that were used to establish appropriate viewpoints from which the Project would be visible.
3.9.2.1 Regional Landscape Setting

The Project is set in two distinct landscapes. One landscape is the areas were the turbines would be sited along ridges located on the northern plateau of the Columbia River Gorge on Underwood Mountain (Figure 1-1). The other landscape is the Columbia River Gorge National Scenic Area, which is outside the Project but within the viewshed looking into the Project Area. The Project Area is completely outside the Scenic Area, and therefore is not subject to the Columbia River Gorge Scenic Area Management Plan or related regulatory requirements. No improvements to Project Area roadways would take place in the Scenic Area.

The Scenic Area extends 85 miles along the Columbia River, and includes portions of three Oregon and three Washington counties. Formed by ancient volcanoes and sculpted by floods, the Columbia River Gorge carves a corridor through the Cascade Mountains in Oregon and Washington as the river journeys to the Pacific Ocean.

The National Scenic Area Act designated 292,500 acres on both sides of the Columbia River for special protection from the outskirts of Portland-Vancouver in the west to the semi-arid regions of Wasco and Klickitat counties in the east. The Scenic Area is categorized as SMAs, GMAs, and Urban Areas:

- SMAs contain the most sensitive resources. They total 114,600 acres and are managed by USFS.

- GMAs total 149,400 acres and include a mixture of historic land uses such as farming, logging, and cattle grazing. The Columbia River itself is currently designated as a GMA as well. Development on GMA lands is administered by the Gorge Counties and the Gorge Commission.

- Thirteen Urban Areas in the Gorge are exempt from any Scenic Area regulations: Cascade Locks, Hood River, Mosier, and The Dalles in Oregon, and North Bonneville, Stevenson, Carson, Home Valley, White Salmon, Bingen, Lyle, Dallesport, and Wishram in Washington. The Act’s second purpose is to protect and support the economy of the Gorge by encouraging growth in existing Urban Areas and by allowing future economic development in a manner that is consistent with protection and enhancement of resources.

The Project Area is outside of the Scenic Area Management Plan and no visual quality objectives or management designations have been established for the area. Areas south of the Project within the Scenic Area are designated as Urban or GMA. The views from the Gorge into the Project Area were examined through viewpoint selection. This area of the Gorge, closest to the Project, is considered to have a high visual quality with a moderate sensitivity based on the vividly memorable, and although the area is not free of visual encroachment, the visual resources join together with a moderate degree of unity.

3.9.2.2 Local Landscape Setting

The Project Area is on land managed for commercial forestry by the Applicant. All of the parcels on which the Project is located are managed for a continual cycle of growth, harvest, and
replanting. As a longstanding commercial forestry site, no old-growth forests exist in areas where the Project is proposed. Many of the stands of trees on the sections of land that would have turbines on them are recently harvested and reforested. The Applicant implemented timber harvest plans on approximately 50 acres during 2003. Additional harvests covering approximately 100 acres are planned as part of the ongoing commercial forestry operations (Figure 2-3).

In areas surrounding the proposed wind turbines that have not been recently harvested or that are not planned to be harvested before Project construction, trees would be harvested and most of the land would be replanted with seedlings. This clearing would allow for safe construction, and would reduce the potential for tree growth to interfere with the wind resource on the site during the commercial life of the Project. Low vegetation would be maintained in some areas to provide safe areas around the turbines (Figure 2-4).

No visual quality objectives have been established in the Project Area beyond the harvest size and configuration requirements of the Washington Forest Practices Act. These cleared areas are considered a “forest conversion” under the Forest Practices Act and have no established visual quality objectives. These openings, to the extent feasible, would be reforested in accordance with typical commercial forestry management practices.

S.D.S. Co., LLC and Broughton Lumber Company own this commercial property in Skamania County, Washington. The Project and the West Pit Road used for Project access are not located inside the Scenic Area. In relationship to the visual quality of the area, there are views from the Scenic Area into the Project Area. The viewpoints and viewer types in relation to the roadway improvements within the Scenic Area have been considered in this analysis for consistency with the Scenic Area guidance and conformance.

SR 14 in this area is a recognized scenic roadway. Typically, this designation means that a scenic corridor management plan would be prepared to provide policy-level guidance in the local adoption of comprehensive plan policies, zoning, and other land use regulation. There is no scenic corridor management plan for SR 14 and, therefore, no regulatory control of aesthetic impacts within the corridor. However, the scenic roadway designation carries an additional level of care and scrutiny in the review of potential aesthetic impacts based on recognition, but not regulation.

The local landscape visual appearance is of moderate visual quality with a moderate level of sensitivity. The levels of vividness (memorability), intactness (freedom from visual encroachment), and unity are average within the broader landscape. The immediate area of the Project Area is currently characterized by several types of visual disturbance. These include:

- BPA power transmission lines running east-west through the south and center portions of the Project Area;
- Williams gas pipeline running through the north portion of the Project Area, and compressor station just to the northwest of the Project Area;
- Two rock quarries west of the Project Area;
• Cell towers south of the Project Area in the Scenic Area;

• Forest openings from clear-cutting throughout and surrounding the Project Area; and

• Land clearing for agriculture especially south and east of the Project Area.

3.9.2.3 Viewpoints

To analyze the Project’s effects on visual resources, viewpoints were selected to characterize the aesthetic character of the Project Area and the differing landscapes in or near the Project. Most of the viewpoints are at publicly accessible locations which would have the largest number of viewers. Within the Columbia River Gorge National Scenic Area, Key Viewing Areas (KVAs) have been established as “those portions of important public roads, parks, or other vantage points with the scenic area from which the public views scenic area landscapes.” (SCC 22.04.010). Viewpoints included KVAs from which the Project could be seen, other viewpoints within the Scenic Area, and viewpoints outside the Scenic Area.

Figure 3.9-1 illustrates (with colored shading) how many of the turbines would be visible. No turbines are visible from several of the KVAs. For example, SR 14 is a KVA; however, the section of SR 14 nearest the Project Area has steep hills to the north, which block views of the Project Area. KVAs with no turbines visible were not selected as viewpoints for visual simulations and were not further analyzed.

Individual viewpoints were chosen based on the following criteria:

• Viewpoints that are most representative of the different roads, population areas, and recreation areas where views of the wind turbines would occur;

• Locations that are most accessible to the public; and

• Locations with the largest number of viewers (including residences).

Figure 3.9-1 shows the locations of these viewpoints and the number of turbines visible from each viewpoint. Views were not modeled from every residence from which the Project would be visible; however, residences and representative businesses between one and three miles from the Project Area are shown on Figure 3.9-2.

Each viewpoint was assessed for its scenic quality and viewer sensitivity. Scenic quality was determined by evaluating each viewpoint using the six levels of landscape scenic quality defined in Table 3.9-1 (Outstanding, High, Moderately High, Moderate, Moderately Low and Low). Viewer sensitivity for each viewpoint was determined by evaluating each viewpoint using the three levels of viewer sensitivity explained in Section 3.9.1.2 (Low, Moderate, and High). A rating was then applied to provide an overall average for the area. This process established the existing conditions for each of the individual viewpoints, from which impact of the Project on these parameters could be measured.
During scoping, a request was received that a visual simulation be prepared to depict views from Dog Mountain, a popular local hiking area and a Scenic Area KVA. To address this request, photos were taken from potential viewpoints located on the northeast and south side of the mountain. The photographs were used to assess views of the proposed Project, and to identify potential impacts to visual resources from those locations. It was determined that views of the Project Area were blocked by Cook Hill at all potential viewpoints located both on and off the trail. The Project would be visible from Cook Hill; however, there is no known recreational use in this area. Because the Project Area is not visible from Dog Mountain, scenic quality and viewer sensitivity were not rated, and no visual simulation was prepared to further assess potential impacts to visual resources.

This section describes the existing views from representative viewpoints. The viewpoint numbering below matches the numbering used in the Application for Site Certification. Additional viewpoints, which were excluded from this EIS as duplicative, can be found in the Application for Site Certification (Appendix A). Simulated photos depicting the existing view with proposed turbines are included in Section 3.9.3.

**Viewpoint 1: Pucker Huddle (Within Scenic Area)**

**Scenic Quality.** Viewpoint 1 is taken from SR 141, which is approximately 4 miles from the Project and is a small connector providing access to the Indian Heaven Wilderness in the Gifford Pinchot National Forest. This highway also allows access to several rural communities, including White Salmon, Husum, and Pucker Huddle. Most areas are unincorporated and several of the residences are recreational in nature with some year-round residences. As discussed in the review of the regional and local landscapes, no public roads pass through or are immediately adjacent to the Project.

Viewpoint 1 is a wide panoramic view of Underwood Mountain from SR 141 adjacent to the Pucker Huddle area. The view encompasses the east side of the Project Area and the ridged lines of forest management areas are visible in the middle ground of the viewshed. Natural openings are prevalent from this viewpoint, with several natural appearing features of openings and vegetation that provide an interesting view. The BPA transmission lines bisecting the Project Area on the north and south ends can be seen from this viewpoint. The quality of the views from this viewpoint along SR 141 was rated as moderate, reflecting the fact that the visible landscape is relatively common in the region and has average scenic value. The ridge line along Underwood Mountain, which is in the area of the Project, provides a degree of topographic interest when viewed with the other natural appearing features. The landscape visual scenic quality from this viewpoint is moderate.

**Viewer Sensitivity.** Traffic volumes along SR 141 are minimal and used for local traffic and recreational traffic in the summer months. Considering the distance of the Project from this viewpoint (less than 5 miles), the minimal use of the highway, and the portion of the Project that is visible from the viewpoint, the level of view sensitivity is considered low. This is based on the duration of the view from SR 141, the low level of residential viewers from this viewpoint, and the scenic quality rating.
Figure 3.9-1

Locations of Simulation Viewpoints

Whistling Ridge Energy Project
Conditional Use Permit Application
Figure 3.9-2

Residences with Visible Turbines

Whistling Ridge Energy Project
Skamania County, Washington
Viewpoint 3: Husum

**Scenic Quality.** This viewpoint captures the view from SR 141 northeast of the Project Area. This viewpoint would be the first view of the Project from travelers moving south into the Project Area. The viewpoint encompasses the northern portion of the Project from the highway, which is the closest viewing area from that vantage point. The foreground of the viewpoint is pastoral with a middle ground view of the hillsides and a background view of Underwood Mountain and the Project Area. The view is natural appearing with moderate to high levels of vividness, unity, and intactness in the foreground, middle ground, and background of the photo. The quality of the view from this viewpoint was rated moderately high because of the above-average quality and the unity of the man-made and natural features on the landscape.

**Viewer Sensitivity.** When considering the distance of the Project from this viewpoint (greater than 5 miles), the duration of the view (roadway travelers), the portion of the Project that is visible from the viewpoint, the viewer types (minimal residential/recreational), and the scenic quality rating, the level of visual sensitivity is considered moderate.

Viewpoint 4: Ausplund Road and Cook-Underwood Road (Scenic Area KVA)

**Scenic Quality.** This viewpoint captures the view from the Ausplund Road and Cook-Underwood Road where they meet and provide residential, agricultural, and forest management access to the area. These roads are connector and feeder roads that can be accessed from SR 14. This area is elevated from the Columbia River Gorge National Scenic Area but is within its boundaries. The area has a mix of uses including agriculture, forest management, and some recreation. The foreground from the roadway is an agricultural setting with middle and background views of forest vegetation and forest management areas. The view is natural appearing with moderate levels of vividness, unity, and intactness. The quality of the view from this viewpoint was rated moderate because of the average or typical views of this type in the Project Area.

**Viewer Sensitivity.** When considering the distance of the Project from this viewpoint (0.5 to 5 miles), the viewer types (roadway travelers), the portion of the Project that is visible from the viewpoint, the viewer types (residential/roadway), and the scenic quality rating, the level of visual sensitivity is considered moderate.

Viewpoint 5: Willard

**Scenic Quality.** This viewpoint captures the view from the small residential community of Willard. This area is accessible by a County road from SR 14 and used by residential and private forest management users. The view looks southeast into the Project Area and provides a panorama of the longest string of turbines. The foreground is a mixture of mixed conifer second growth stands and the middle ground is of mixed timber harvest openings and a transmission corridor. The background view is similar and the mixture of vertical and horizon lines and formations detracts from the overall vividness and unity of the view. The intactness of the views is moderated by the changes in line and form. The quality of the view from this viewpoint was rated moderately low to moderate.
**Viewer Sensitivity.** When considering the distance of the Project from this viewpoint (0.5 to 5 miles), the duration of the view (foreground screening), the portion of the Project that is visible from the viewpoint, the viewer types (minimal residential), and the scenic quality rating, the level of sensitivity is considered moderate.

**Viewpoint 7: Mill A**

**Scenic Quality.** This viewpoint captures the view from the old mill property west of the Project Area. This area is accessible from Willard Road and has a mixture of uses. The view looks northeast into the southern end of the A turbine string. The foreground view is obstructed by the vertical lines of transmission towers. The middle ground view is of transmission corridors and extensive timber harvest openings. Many of the residential views are partially screened from the valley floor. There is a visual discord with the man-made alterations. The vividness, unity, and intactness appear uninviting and of moderate to low visual quality. The scenic quality rating for this viewpoint is moderately low.

**Viewer Sensitivity.** When considering the distance of the Project from this viewpoint (0.5 to 5 miles), the duration of the view (foreground screening), the portion of the Project that is visible from the viewpoint, the viewer types (minimal residential), and the scenic quality rating, the level of sensitivity is considered moderate.

**Viewpoint 11: I-84 Westbound (Scenic Area KVA)**

**Scenic Quality.** This viewpoint captures the view from I-84 traveling westbound towards the Project Area from the east. I-84 travels along the Columbia River Gorge National Scenic Area and views along this portion of the highway are generally directed towards the river and the distant scenery. Beyond the foreground view of the highway and other corresponding structures the view is generally intact with average or above vividness, unity, and intactness. Viewers traveling along this corridor have multiple line-of-sight transitions, and this is considered to be average within those views. The scenic quality rating for this viewpoint was rated moderate.

**Viewer Sensitivity.** When considering the distance of the Project from this viewpoint (8–10 miles), the portion of the Project that is visible from the viewpoint, the viewer types (roadway), and the scenic quality rating, the level of sensitivity was rated moderate.

**Viewpoint 12: Koberg Park (Within Scenic Area)**

**Scenic Quality.** This viewpoint captures the view across the Columbia River from Koberg Park. The foreground view of the river is a complete composition indicative of the area and the middle and backgrounds have a high level of vividness, unity, and intactness. The railway line that bisects the view in the middle ground tends to blend into the scenery without distraction. This view is considered to be above average for the types of views that are throughout the Scenic Area. The scenic quality rating for this viewpoint was rated moderately high.

**Viewer Sensitivity.** When considering the distance of the Project from this viewpoint (8–10 miles), the portion of the Project that is visible from the viewpoint, the viewer types (recreational), and the scenic quality rating, the level of sensitivity was rated moderate.
**Viewpoint 13: I-84 Eastbound (Scenic Area KVA)**

**Scenic Quality.** This viewpoint captures the view from I-84 traveling eastbound towards the Project Area from the west. I-84 travels along the Scenic Area and views along this portion of the highway are generally directed towards the river and the distant scenery. Beyond the foreground view of transmission structures the view is generally intact with average or above-average vividness, unity, and intactness. Viewers traveling along this corridor have multiple line of sight transitions and this view is considered to be above average within the context of those multiple views. The scenic quality rating for this viewpoint was rated moderately high.

**Viewer Sensitivity.** When considering the distance of the Project from this viewpoint (3 to 5 miles), the portion of the Project that is visible from the viewpoint, the viewer types (roadway travelers with fleeting views), and the scenic quality rating, the level of sensitivity was rated as moderately low.

**Viewpoint 14: Viento State Park (Within Scenic Area)**

**Scenic Quality.** This viewpoint captures the view from Viento State Park, a popular recreation and rest area along the Columbia River. Landscape features are diverse and intact and the contrasts of the features have a high level of unity. This view is the open waters of the Columbia River in the foreground with rock features and vegetation in the middle ground and a background of mountains that provides an overall pleasing composition that is inviting to the viewer. This view is one of the less common views along the Gorge and has an above average scenic value. The scenic quality rating for this viewpoint was rated moderately high to high.

**Viewer Sensitivity.** When considering the distance of the Project from this viewpoint (greater than 5 miles), the portion of the Project that is visible from the viewpoint, the viewer types (recreational), and the scenic quality rating, the level of sensitivity was rated as moderate to high.

**Viewpoint 15: Frankton Road (Within Scenic Area)**

**Scenic Quality.** This viewpoint represents the view from the higher-elevation residential areas west of Hood River. The view looks across the Columbia River into the Project Area. Frankton Road is a local access road and traffic is considered low. Residences in this area have views both north and south. Many of the views are screened to the north and take advantage of the view south into Oregon. The view has residential development in the foreground, which is common along this roadway. The middle ground is vegetation, some agriculture, and some forest management. The background is the ridge along the Project Area. These types of views are relatively common and of average scenic value when compared to the broader area. Vividness, unity, and intactness are moderate to high levels. The scenic quality rating for these viewpoints is moderate.

**Viewer Sensitivity.** When considering the distance of the Project from this viewpoint (greater than 5 miles), the portion of the Project that is visible from the viewpoint, the viewer types (residential), and the scenic quality rating, the level of sensitivity was rated as moderate.
Viewpoint 17: Providence Hospital Hood River (Within Scenic Area)

Scenic Quality. This viewpoint represents the north view of the Project from the City of Hood River. The foreground is an urban setting with a middle ground of vegetation that screens the background to some degree, providing a diverse composition of features. The view has a somewhat vivid appeal based mostly on the man-made features; however, the unity and intactness are below average and are visually discordant. This detracts from the background view. Viewers would generally be more focused on the business of the urban environment. The scenic quality of these viewpoints was rated moderately low.

Viewer Sensitivity. When considering the distance of the Project from this viewpoint (more than 5 miles), the portion of the Project that is visible from the viewpoint, the viewer types (urban/residential), and the scenic quality rating, the level of sensitivity was rated as low.

Viewpoint 19: Columbia River Highway (Within Scenic Area)

Scenic Quality. This viewpoint represents the view of the roadway traveler on the Columbia River Highway (Highway 30) southeast of the Project Area. This view has a higher scenic quality and is more representative of the high-quality views within the Columbia Gorge area. The foreground, middle ground, and background all have an above average arrangement of spaces in the landscape. The view appears intact and has a unity with the road and even the transmission line that is visible in the middle ground. The landscape provides diversity but not to the extent of clutter. This view is rated moderately high for scenic quality.

Viewer Sensitivity. When considering the distance of the Project from this viewpoint (greater than 5 miles), the portion of the Project that is visible from the viewpoint, the viewer types (roadway travelers/sightseers), and the scenic quality rating, the level of sensitivity was rated as moderate.

Viewpoint 23: Ausplund Road End (Within Scenic Area)

Scenic Quality. This viewpoint represents the view from local area roadways at specific intersections where local area travelers might converge. These roads are old logging roads that have been upgraded to meet the local residential use. However, they are still used for logging and would be used in the construction portion of this Project. This would include upgrading and in some instances widening the roads, which can affect visual quality. This view is from the end of the Ausplund Road which would be used to access the area for construction and maintenance. Very few viewers beyond those associated with the Project would see this viewshed. Without the vehicles in the foreground, the scenic quality rating assigned to this view is moderate.

Viewer Sensitivity. When considering the distance of the Project from this viewpoint (less than 1 mile), the portion of the Project that is visible from the viewpoint, the viewer types (local area workers and residence), and the scenic quality rating, the level of sensitivity was rated as low to moderate.
3.9.3 IMPACTS

Visual impacts are a primary consideration for wind power projects. The alteration of the landscape by the introduction of wind turbines, and the visual impacts of wind turbines on the landscape is a complex issue, and factors other than the attributes described above play a major role in the observer’s reaction or perception of the visual impacts or change.

Wind turbines are relatively large, and being available to the wind requires the turbines to be in a location that is open and highly visible. Viewers’ reaction to the visual impacts of wind turbines on the landscape is a complex issue, and is influenced by the generally positive perception of wind as a renewable energy alternative. However, many supporters of renewable energy projects express a desire that the projects be placed elsewhere. This message was voiced by several people in the public scoping meetings for this Draft EIS. Studies have shown that some negative opinions change once the wind projects are constructed and in operation.

3.9.3.1 Proposed Action

The appearance of the Project is determined by the Project facilities that may be seen by the public during operation of the Project. Project facilities include turbines, a meteorological tower, the BPA substation, the Operations and Maintenance facility (at one of two alternative locations) and roads. The substation, Operations and Maintenance facility, and Project Area roads would be difficult to see from outside of the Project Area, and would be typical of development in this rural area dominated by forest management and large-scale agriculture. The meteorological tower is slender and would have no moving parts, and would not be as noticeable as a wind turbine. Consequently, the visual impact assessment focused on the potential impact of the turbines. This section describes Project facilities and their visibility from outside the Project Area.

The Project facilities are:

- **Turbines.** The turbines would be the most visible Project facilities. Commercial-scale turbines are similar in appearance and are composed of a tower, a nacelle, and turbine blades attached to a rotor. The tower would appear to be a steel pole, tapered from base to hub, with a base diameter of approximately 14 feet. At the top of and perpendicular to the tower, the nacelle would appear to be an elongated metal boxlike structure. Three aerodynamically shaped blades connected to a nose cone attach to the front of the nacelle. Depending on the turbine model chosen, each turbine would be up to approximately 426 feet tall (262-foot hub height and 164-foot radius blades, measured from the ground to the turbine blade tip), and would be mounted on a concrete foundation. Wind turbines would be grouped in “strings,” with each turbine spaced approximately 350 to 800 feet from the next (or approximately 1.5 to 2.5 times the diameter of the turbine rotor). Typically, wind turbines are painted white to comply with FAA daytime lighting requirements. A gravel buffer and crane pad would be maintained at each turbine site, and would not be visible from outside the Project Area.

The tall turbines would introduce vertical lines into the viewshed. Blades would be visible when stationary and moving at low speeds, but would not be visible when moving more quickly. The visibility of the turbines would be affected by the angle of the sun and
climate conditions. At low sun angles (morning and evening) sunlight would reflect off a greater surface of the turbine and result in greater visibility. Conversely, when the sun is directly overhead, a relatively small surface of the turbine would reflect. On cloudy days, visibility of the light-colored turbines would be less since the turbines would blend with the background. Available data indicates that on average, there are 145 sunny days per year in Skamania County, Washington, that is, 39.7 percent of days are sunny. Therefore, the majority of the time some clouds are present. The turbines would therefore blend with the background the majority of the year.

- **Electrical System.** The electrical system would primarily be underground, and would connect the turbines to the BPA substation. The substation would occupy a portion of a fenced 5-acre area at the southwest end of the Project Area, immediately adjacent to the BPA 230-kV transmission line. A 50-foot cleared area would be maintained around substation. The substation would difficult to see from outside the Project Area.

- **Operations and Maintenance Facility.** The Operations and Maintenance facility would be a 3,000 square foot metal building approximately 16 feet tall, with a gravel parking lot and surrounding fence and gated entrance. The facility would be built at one of two alternative locations, either in the Project Area or to the west of the site on West Pit Road. In either location the visual impact of the facility would be minimal, and similar to small utility or agricultural facilities in the area.

- **Roads.** The Project would require 7.9 miles of new permanent gravel roads, and 2.4 miles of improved existing roads. New permanent and improved roads would be visually similar to existing secondary and gravel roads in the Project Area and most would be difficult to see from outside of the Project Area.

- **Meteorological Tower.** The Project would include one meteorological tower, approximately 221 to 262 feet tall. The tower height would be the same as the hub height for the selected wind turbine. Because meteorological towers are slender and do not have large components like turbine blades, the meteorological tower would be difficult to see from outside the Project Area.

The primary visual concern is the potential impacts of the proposed installation of up to 50 wind turbines on existing views and the overall aesthetic character of the Project Area. The specific turbine type and manufacturer have not been selected; however, it is likely that the turbines would be in the 1.2- to 2.5-MW range, and would measure approximately 426 feet in height (262-foot hub height and 164-foot radius blades). Each turbine would have three rotor blades made of laminated fiberglass. The diameter of the circle swept by each blade would be from 264 to 320 feet, depending on which turbine was selected. Turbine “strings” would include rows of from three to 21 turbines placed at approximately 350 to 500 foot intervals.

22 See: http://www.bestplaces.net/County/Skamania-Washington.aspx#.
For many viewers, the location of the Project would minimize visual impacts. Location effects include the limiting effect of topography, tree cover, the relatively long distance to surrounding residences, and the orientation of the Project vis-à-vis viewers. Figure 3.9-2 shows the number of turbines visible from residences and a selection of local businesses. The figure does not attempt to show all businesses in the Project Area; the businesses added are for general reference. The figure shows that the Project would not be visible from many of the residences to the southeast of the Project, and would be most visible to residences to the west, in and around Mill A. This figure may overstate the visibility of the Project somewhat, for two reasons:

- Turbines are judged to be visible if any part of the turbine blades would be visible. In practice, if only the tip of a blade is visible then viewers would not see it when it is not vertical or when the blade is moving.

- The visual simulation is based on topography alone, and does not take into account the masking effect of trees.

However, public input and comments during EIS scoping indicated that for some viewers, the presence of the wind turbines represents a negative impact because it alters the appearance of the rural landscape over a large area. The flashing of aviation warning lights on the tops of turbines at night would similarly be considered a negative impact.

The visual impact assessment was based on evaluating the changes to the existing visual resources that would result from construction and operation of the Project. These changes were assessed, in part, by evaluating the “after” views provided by the computer-generated visual simulations and comparing them to the existing visual environment. Consideration was given to the following factors in determining the extent and implications of the visual changes:

- Changes in the affected visual environment’s composition, character, and valued qualities

- The affected visual environment’s context, including distance

- The extent to which the affected environment contains places or features that have been designated in plans and policies for protection or special consideration

- The number of viewers, their activities, and the extent to which these activities relate to the aesthetic qualities affected by the changes

- The distance factor was considered in the sensitivity rating for establishment of baseline and therefore becomes a factor in the impact assessment

Levels of impact were classified as high, moderate, and low:

- **High.** High levels of impact were assigned when turbines would be highly visible in areas with a high number of sensitive viewers, and would greatly alter levels of vividness, unity, and intactness, decreasing the level of visual quality. This is the largest number of viewers from that key viewpoint. The assessment accounts for the number of viewers and would add that into the discussion.
• **Moderate.** Moderate levels of impacts were assigned in situations when turbines would be visible in areas with moderate levels of visual sensitivity and viewers, where the presence of the turbines would moderately alter levels of landscape vividness, unity, and intactness.

• **Low.** Low levels of visual impact were found in situations when the Project would have relatively small effects on overall landscape level attributes, where existing levels of landscape aesthetic quality are low, or where there are low levels of visual sensitivity and a low number of viewers.

While only three levels of impact (High, Moderate, and Low) were used to describe the visual impacts of the Project on each viewpoint, it should be noted that each of these impact levels is based on the consideration of six levels of landscape visual quality (Outstanding, High, Moderately High, Moderate, Moderately Low and Low) and three levels of visual sensitivity (Low, Moderate and High) when determining the final anticipated level of visual impact. This approach, a result of the combined use of the FHWA/USFS methodology provides a credible explanation of how the proposed Project would affect each viewpoint by describing the contrast between pre- and post-project conditions as seen from the different viewpoints, by different viewer groups, and from different distances.

**Construction**

During construction, large earth-moving equipment, trucks, cranes, and other heavy equipment would be visible from some nearby areas. At times, small, localized clouds of dust created by road building and other grading activities may be visible at the site. Because of construction-related grading activities, areas of exposed soil and fresh gravel that contrast with the colors of the surrounding undisturbed landscape would be visible.

In close-up views the changes associated with the construction activities would be highly visible and would have a moderate to high visual impact. Close-up views would include those seen by travelers on the segment of the local roads that pass around the Project Area and those seen from the closest residences. From more distant locations, the visual effects of construction would be relatively minor and would have little or no impact on the quality of views.

Construction impacts would be short-term, lasting no more than the one-year construction period.

**Operation**

During Project operation, the turbines would be visible from some viewpoints. The potential level of visual impacts from key and representative Project viewpoints is summarized in Table 3.9-2 and shown on Figures 3.9-3 through 3.9-15. Additional viewpoints are analyzed in Section 4.2-3 of the Application for Site Certification (Appendix A). A more detailed description for each viewpoint follows the summary table and figures. The visual impact analysis showed that the Project has the potential to create low to moderate levels of visual impact at key viewpoints.

Wireline
Viewpoint 1: Pucker Huddle (Figure 3.9-3)

From Viewpoint 1, approximately 25 turbines would be visible on the ridge tops at distances of approximately 4 miles to the nearest turbines. At the distance depicted in the photo, the visual clutter of more turbines has more impact than the considerable scale of the larger turbines. The composition would be silhouetted against the sky, increasing their visual impact. However, the distance and the line of sight from the residential areas would minimize the contrast. The presence of the turbines would reduce the scene’s degree of intactness by introducing a large number of highly visible engineered vertical elements.

The potential visual impact from Viewpoint 1 would range from low to moderate.

Viewpoint 3: Husum (Figure 3.9-4)

From Viewpoint 3, approximately 27 turbines would be visible on the ridge tips at a distance of approximately 4.75 miles to the nearest turbines. Figure 3.9-4 illustrates the simulated views from SR 141 traveling south into the Project Area. Travelers moving along this highway are generally using the road to access recreation areas or for leisurely drives. Residential viewers would be screened to some degree from the view based on vegetation, landscaping, and the line of sight from the valley floor. Introduction of these vertical structures in the background of this view would decrease the intactness of the landscape, based on the numbers of turbines that would be visible. The composition of the view would be altered with the introduction of these engineered structures and would be apparent on the horizon to the travelers and residence in the area.

Due to the low levels of viewers, duration of the views, and viewer awareness, the visual impact from Viewpoint 3 is considered moderate.

Viewpoint 4: Ausplund Road and Cook-Underwood Road (Figure 3.9-5)

From Viewpoint 4, approximately 14 turbines would be visible looking northwest from the roadway, at a distance of approximately 1.23 miles to the nearest turbines. Figure 3.9-5 illustrates the simulated view from the roadway at the intersections of Ausplund and Cook-Underwood Roads. Because of the position of this viewpoint (direct line of sight) and its distance from the turbines, the turbines apparent scale would be visible and apparent. The presence of the turbines would likely have a moderate effect on the vividness of the existing view and a moderate impact on the overall sense of unity and intactness by the roadway and residential viewers.

The potential visual impact from Viewpoint 4 would be moderate.

Viewpoint 5: Willard (Figure 3.9-6)

From Viewpoint 5, approximately 24 turbines in turbine strings A and B would be visible from screened views from residences in the area of Willard. Figure 3.9-6 shows the simulated view from Viewpoint 5 in the northern portion of the Project looking southeast. These turbines would be located in the ridge tops, with the nearest turbines approximately 1.35 miles away. Because the turbines would be seen against the sky at medium range and screened in many residential views, they would still be visible in the background. This would reduce the visual unity and
intactness minimally when compared to the existing components in the landscape. The wind turbines would be arrayed uniformly along the ridgeline and would create a moderate change in the setting’s existing low to moderate visual quality.

The potential visual impact from Viewpoint 5 would be moderate.

**Viewpoint 7: Mill A (Figure 3.9-7)**

From Viewpoint 7, approximately 35 turbines in strings A and B would be visible in the foreground, middle ground, and background of this view. The nearest turbines would be located approximately 1.62 miles away. Figure 3.9-7 shows the simulated view. The turbines would be seen against the sky. The presence of the long line of turbines may create a slight increase in the vividness of this view. The unity of the view would be decreased further by the long turbine line and the intactness of the view would be moderately compromised compared to the existing view.

The potential visual impact from Viewpoint 7 is considered to be low to moderate.

**Viewpoint 11: I-84 Westbound (Figure 3.9-8)**

From Viewpoint 11, approximately 19 turbines would be visible in the distance background to roadway travelers looking west into the Project Area from I-84. The nearest turbines would be 8.39 miles away. Figure 3.9-8 shows the simulated view. Although the turbines would be visible to travelers on the far horizon, their presence is not expected to decrease the existing quality of this view, because of their relatively small size at this viewing distance. The visible turbines would have a minimal effect on this view’s vividness, unity, and intactness.

The potential visual impact from Viewpoint 11 was rated as moderate to low.

**Viewpoint 12: Koberg Park (Figure 3.9-9)**

From Viewpoint 12, approximately 17 turbines would be visible in the distant background to recreational users of the park and river. The nearest turbines would be approximately 6.60 miles away. The view looks west into the Project Area. Figure 3.9-9 shows the simulated view. Although the turbines would be visible to the viewers on the far horizon it is not expected to decrease the existing quality of this view to a great degree, because of their relatively small size at this viewing distance. The visible turbines would have a minimal effect on this view’s vividness, unity, and intactness.

The potential visual impact from Viewpoint 12 was considered to be moderate.

**Viewpoint 13: I-84 Eastbound (Figure 3.9-10)**

From Viewpoint 13, approximately eight turbines would be visible in the background to travelers on the roadway looking west into the Project Area from I-84. The nearest turbines would be approximately 3.43 miles away. Figure 3.9-10 shows the simulated view. This view for travelers would be of short duration. Although the turbines would be visible to travelers on the horizon it is not expected to decrease the existing quality of this view because of the number of turbines visible and the partial screening from the middle ground ridgeline. The visible turbines would have a minimal effect on this view’s vividness, unity, and intactness for these reasons.
The potential visual impact from Viewpoint 13 was rated as moderate to low.

**Viewpoint 14: Viento State Park (Figure 3.9-11)**

From Viewpoint 14, approximately 20 turbines in the background would be visible to the recreational users of the area. The nearest turbines would be just under four miles away. Figure 3.9-11 shows the simulated view. Although the water-related recreational activities would have the line of sight more related to the water and river banks, the recreational users moving through this area would be affected by this contrast in the view. The vividness of the scenic quality may be positively or negatively affected, depending on the user perception of turbines in the background. The unity and intactness of the existing view would be moderately compromised and the visible turbines would have a moderate effect on the view’s scenic quality compared to existing conditions, due to the distance from the park and activities in the foreground and middle ground.

The potential visual impact for Viewpoint 14 was considered to be moderate.

**Viewpoint 15: Frankton Road (Figure 3.9-12)**

From Viewpoint 15, approximately 10 turbines can be seen, with the nearest turbines approximately 4.51 miles away. Figure 3.9-12 shows the simulated view. At this distance, the contrast would have a minor effect on the overall visual impact. Consequently, because the prominence of the turbines in the view would be low, the turbines would have a minor effect on the vividness, unity, and intactness from this viewpoint.

The potential visual impact from this viewpoint would be moderate.

**Viewpoint 17: Province Hospital Hood River (Figure 3.9-13)**

From Viewpoint 17, only two turbines can be seen, and they are diminished by the distance (just over five miles). Figure 3.9-13 shows the simulated view. At this distance, viewers would have to scan the horizon to find the turbines. Consequently, minor effect or negligible effects to the scenic quality is expected.

The potential visual impact from this viewpoint would be low.

**Viewpoint 19: Columbia River Highway (Figure 3.9-14)**

From Viewpoint 19, approximately nine turbines are visible in the distant background. The nearest turbines would be approximately 6.46 miles away. Figure 3.9-14 shows the simulated view. Although the turbines would be visible in the background the viewer would have to have a focused orientation to see them in the landscape. The amount of turbines and the limited prominence based on the distance is expected to have a minimal effect on the scenic quality from this viewpoint.

The potential visual impact from this viewpoint would be low.

**Viewpoint 23: Ausplund Road End (Figure 3.9-15)**

From Viewpoint 23, approximately eight turbines can be seen. The nearest turbine would be approximately 0.64 mile away. Figure 3.9-15 shows the simulated view. This area would be
within one mile of the Project and the turbines would be highly visible at the end of this road. However, very minimal use of these roads beyond workers associated with forest management reduces the viewer types. Regardless, the impacts of the turbines on the landscape would affect the scenic quality of the view.

The potential visual impact from this viewpoint would be moderate.

**Viewpoint 24: Dog Mountain**

Because the Project Area cannot be seen from the Dog Mountain trail (either during the day or at night), no simulated view was prepared. There would be no impact.

**Night Lighting**

The Project would be required to comply with the Federal Aviation Administration aircraft safety lighting requirements for structures greater than 200 feet tall, which includes turbines and meteorological towers. The exact number of turbines that would require lighting would be specified by the Federal Aviation Administration after final Project plan review; however, current guidance requires that warning lights be mounted on the first and last turbines of each string, and from those end turbines, lights should then be positioned such that the next lit turbine is no more than 1/2 mile, or 2640 feet, from the last lit turbine. The lights would be synchronized to flash together to illuminate the full extent of the Project Area (Patterson 2005). These lights would be visible as small blinking points of red light; they would not light up the sky or the surrounding landscape. Aside from any required aircraft warning lights, the turbines would not be illuminated at night. There would be one meteorological tower located within the Project Area. Its location would be selected during the micro-siting process. Depending on its proximity to turbine towers, it may or may not require aircraft safety lighting.

The Draft EIS for the Nine Canyon Wind Project contains a generic illustration of night lights and can be found online at http://www.efsec.wa.gov/wildhorse/deis/figures/40%20Fig%203.10-9%20and%2010.pdf.

**Columbia River Gorge National Scenic Area**

During scoping, some commenters expressed concern that Project operation would impact the Scenic Area adversely since turbines would be visible from some Key Viewing Areas inside the Scenic Area. Analysis of KVAs and viewpoints within the Scenic Area were sought and analyzed. The presence of the Project would cause low to moderate visual impact to viewpoints within the Scenic Area.

Congress has determined that the National Scenic Act is not to be used to regulate activities outside of the Scenic Area boundary. The Act states that “*(a) Nothing in this Act shall ... (10) Establish protective perimeters or buffer zones around the scenic area or each special management area. The fact that activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management area.*” no protective perimeters or buffer zones shall be established around the scenic area or each special management area. Activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard.
from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas (16 USC § 544O(a)(10). This federal policy and Congressional mandate discourage projecting National Scenic Act policies, regulations and directives beyond the boundary of the Scenic Area.

**Project Decommissioning**

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. A detailed site restoration plan is required within ninety days of Project decommissioning. The initial site restoration plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is suspended or terminated during construction or before it has completed its useful operating life. The initial site restoration plan would include or parallel a decommissioning plan for the Project. Visual and aesthetic impact from decommissioning would be similar to those expected during the construction phase.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major visual resource issues presently anticipated. If impacts to visual resources are anticipated to occur as a result of site restoration and project decommissioning, mitigation measures would be proposed as part of the plan.

**3.9.3.2 No Action Alternative**

Under the No Action Alternative, turbines would not be built. Existing visual conditions would continue unchanged, and would be influenced primarily by ongoing timber harvest until and unless a different applicant proposed to develop the wind energy potential of the area. In the event the failure to construct this Project results in continuation and expansion of fossil fuel energy generation sources, it is foreseeable that air quality, including haze conditions, would continue to be a negative impact to the air quality and scenic resources of the Columbia River Gorge National Scenic Area.

**3.9.4 MITIGATION MEASURES**

The following mitigation measures are identified to avoid, minimize, and compensate for potential visual resource impacts during construction and operation of the proposed Project to the extent feasible.

- Ensure that a non-reflective flat neutral gray or light color is the choice of color for the turbines so that visual impacts would be minimized. The primary mitigation measure available for visual impacts is the choice of color for the turbines. Although a brown turbine color would reduce visual contrast in views where the turbines are seen against the landscape, it would also accentuate the visibility of the turbines where they would be seen against the sky. In addition, the brown color would have a greater contrast when snow is on the ground. Because the turbines are most frequently seen against the sky, particularly in close-range views where visual concerns are the greatest, a non-reflective flat neutral gray or light color would be ideal.
• Comply with Federal Aviation Administration requirements for safety lighting. Lights typically used to meet Federal Aviation Administration requirements would to some extent be shielded from ground level view due to a constrained (3–5 degree) vertical beam. The Federal Aviation Administration would independently review the lighting of individual turbines during the micrositing process and consult on mitigation. However, the Project must comply with the safety lighting requirement.

3.9.5 UNAVOIDABLE ADVERSE IMPACTS

The Project would cause some visual impact to surrounding areas where turbines were visible, including some areas inside the Columbia River Gorge National Scenic Area. However, the visual impact analysis showed that the anticipated level of visual impact would not be higher than low to moderate at any of the viewpoints examined.

3.9.6 REFERENCES

3.10 HISTORICAL AND CULTURAL RESOURCES

This section describes existing historical and cultural resources in the Project vicinity and identifies potential impacts to these resources from construction and operation of the proposed Project. Cultural resources include buildings, sites, structures, and objects, each of which may have historical, architectural, archaeological, cultural, or scientific importance. Artifacts, records, and material remains associated with these properties, and traditional cultural properties, which can include archaeological, traditional procurement, and religious sites and landscapes, are types of cultural resources.

The primary source of information for this section is the Cultural Resources Inventory Report prepared in support of the Application for Site Certification by URS (2009), as supplemented by fieldwork done by URS in December 2009 (URS 2010). The Cultural Resources Inventory Report was designed to identify, evaluate, and record pre-contact and historic cultural resources.
URS did so in accordance with Chapter 36 CFR §800 of the National Historic Preservation Act (NHPA) which is the regulatory requirement for the BPA Project Area as noted in Section 1.2.2. BPA’s Project Area would be limited to the location of its proposed substation at the point of interconnection. The survey also was designed to fulfill the Applicant’s SEPA requirements for their portion of the Project, the wind facility itself. The survey objectives include identifying archaeological resources and historic properties that might be considered eligible for the National Register of Historic Places (NRHP) located within the area of potential effects (APE) for the proposed Project for both BPA’s interconnection and the Applicant’s wind facility.

3.10.1 REGULATORY SETTING

3.10.1.1 Laws and Regulations

Several federal and state laws protect cultural resources, including NEPA and SEPA, which require that impacts of federal and state actions on cultural resources be identified and assessed in environmental documents, as well as the National Historic Preservation Act (NHPA), which establishes a national policy of historical preservation and requires that the effects of Federal actions (such as BPA’s interconnection with the Project) on significant cultural resources be determined. Collectively, these regulations and guidelines establish a comprehensive program for the identification, evaluation, and treatment of cultural resources.

To be eligible for the National Register of Historic Places (NRHP), properties must be at least 50 years old (unless they have special significance) and have national, state, or local significance in American history, architecture, archaeology, engineering, or culture. They also must possess integrity of location, design, setting, materials, workmanship, feeling, and association, and meet at least one of four criteria:

- **Criterion A**: be associated with important historical events or trends;
- **Criterion B**: be associated with important people;
- **Criterion C**: have important characteristics of style, type, or have artistic value;
- **Criterion D**: have yielded or have potential to yield important information.

If a resource is determined eligible for the NRHP, then Section 106 of the NHPA (80 Stat. 915; 16 USC 470) and its implementing regulations (36 CFR 800) require that effects of the proposed federal project to that resource be assessed. If a property eligible for the NRHP would be adversely affected by the proposed federal action, the federal agency must evaluate alternatives or modifications to the proposed action that would avoid, minimize or mitigate adverse effects.

3.10.1.2 Area of Potential Effect

The NHPA requires that the Area of Potential Effect (APE) for the Project Area be determined. As a federal law, the NHPA requires federal agencies to evaluate the impact of all federally-funded or permitted projects on historic properties (buildings, archaeological sites, etc.) through
the Section 106 review process. This process applies only to BPA’s portion of the Project (the interconnection). However, the DEIS included an APE for the entire Project Area. Figure 3.10-1 has been updated to show the BPA’s APE and the Applicant’s APE. For BPA, the APE is the proposed substation site--a 5 acre plot and several steel lattice and wood pole structures located towards the southern end of the Applicant’s Project Area. As part of the Section 106 review process, the Washington Department of Archaeology and Historic Preservation (DAHP) concurred with BPA’s definition of BPA’s proposed APE on August 9, 2010 (see Appendix E).

The proposed Project has the potential to affect cultural resources and as such an APE was identified (the Applicant’s APE). The APE for direct effects to cultural resources is considered to be the footprint for potential ground-disturbing activities that are anticipated to occur during construction and long-term maintenance of the Project. For the Project, ground disturbance could take place in the turbine string corridors, road corridors inside the Project Area, the West Pit Road outside the Project Area, overhead and underground transmission corridors inside the site Project Area, the Operation and Maintenance facility (two alternative sites), and the substation and lay-down areas. These activities have a total footprint of approximately 379 384 acres (Figure 3.10-1) and constitute the APE for the Applicant’s direct effects to cultural resources. The Applicant’s indirect APE is the area outside of the Project boundary where the Project may have, for instance, a visual impact on significant cultural resources. DAHP concurred with EFSEC’s definition of the APE for the Applicant on February 1, 2010 (see Appendix E).

3.10.2 AFFECTED ENVIRONMENT

3.10.2.1 Cultural Context

*Pre-Contact Background*

The archaeological record of the Columbia Plateau documents the prehistory of a region that is distinguished by local adaptations to a unique set of resources and its inland maritime environment (Chatters and Pokotylo 1998). Archaeological research near the site has focused principally within the Columbia River corridor, and models for the Portland Basin of the Northwest Coast culture area (Pettigrew 1981), the Columbia Plateau culture area (e.g., Galm et al. 1981), and the White Salmon and Klickitat rivers specifically (Masten and Galm 1989) can be applied. An overview of archaeological research within the Columbia River Gorge has been summarized by Beckham et al. (1988). Recently, Griffin and Churchill (2001) synthesized the multiple cultural chronologies that have been posited for the region; the following discussion is based on their synthesis.
Figure 3.10.1
Area of Potential Effects

Whistling Ridge Energy Project
Skamania County, Washington
The Early period dates from 11,000 to 4,500 years BP, though recent studies at Paisley Caves in Oregon suggest an even earlier date of regional occupation at least by about 14,300 BP (Jenkins 2009). A mobile lifestyle focused on intensive riverine resources with periodic use of uplands is inferred. Subsistence shifted from reliance on large game to an increase in the importance of fish, root, and vegetable resources by the end of the period. Permanent structures are not found in association with the earliest sites, but semi-subterranean house settlements appeared along major rivers at the latter stage, reflecting an increase in sedentism. Sites dating to this period have mostly been found around The Dalles at the eastern end of the Columbia River Gorge (Griffin and Churchill 2001).

The Middle period occurred from approximately 4,500 BP to 250 years BP and is characterized by increased occurrences of semi-subterranean houses and the appearance of food storage facilities, indicative of further sedentism and decreased mobility. Concurrently, there was intensification of use of fish, roots, and vegetable resources during the first half of the period, with hunting of secondary importance. The pattern of winter sedentism was apparently established during this period. There are more archaeological sites, including villages, fishing camps, and hunting camps that date to this period and that are found in the area between the Cascade Mountain Range and the town of Lyle, as well as The Dalles area (Griffin and Churchill 2001).

The Late period, dating from 250 to 100 years BP, is defined by the appearance of the horse on the Columbia River Plateau (circa 1730s), which increased the mobility and resource acquisition patterns of local groups. The period is also marked by the introduction of trade goods and the devastating effects of introduced diseases on the local populations, as well as the arrival of Euro-Americans. There is an increase in the quantity and distribution of sites dating to this period, with most being located along the confluences of major rivers and the Columbia River, though several sites are found on sandy terraces as well as within the islands. A large number of historic villages were noted by Lewis and Clark between Beacon Rock and The Dalles during their 1805–1806 travels (Griffin and Churchill 2001).

Along the lower White Salmon River, Middle and Late period projectile point styles are common. Recorded site types in this area include housepit villages, temporary camps, petroglyph sites, and cemetery sites (Griffin and Churchill 2001).

**Ethnographic and Ethnohistoric Background**

The proposed Project Area is located near the boundary between two ethnographic culture areas of the Pacific Northwest, the Northwest Coast, and the Columbia Plateau. Local groups living in the Columbia River Gorge at the time of historic contact are known from the languages they spoke as the Upper Chinookans and the Echeesh-Keens (Sahaptins)23 (Beckham et al. 1988; Griffin and Churchill 2001). In the general area of the Project, the Columbia River Gorge was

---

23 Griffin and Churchill (2001) note that the Yakama Nation prefers the use of “Echeesh-Keen” over the term “Sahaptin.”
used by the Eastern Chinookan-speaking Wishram, White Salmon, and Cascades people, as well as the Echeesh-Keen-speaking Yakama and Klickitat (Griffin and Churchill 2001).

The Upper Chinookans occupied the Gorge from the vicinity of the mouths of the Sandy and Washougal rivers east to the Deschutes River. Various Echeesh-Keen speaking groups lived to the east, including the Tenino, Klickitat, Yakama, and Umatilla. The Yakama primarily occupied territory north of the Tenino, while the Klickitat occupied inland regions to the northwest, extending to the Columbia River in the vicinity of the Klickitat River, along with Wishram peoples (Beckham et al. 1988, French and French 1998). Of these groups, the Project Area falls within territory that would have probably been used most intensively by the White Salmon, who comprised several small bands residing primarily in an area extending from about ten miles below The Dalles to the White Salmon River area, especially at the mouth of this river, although they lived away from the river as well (Ruby and Brown 1992).

During the nineteenth century, White Salmon usage most notably overlapped with the Klickitat, the Echeesh-Keen-speaking group primarily occupying the upper drainages of the Klickitat and White Salmon rivers. Several villages were found at the mouth of the White Salmon River, including at least one that was shared with the Klickitat (French and French 1998, Ruby and Brown 1992, Spier and Sapir 1930). White Salmon winter villages were found upriver along the White Salmon near the contemporary communities of Husum and BZ Corner, and along Rattlesnake Creek to the north (Griffin and Churchill 2001). Use of Namnit (45SA22), an important ethnohistoric period fishing village at the mouth of the White Salmon River, continues into the present.

Less information appears to be available in the historic record regarding traditional use of the Little White Salmon River west of the White Salmon River. Another important village site was situated at the mouth of the Little White Salmon River: SkatxImmax, or ‘eating place,’ and sqtdalpt, or ‘it keeps tearing out’, both refer to the village located at modern-day Cook along the Columbia River (French and French 1998). Salmon came to spawn here, and in winter whitefish could be taken from the spawning pools (Nielsen 1959). A trail from Drano Lake traversed the east side of the river into the upper valley. Two main huckleberry fields, including Big Huckleberry Mountain on the south side of the lava beds and Little Huckleberry Mountain towards the headwaters of the Little White Salmon River, were frequented. Bark was peeled from many cedar trees along this trail for use in basket making. The racetrack near Red Mountain was the location of a big annual social event held in conjunction with the berry picking and drying (Nielsen 1959).

The Upper Chinookan and Echeesh-Keen peoples followed a similar seasonal pattern of subsistence activities, except that the former relied more heavily on fish than the latter (Griffin and Churchill 2001). In winter, limited hunting and fishing took place but subsistence was based on stored foods. With the arrival of the spring Chinook salmon, people would gather roots in the nearby hillsides. After the snow packs melted away, movement into the uplands occurred since fishing sites were usually inundated. Dried roots would then be hauled to the winter villages for storage in semi-subterranean cellars. Important spring gathering areas included Camas and Panakanic prairies, Deadhorse Meadow, and the Snowden area. Following the spring root gathering, people returned to the fishing areas along the major rivers to fish for blueback and
Chinook salmon, and women would gather golden currant, gooseberry, dogwood, service berry, and choke cherry from the river and nearby uplands. A type of tobacco was planted and harvested by Chinookans (French and French 1998). In late summer and early fall, huckleberries were picked in the uplands near Mt. Adams, and hunting for deer and elk occurred. Toward late fall, the winter villages would be reoccupied. The White Salmon River was a focal area for tule salmon harvested in the fall that attracted many families to the region (Griffin and Churchill 2001, Norton et al. 1983, Schuster 1998, Winthrop and Meninick 1996). The fishing village at the mouth of the White Salmon River also functioned as a minor trading center (Griffin 2001).

In sum, the ethnographic and ethnohistoric context indicates that the Project Area is situated along a high-elevation ridgeline about two to three miles from two ethnographic riverine village sites, and within approximately one mile of the Little Salmon River valley, which would have formed a natural travel corridor providing access from the Columbia River to upland regions to the north, such as the popular berry picking grounds in the Mount Adams country. No specific reference to the promontories that are in or near the Project Area, now known as Chemawa Hill or Underwood Mountain, were encountered in the reviewed literature, but proximity to known village sites suggests these high places and the adjacent ridgelines composing the Project Area could have been visited occasionally for non-residential, transient uses such as for spiritual activities, burials, or resource acquisition activities related to hunting, cedar peeling, plant gathering, and berry picking.

**Historic Background**

The first white pioneers to settle the section of the Columbia River between the Cascades and the confluence of the Snake River were reportedly the Joslyn family, who arrived at the White Salmon flats in 1852 and attempted to purchase their lands from the local Klickitats, in addition to filing a Donation Land Claim (McCoy 1987). Increased settlement by whites led to the creation of reservations throughout the region during the 1850s. Fourteen tribes and bands were signatories to the Yakama Treaty of June 9, 1855, when the Yakama ceded around 11 million acres to the US Government, while retaining rights for hunting, fishing, and gathering at traditional locations, and agreed to the establishment of the 1.3 million-acre Yakama Reservation. The White Salmon Reservation was temporarily established at the mouth of the White Salmon River at the Joslyn claim in 1856 for around 800 Native peoples who were not active in the Yakima War of 1855–1856, during which time a coalition of interior tribes led by Kamiakin fought against the US Army and local settlers. At the end of the war two years later, the White Salmon Reservation was closed and residents were removed to the Yakama Reservation. Some avoided relocation and claimed lands their families had traditionally used, including around Northwestern Lake and along the area’s minor drainages such as Buck Creek. Although a few took up farming, most continued to practice traditional subsistence activities at traditional places such as the Underwood In Lieu Site (Griffin and Churchill 2001).

The Underwood town site, located about six miles southeast of the Project Area and along the Columbia River, was among the earliest of the pioneer settlements in this portion of the Columbia River Gorge. Amos Underwood was a contemporary of the Joslyns who arrived in the region in 1852 and married Chief Chenowith’s daughter, Ellen. In 1861, Amos and Ellen Underwood built a log house at the site of the present town bearing their name, as well as a dock
and pier to accommodate sternwheelers. Amos’ brother Edward Underwood also settled here and his house reportedly served as an Indian gathering place, especially in the fall during the salmon runs on the White Salmon River (Thun 1959). The Underwood brothers platted a town site in 1904, in anticipation of growth related to the construction of the Spokane, Portland, & Seattle Railway beginning the following year (McCoy 2003).

The upper drainage of the Little White Salmon River Valley, including the location of the proposed alternate site for the Operations and Maintenance facility along Willard Road, was not homesteaded until the 1880s and 1890s, when the more desirable lower-elevation lands had already been taken (Thun 1959). There were a reported 35 homesteads from Cooks to the present day Oklahoma park at the head of the river (Nielsen 1959). A review of late-nineteenth century General Land Office maps (BLM 2009a) dated 1876 does not depict any settlement or other features of historic interest in or near the Project Area.

The history of the White Salmon and Little White Salmon region has a long association with the logging industry. Initially, the Menominee Lumber Company cut the easily-accessible timber into logs that could be floated down the White Salmon River. Oxen and horses were used to drag the timber, which traveled across several constructed rollaway dams before reaching the Columbia River, where they were rafted for towing to the Hood River mill (McCoy 1987). Wind River Lumber Company succeeded Menominee, using their dams along the White Salmon as they removed virgin timber from the Buck Creek, Mill Creek and Underwood Mountain areas (McCoy 1987). It was at this time that the upland forests of the Project Area were probably first harvested.

As of 1896, there were seven sawmills operating in Skamania County, the most notable of these being the Oregon Lumber Company’s along the Little White Salmon River (Price 1896). After the logging of Underwood Mountain was complete, the Oregon Lumber Company established the Mill A sawmill and headquarters along the west side of the Little White Salmon River, and another sawmill at Chenowith Flat on the east side of the Little White Salmon River at what was known as Mill B (less than one mile to the south of the proposed Maintenance Yard Alternative Location at Willard Road) (Attwell 1975, McCoy 1987). There were flumes on both sides of the river that carried the lumber to the Columbia (Atwell 1975). When the supply of timber became more difficult to access, the company closed the mill in 1907, and moved it to Oregon (McCoy 1987, Nielsen 1959, Thun 1959).

Broughton Lumber Company was established around 1916 by Harold Broughton and D.M. Stevenson, who operated a mill at Willard along the Little White Salmon River. Using water diverted from the Little White Salmon River, Broughton Lumber Company transported the timber via a flume connecting the mill at Willard to the Columbia River, and then rafted the logs across the river to Oregon for railroad transport. The flume originally consisted of a 4.5-mile long segment from Willard to Drano Lake, and was constructed by the Drano Flume Company around 1913. In 1923, Broughton purchased the Drano Flume Company and expanded their operation by building an additional 4.5 miles of flume from Drano Lake eastward along the Columbia River to a new resaw and planing mill located along the railroad near Underwood (McCoy 1987, Thomas 2007). Following its completion, boards could travel the nine-mile long flume to the planning mill in less than an hour.
From 1923 to about 1940, Broughton Lumber Company constructed and operated a railroad for transport of logs to the primary mill. Two steam engines were used and a maximum of nine miles of track that were laid to haul timber from the woods to the mill at Willard, but the tracks had no permanent location, as they were moved and re-laid as necessary. The Broughton Lumber Company operation closed in 1986, and portions of the flume from Willard to the Columbia River were dismantled by the company shortly thereafter (Thomas 2007).

The logging activity that cleared extensive areas on Underwood Mountain in the early-twentieth century opened up these lands for orchard use at the same time. Settlement occurred quickly as a result of the “Apple Boom,” the period between 1905 and 1920 when vast orchards were planted along the White Salmon Valley, on Underwood Mountain, and elsewhere throughout the region. In 1908, the completion of the railway across the north shore of the Columbia River contributed to this influx of residents. White Salmon emerged as a main trading center by 1910, and fruit packing plants were established along the railway (McCoy 1987 and 2003).

Land patents were filed relatively late, from 1905 to 1910, for the high elevation ridgelines that characterize most of the Project Area (BLM 2009b). The correlation of the land patent dates with the regional orchard boom and railroad completion date in the Project Area is suggestive of prospective claims either for orchards or as investments for lumber resources. It has not been determined how many of the early-twentieth century claimants actually resided on their parcels.

A 1929 USGS Hood River topographic quadrangle depicts the presence of one residential structure, an access road, and a trail within the Project Area.

Orchard growers at Underwood initially attempted to irrigate their crops with water pumped from the White Salmon River, but when the pump house was washed away by a flood, they attempted to take water out of Little Buck Creek using a gravity flume until the flume burned. Irrigation was not restored, and some orchard growers and farmers lost their land by foreclosure due to inability to pay taxes. A hard freeze in 1919 killed many apple trees, and several growers switched to winter pear crops (Thun 1959). Commercial orchards generally failed in the White Salmon Valley due to dry land and lack of organized irrigation, severe winters, and a short growing season at higher elevations. Many orchards were simply abandoned and reclaimed by second-growth timber (McCoy 1987 and 2003).

Improvements in transportation along the north shore of the Columbia River occurred after the 1919 opening of the North Bank Highway, especially when the five tunnels west of Underwood were completed in 1937. The Hood River to White Salmon Bridge was opened in 1924 (McCoy 2003), further connecting the economies of the two towns.

3.10.2.2 Cultural Resources Overview

Tribal Consultation and Traditional Cultural Resources

Based on the archival review, no specific traditional cultural properties or sacred sites are documented within the Project Area. Given that this information is culturally sensitive, however, the reviewed records are not likely to contain specific references to traditional or sacred sites that could occur within the Project Area and tribal consultation is required to address their potential
presence (Parker 1993). BPA will conduct the government-to-government tribal consultation for this project as per Section 106 of the NHPA.

To incorporate tribal involvement at an early stage in the process, the Applicant initiated contact with the Confederated Tribes and Bands of the Yakama Nation. The Applicant invited the participation of both the Yakama Nation Cultural Resources Department and two local resident tribal members to assist with the identification of potential sensitive, traditional, and/or sacred resources.

Through the Yakama Nation’s Cultural Resources Program (CRP), the Applicant requested participation of tribal members for the archaeological field inventory, sponsored a field trip to the Project Area, and solicited has attempted to solicit concerns with regard to potential cultural resources of importance to the tribe. The Applicant contacted the Yakama Nation Cultural Resources Department to review their confidential data sources and to report any potential areas of sensitivity, as appropriate, so that these areas can be avoided and protected early in the planning process. A field investigation by Yakama Nation cultural resources specialists occurred in December 2009. During this investigation, members of the Yakama Nation determined that there is a Traditional Cultural Property (TCP) within the Applicant’s APE. Due to the sensitive nature of the TCP, specific information regarding the type of TCP has not been included within this EIS. However, sacred sites such as these are important to the Yakama people of today and of the future. The Yakama Nation expressed opposition to construction of wind turbines within this area and recommended that the proposed Project be redesigned to avoid placing turbines on Chemawa Hill, or if full avoidance was not possible, then buffered zones should be established to protect the relevant features. In addition, the Yakama Nation also recommended avoidance of the Haran Farmstead. The Yakama Nation’s findings, currently in preparation, will supplement the information contained in this EIS.

Separate from Yakama Nation Cultural Resources Department, the Applicant invited the participation of two local residents, also members of the Yakama Nation, who have long-standing ties to the area. Chief Wilbur Slockish of the Klickitat Tribe and Chief Johnny Jackson of the Cascades Tribe met with URS archaeologists prior to the November 2009 field inventory and jointly toured the Project Area. Both individuals stated that based on their knowledge of this area, the Project Area was not specifically used by their ancestors or contemporary Indians. Neither individual identified any traditional cultural properties or other sensitive or sacred sites within the Project Area.

BPA initiated consultation with the DAHP, The Confederated Tribes of the Umatilla Indian Reservation, The Cowlitz Indian Tribe, The Confederated Tribes of the Warm Springs Reservation of Oregon, The Nez Perce Tribe of Idaho, The Confederated Tribes and Bands of the Yakama Reservation, and The Columbia River Inter-Tribal Fish Commission pursuant to 36 CRF 800.4(a)(4). On May 27, 2010, the Yakama Nation provided is cultural resources review and consultation report. On September 10th, 2010, BPA received a letter from the Yakama Nation stating that they did not agree with BPA’s interconnection APE and believed that it should include the Applicant’s APE as well. A BPA archaeologist spoke with a Yakama Nation archaeologist on March 31st, m 2011 regarding the APE. The Yakama Nation archaeologist noted that the Project application is undergoing an adjudicative review through EFSEC. On May
In 2011, BPA representatives and Yakama Nation representatives met to discuss the Tribes’ request for an expanded APE. It was discussed that BPA has no jurisdiction over siting of wind development facilities, a matter left to Washington EFSEC, and that BPA’s APE and Section 106 review was limited to the proposed interconnection.

The Yakama Nation participated in part of the adjudicative process as an intervener. The Yakima Nation formerly withdrew its adjudicative testimony before the adjudicative hearing began. The Applicant is committed to continue working with the Yakama Nation throughout the life of the Project. This includes adjusting the number of proposed towers to be located on Chemawa Hill.

The Yakama Nation and EFSEC went to adjudication due to issues regarding the cultural resources, including the TCP located within the Applicant’s APE. An agreement was reached between the Yakama Nation and EFSEC. In addition, in part in response to the Yakama Nation’s concerns, the Applicant reduced the number of towers located on Chemawa Hill. The Applicant also agreed to continue consultation with tribally-designated representatives as specific construction and siting occurs on Chemawa Hill and make adjustments where practicable to do so to address culturally sensitive areas.

Previously-Recorded Cultural Resources in the Project Vicinity

The DAHP maintains a state-wide database of previously-recorded cultural resource sites, historic register properties, and completed inventories. The locations of the cultural resource sites (e.g., archaeological sites) are managed as restricted access information. The locations of historic register properties (e.g., buildings and structures listed on the state or national register) are non-restricted information.

The DAHP database does not have any record of previous inventories within the Project Area including both the Applicant’s and BPA’s APEs. Prior inventory coverage in the general vicinity depicts a few small, scattered inventories in upland areas near Underwood Mountain, mostly related to development review projects in the Columbia River Gorge National Scenic Area. A limited linear inventory for a proposed timber sale occurred adjacent to and north of the Applicant’s APE and did not identify any resources (Stilson 2005). In general, few inventories have been completed in the vicinity; those that have been completed are limited in scope and do not allow for comparisons or predictions to be made about the types of resources that could be found in the Project Area. Intensive inventory coverage has only occurred along the White Salmon River drainage several miles to the east of the Project Area, where numerous pre-contact and historic period sites have been identified.

One cultural resource was previously-recorded within the Project Area, consisting of the Broughton Lumber Company flume (45GP596). The flume formerly paralleled Willard Road at the western boundary of the alternative location for the Maintenance and Operations facility. The flume was dismantled and removed from this area following the 1986 closure of the mill along the Columbia River. Although sections of the historic flume are still present elsewhere, none remain in the Project Area. This site therefore reflects a former alignment rather than extant physical remains.
Within a one-mile radius of the Project Area are two additional sites: a mortar and peeled cedar found about 0.5 mile west of the Maintenance Yard at Willard, and an early-twentieth century debris scatter associated with an old homesite, found about one mile north of the APE within a similar forested, upland setting. No historic register properties (e.g., buildings and structures) are found within the Project Area or within 1.5 miles of the Project Area based on the DAHP database.

In general, the density of cultural resources is greatest along the White Salmon River to the east, with scattered resources also found along the north shore of the Columbia River. Most archaeological research in the area has focused on riverine sites found along the Columbia River, and, more recently, along the lower White Salmon River. Fewer non-riverine archaeological sites have been documented in the general area, with several archaeological sites, mostly historic period, found in the Underwood Heights vicinity, several miles from the Project Area. It is unclear whether the higher site density documented along the White Salmon River is reflective of more intensive survey coverage, more intensive use of this area, or both, as compared to the Little White Salmon River. However, it appears unlikely that the higher elevation Project Area would have the same density of sites as the riverine areas along the Columbia and White Salmon rivers.

### 3.10.2.3 Project Area Inventory

A preliminary cultural resources inventory of the Project Area was conducted in 2003, based on the Project design at that time (Ballentyne 2003). Because the proposed Project Area was subsequently revised and expanded, a new survey was completed in 2009 (URS 2010). A wider survey corridor of 650 feet for the turbine strings necessarily overlapped the 2003 inventory’s 300-foot wide survey corridor. Much of the Project Area was therefore inventoried on two separate occasions, six years apart. The two survey areas are shown on Figure 3.10-2.

The 2009 URS inventory of the Project Area consisted of a pedestrian survey of the 384-acre APE where direct impacts to cultural resources could occur both within the Applicant’s APE and BPA’s APE. Prior to the field inventory, oral interviews were conducted with the landowner and local tribal informants, and historic maps and historic and modern aerial photos were reviewed to identify potential resources within the Project Area.

**Field Methods**

An intensive pedestrian survey of the APE was conducted for this Project in November 2009 for the cumulative 384-acre combined APE. Transects were spaced no greater than 100 feet (30 meters); most were at 65-foot (20-meter) intervals or less. Survey methods depended on the Project component being surveyed and the steepness of the slopes, as well as the presence of any hazards such as burning slash piles. Slopes greater than 30 percent were usually not inventoried. In several areas, survey coverage extended beyond the combined APE, depending on the topography. Ground visibility at the time of the inventory was variable; areas that had been most recently harvested provided excellent visibility, while forested areas were found to have dense accumulations of duff, slash, and dense vegetation that obscured the ground surface. Soil exposures provided by animal burrows, cut banks, roadways, and root casts were inspected closely.
Promontories associated with the proposed turbine strings were examined for potential rock cairns, rings, walls, or other alignments that could indicate sensitivity. Large old-growth stumps were examined for evidence of scarification, and large boulders were examined for evidence of petroglyphs, pictographs, or processing activities. The inventory was especially vigilant in looking for historic features such as residences, camps, roads, railroad alignments, flumes, or other evidence of historic logging and homesteading activities.

Limited subsurface probing was conducted for this Project at the location of an historic period archaeological resource, referred to as the Haran Farmstead, recorded at the time of the 2009 field inventory. This resource is located within one of the turbine strings, and is characterized by several rock features and a small artifact scatter related to an abandoned early-twentieth century residence and fruit orchard. The subsurface probing investigation employed close-interval systematic, as well as intuitive, sampling methods. Shovel probes were placed at close intervals around each of the recorded rock features to determine whether any associated archaeological deposits could be identified. Wider-spaced, systematic (20 to 30-meter interval) probes were placed within the lower-probability former orchard fields and within expansive areas found between several the rock features, where no surface artifacts were observed, to determine the presence or absence of buried resources.

A total of 52 shovel probes were excavated. The probes measured 30-cm in diameter and were generally excavated at 5 to 30-meter intervals to an average depth of 50 cm. Sediment was passed through alternating screen mesh sizes, both 1/4-inch and 1/8-inch mesh sizes were utilized. All artifacts were replaced within the excavated probe after documentation; none were collected.

Prior to subsurface probing, a metal detector was used to aid in the identification of metal artifacts obscured by the layer of duff that is present across much of the site due to its forested setting. The metal detector was used intensively around each of the recorded rock features. Systematic transects of 10 to 30 meters were walked in lower probability areas such as the former orchard field. Shovel scrapes, or simple removal of snow and duff to expose the ground surface soil, were utilized as an additional method to improve surface visibility. Shovel scrapes were placed at 30-meter intervals within the former orchard lands, where probability is considered low, in order to provide additional validity to the surface reconnaissance.

Beyond the Haran Farmstead, no additional exploratory probing was conducted elsewhere in the Project Area. The majority of the potentially higher sensitivity landforms such as the ridgelines and promontories either had excellent ground surface visibility due to recent timber harvesting activities, and/or had exposed basalt rock with little potential for subsurface soils. Much of the Project Area is characterized by steep topography where exploratory subsurface testing is neither warranted nor practicable. Although Little Buck Creek crosses the Project Area within a proposed Overhead Transmission Line corridor, this area was found to be a small stream crossing surrounded by steep terrain with no areas likely to contain potential cultural resources.
Inventory Results

The 2003 draft survey report, which was never finalized or submitted for agency review, preliminarily noted two separate resources, including an historic rock wall feature and a small, disturbed historic artifact scatter of glass, ceramics, and tin cans within a roadway (Ballentyne 2003). As part of the 2009 inventory, one historic period archaeological site, the Haran Farmstead, was identified within one of the turbine string corridors, and incorporates the rock wall feature identified in 2003. The historic artifact scatter previously documented in 2003 was not relocated during the 2009 inventory, and appeared to have been buried or obliterated by later road improvements in this same area (URS 2010).

The Haran Farmstead, documented in 2009, consists of several rock features and a sparse historic artifact scatter associated with a former rural homesite related to James A. Haran, who had a small plum orchard here around the 1920s. A total of nine archaeological features were recorded, including two rock walls24 (probable property or field clearing boundaries), two structural rock foundations (probable residence and milking parlor), and several rock features of indeterminate function but possibly remnants of appurtenances such as privy, pump house or food storage structures. One small concentration of fewer than 20 historic artifacts, including aqua and colorless glass fragments, galvanized metal water pipes, crockery and porcelain fragments, and tin cans, also was observed. Approximately 100 to 150 artifacts, mostly metal fragments and tin cans, were found scattered across the site during a pedestrian survey supplemented by use of a metal detector.

In December 2009, URS archaeologists conducted exploratory subsurface sampling across the site to define the site boundaries and to determine the presence or absence of associated buried deposits. About 20 artifacts were encountered during the subsurface probing investigation, limited to wire nails, a water pipe, several small colorless glass fragments, and metal can or non-diagnostic metal fragments.

The NRHP eligibility of the Haran Farmstead is addressed in the Cultural Resources Inventory Report. Each of the four criteria of eligibility is applied, and aspects of integrity are addressed. The Haran Farmstead is recommended as ineligible for the NRHP, due primarily to insufficient association and altered key aspects of integrity, which limit its potential to be considered under Criterion A (association with important events), Criterion B (association with important people), and Criterion C (having important characteristics of style). For Criterion D (information potential), the results of the inventory and exploratory subsurface probing indicate there is inadequate data potential to warrant eligibility. URS’s recommendation for ineligibility is pending agency review and concurrence.

Summary

One historic period cultural resource was identified within the combined APE: the Haran Farmstead archaeological site located with the Applicant’s APE, which consists of rock features

---

24 The Haran Farmstead as recorded in 2009 incorporates the rock wall observed during the 2003 inventory. The other resource identified during the 2003 inventory, a small concentration of historic artifacts found within an existing access road, was not located in 2009.
and a sparse artifact scatter related to a circa 1920s orchard and residence. Systematic subsurface probes were placed within this site and did not identify significant, buried deposits. The site was recommended as ineligible for the NRHP.

Additional historic farmsteads or other sites within the Project Area are not indicated by the results of archival research, which included review of historic maps and aerial photos. Field inventory confirmed that no aboveground resources, such as buildings, railroads, or flumes, are found in the Project Area.

A preliminary review of the ethnographic and ethnohistoric literature did not document this area as having any specific association for traditional resources, though uplands such as these could have been used at least transiently, for example, for plant resource gathering or spiritual purposes. The Applicant solicited participation of the Confederated Tribes and Bands of the Yakama Nation in order to identify any potentially sensitive resources or traditional cultural properties in the Project Area. Two local tribal members with long-standing ties to the area toured the Project Area and did not identify any cultural resources or concerns. The 2003 and 2009 inventories did not observe any pre-contact Native American site types, such as lithic scatters, petroglyphs, or peeled cedars during the inventory.

Only one water source was observed during the field inventory: the outlet of Little Buck Creek, downstream of the earthen dam that was constructed in 1947 to create the “Cedar Swamp” fire pond (located outside the APE). This small watercourse is surrounded by steep terrain and is not likely to have significant, associated archaeological resources.

Promontories associated with the proposed turbine string, especially Chemawa Hill and others with panoramic views of the surrounding area, were inspected closely for potential rock cairns, rings, walls, or other alignments that could indicate sensitivity. No such features were observed. It appears that even if such resources had been present, the historic and modern logging practices would have obscured this type of resource.

A cultural resource review was also conducted by the Yakama Nation’s Cultural Resources Program which identified culturally-sensitive areas, including Chemawa Hill. Chemawa Hill is located within the Applicant’s APE, and the Applicant is currently proposing to place turbines at this location. Due to the sensitive nature of the site, specific information regarding the TCP will not be included in this EIS, but the area has been identified by the Yakama Nation as sacred. The Applicant has agreed to reduce the number of turbines located on Chemawa Hill and would continue to collaborate with the Yakama Nation on siting modifications where practicable.

Although the Project Area was logged at least 100 years ago, no features such as camps, historic roads, railroad features, or other evidence clearly related to the historic use of the area was observed. Large old-growth stumps are occasionally encountered, but most are in an advanced state of decay and springboard notches were not observed. No evidence for historic road alignments was observed during the inventory; existing roadways are mechanically-graded, usually rocked and graveled, modern-use alignments that lack historic distinction. As no old-growth forest remains in this area, potential sensitivity for scarified, peeled trees is not indicated.
Much of the current combined APE examined in the Cultural Resources Inventory Report conducted in 2009 was surveyed in 2003. This overlapping of inventory coverage, nearly six years apart, at different times of the year, and with the surrounding forest in different stages of harvest, provides additional support for a general absence of cultural resources to be found in the APE.

3.10.3 IMPACTS

3.10.3.1 Proposed Action

Construction

The proposed Project has the potential to affect one historic period archaeological site, the Haran Farmstead, through ground disturbance during construction of the new Project road and turbine and transformer pads. The degree of impact would depend on the final location of the road and turbines. The Cultural Resources Inventory Report, however, recommended this site as ineligible for the NRHP; and there were no archaeological resources identified within the BPA APE.

Construction also would have the potential to impact other, currently undiscovered cultural or historic resources. Based on the extensive inventories conducted, the likelihood of encountering additional sites is low.

There have been no cultural resources identified within the BPA APE. Within the Applicant’s APE, one TCP was identified by the Yakama Nation in relation to Chemawa Hill. The Applicant has agreed to continue to work with the Yakama Nation throughout the proposed Project and will also site fewer turbines on top of Chemawa Hill.

Effects on traditional cultural properties or other sensitive or sacred resources that might be of concern cannot be determined until consultation with the tribes is concluded. This consultation is not expected to be completed until after the Draft EIS is issued.

Operation

The ongoing maintenance of the access road or emergency procedures such as fire suppression activities have the potential to cause additional impact to the Haran Farmstead or other, currently undiscovered resources.

Project Decommissioning

Project decommissioning could have impacts similar to those during initial construction, including ground disturbance from turbine, transformer and pad removal. As with construction, the degree of impact would depend on the final location of the road and turbines, and on the determination of NRHP eligibility for the Haran Farmstead.
3.10.3.2 No Action Alternative

Under the No Action Alternative, the Project would not be built and no impacts to historic or cultural resources would take place.

3.10.4 MITIGATION MEASURES

The following mitigation measures are identified to avoid, minimize, and compensate for potential cultural resource impacts during construction and operation of the proposed Project to the extent feasible.

- Implement avoidance and data recovery if the Haran Farmstead (a historic period cultural resource recorded within the APE) is determined to be eligible for nomination to the NRHP. The Haran Farmstead archaeological site, which consists of rock features and a sparse artifact scatter related to a circa 1920s orchard and residence. If the Haran Farmstead is determined to be eligible for nomination to the NRHP, then avoidance and mitigation measures such as data recovery would be considered to achieve a finding of no adverse effect for the project. Though none have been identified to date within the project area, properties considered as significant for reasons other than research potential, such as traditional cultural properties, may require mitigation measures other than data recovery that would be determined in consultation with the Tribe and agencies.

- Utilize BMPs to minimize impacts to any additional cultural or historic resources that may be encountered during construction of the proposed Project. These BMPs include preparation and use of an Inadvertent Discovery Plan, which would establish procedures to deal with unanticipated discovery of cultural resources before and during construction. The plan, among other provisions, would require immediate work stoppage and appropriate notification in the event of discovery of previously unknown cultural materials. The plan also would specify protocols for the treatment of human remains that fulfill the requirements of the Native American Graves Protection and Repatriation Act in the event that human remains and/or funerary items are encountered during construction or operation of the Project.

- Design the locations of road, turbine, and transformer to avoid and minimize impacts during construction regular maintenance operations. Although Chemawa Hill was identified as a TCP within the Applicant’s APE, the Applicant has worked with the Yakama Nation to site fewer towers on Chemawa Hill and are committed to working with the Yakama Nation during the proposed Project.

3.10.5 UNAVOIDABLE ADVERSE IMPACTS

With the use of appropriate mitigation measures, the proposed Project is not expected to produce any unavoidable impacts to historic or cultural resources.

3.11 TRANSPORTATION

This section discusses the existing network of roadways and rail, river, and air transportation in the Project vicinity, as well as the potential impact of the proposed Project on transportation.

3.11.1 AFFECTED ENVIRONMENT

3.11.1.1 Roadway Transportation

Existing Roadways

In the Columbia River Gorge, the two major roadways extending generally from east to west along the Columbia River are State Route (SR) 14 on the Washington side of the Columbia River and Interstate 84 on the Oregon side of the Columbia River. Other major roadways, such as State Routes 141 and 142 in Washington and State Routes 35 and 197 in Oregon, intersect these two highways generally in the vicinity of cities and communities located in the Gorge.

SR 14 between Interstate 5 in the Vancouver, Washington area and the Project Area is generally very narrow with 12-foot lanes and 2- to 4-foot paved shoulders. It also has many hills, and curves with tight corners in several places. East of the Project Area on SR 14, there is one low and very narrow tunnel east of the town of Lyle, Washington, and also a very narrow bridge east of The Dalles at approximately milepost (MP) 86. Between Cook-Underwood Road and SR 97 (Goldendale), SR 14 is generally narrow with 12-foot lanes and 2- to 4-foot paved shoulders. It also has some tight low-recommended-speed corners and a number of hills. Between SR 97 and the junction with SR 395/I-82, SR 14 is generally narrow with 12-foot lanes and 2- to 4-foot paved shoulders.

Existing access to the Project Area is provided by various county roads that extend northward from SR 14, along with existing private logging roads (see Figures 3.11-1 and 3.11-2). Key roads in the immediate Project vicinity include:

- **Cook-Underwood Road.** Cook-Underwood Road has two 12-foot lanes and paved shoulders that are 1 foot or less in width. In general, the side slope begins at the fog line. This road is under the jurisdiction of Skamania County and generally is in good condition. There are currently no over-size or over-weight load restrictions in force. The Skamania County Comprehensive Plan lists Cook-Underwood Road as Federal Functional Classification “Major Rural Collector.”
• **Willard Road.** Willard Road has two 12-foot lanes and paved shoulders that are 1 foot or less in width. This road is under the jurisdiction of Skamania County and generally is in good condition. There are currently no over-size or over-weight load restrictions in force. The Skamania County Comprehensive Plan lists Willard Road as Federal Functional Classification “Rural Local Access.”

• **West Pit Road.** West Pit Road is a private logging road that connects to a network of existing private logging roads located on S.D.S. Co., LLC and Broughton Lumber Company property. West Pit Road varies in width from 20 to 26 feet. It is a dirt road covered in light pit run. This road has portions that generally are in poor condition; however, during summer 2009, various roadway improvements were made and segments of the road were widened for logging purposes.

**Existing Traffic Volumes**

Average annual daily traffic (AADT) values for SR 14 are shown in Table 3.11-1. Peak hour directional volumes were developed based on typical rural highway traffic patterns and proximity of business centers. Typical rural highway traffic patterns conservatively assume AM peak hour volumes to be approximately 7 percent of the total daily volumes, and PM peak hour volumes to be approximately 10 percent of the total daily volumes, with a directional split of 70/30. PM peak hour volumes are traditionally considered to be the highest during a given day. Since no current traffic data is available for Cook-Underwood Road at either the west or east junctions with SR 14, existing traffic volumes are based on typical patterns for small rural towns. Estimated 2009, 2011, and 2012 peak hour traffic volumes at the west and the east junctions of Cook-Underwood Road with SR 14 are presented in Table 3.11-2. Traffic volumes for 2011 and 2012 were based on an expected average weighted growth rate of approximately one percent per year.

Source: WSDOT (2008)

* A growth rate was developed for the Project vicinity using historic data from annual traffic reports between 1996 and 2008. During several years between 1996 and 2008, there was no recorded historical growth in this area. Using this data, an average weighted growth rate of approximately 1 percent per year was determined.

**Existing Level of Service**

Level of service (LOS) is an estimate of operational performance based on delay to motor vehicles. The *Highway Capacity Manual* (TRB 2000), which is generally used when determining LOS, defines LOS using a letter scale from A to F. LOS A is defined as minimal or no delay to vehicles and LOS F is defined as extreme delays to vehicles. LOS C or better is typically considered acceptable for rural intersections and is the LOS threshold of acceptable traffic flow for Skamania County. Table 3.11-3 presents the LOS delay criteria for two-way-stop-control intersections.

Source: TRB (2000)

Existing LOS was estimated for SR 14 and Cook-Underwood Road, using estimated 2009 traffic volumes and the software package Highway Capacity Software Plus, which uses algorithms based on the *Highway Capacity Manual* (TRB 2000). Based on this analysis, the longest delays occur at Cook-Underwood Road during the PM peak hour; however, these delays are relatively short (see Table 3.11-4). Up to approximately 10 seconds of delay is experienced by some vehicles at the west junction of Cook-Underwood Road with SR 14 during the PM peak hour. Slightly more than 10 seconds of delay is experienced by some vehicles at the east junction of Cook-Underwood Road with SR 14 during the PM peak hour. These delays translate to LOS A conditions at the west junction and LOS B at the east junction. Delays during the AM peak hour at Cook-Underwood Road and during both peak hours at SR 14 are all less than 10 seconds, which translates to LOS A.

Existing Traffic Safety

Traffic safety was analyzed along SR 14 between the towns of Stevenson and Bingen for 2006 to 2008. Collision Data Summaries were obtained from WSDOT. SR 14 is functionally classified as a rural collector roadway. SR 14 between Stevenson and Bingen is located within the Southwest Region of the state of Washington. During this three-year period, a total of 158 collisions occurred between the west city limits of Stevenson at MP 43.91, and the east city limits of Bingen at MP 66.88.
Between 2006 and 2008, a total of 17 collisions occurred within the Stevenson city limits, and another 17 occurred within the Bingen city limits. Only one collision occurred at the west junction of Cook-Underwood Road and SR 14 (MP 56.28), and three collisions occurred at the east junction of Cook-Underwood Road and SR 14 (MP 63.32). Four collisions occurred at the intersection of Maple Street and SR 14 within the city of Bingen (MP 66.47). The majority of collisions occurred within Skamania County between MP 44.66 and MP 63.48. Several collisions also occurred within Klickitat County between MP 63.48 and MP 64.71, and within the White Salmon city limits between MP 64.71 and MP 65.50.

The number of collisions that occur along a given roadway is generally expressed in terms of a rate, where collision occurrence is indexed to the number of vehicles traveling on a particular length of the given roadway. The collision rate is based on the number of collisions per million-vehicle-miles (MVM) traveled. Table 3.11-5 shows collision rates for each year as well as multi-year rates for the three year period for SR 14 between Stevenson and Bingen, in addition to collision rates for the city of Bingen.

The multi-year collision rate along SR 14 between Stevenson and Bingen is 1.43 collisions per MVM. The 2007 average collision rate for all Washington state rural collector roadways was 1.65 collisions per MVM and for 2008, 1.63 collisions per MVM. The average collision rate for all Washington rural collector roadways within the Southwest Region during 2007 was 1.72 collisions per MVM, and during 2008, 1.87 collisions per MVM. The multi-year collision rate on SR 14 between Stevenson and Bingen is lower than both the 2007 and 2008 average Washington State and Southwest Region collision rates.

</table>

AADT – average annual daily traffic
MVM million-vehicle-miles
The multi-year collision rate for the city of Bingen is 1.63 collisions per MVM. The multi-year collision rate for the city of Bingen is equal to or close to both the 2007 and 2008 Washington State collision rates and is lower than both the 2007 and 2008 average Southwest Region collision rates. No average collision rate data is available for year 2006.

**Transportation Plans and Programmed Transportation Improvements**

**Skamania County.** The Transportation Element of the Comprehensive Plan represents the County’s policy plan for the next 20 years and specifically considers the location and condition of the existing traffic circulation system, the projected transportation needs, and plans to address future transportation needs while maintaining established LOS standards. This plan is implemented through the Six-Year Transportation Improvement Program and Annual Construction Program. The most recent Six Year Transportation Improvement Program was approved in April 2009, and lists one improvement to Cook-Underwood Road: a resurfacing project between MP 0 and MP 3. This improvement is listed for years 4–6 of the program, or between 2012 and 2014.

**Washington State Department of Transportation Statewide Transportation Improvement Program.** This is a list of funded transportation improvement projects. The Transportation Improvement Program for 2009–2012 presents a list of regionally significant projects for the upcoming three years (WSDOT 2009a). A search of the project database for Clark, Skamania and Klickitat Counties showed no projects scheduled for any of the roads in the immediate Project vicinity. The only planned transportation improvement project near the Project Area is resurfacing 1.0 mile of Wind River Road.

WSDOT also is planning to improve SR 14 between Camas and Washougal, east of Vancouver. The project would widen SR 14 from two lanes to four lanes from the end of the West Camas Slough Bridge to Union Street (SR 500). Included in the project would be construction of a new bridge parallel to the existing bridge on the east end of Lady Island, and construction of a split-diamond interchange at Union Street and 2nd Street. The project is planned to go to bid in 2010, and construction is scheduled to be completed in 2012 (WSDOT 2009b).

**Skamania County and Klickitat County Regional Transportation Plans.** These Regional Transportation Plans were developed by the Southwest Washington Regional Transportation Council, in coordination with other jurisdictions and WSDOT (SWRTC 2009a and 2009b). Regional transportation plans are intended to develop regional solutions to transportation needs. Both plans emphasize maintenance and preservation as priorities. Improvements are recommended to address identified deficiencies. Recommended improvements in these plans include several projects to upgrade portions of SR 14. However, funding is not provided through this planning process and these projects are not currently included in the Statewide Transportation Improvement Program.

### 3.11.1.2 Rail Transportation

The Burlington Northern Santa Fe Railway operates a rail mainline that runs parallel to SR 14 to the south of the Project Area. This line is a major link that ties the important industrial areas of Vancouver, BC; Portland, Oregon; and Seattle/Tacoma, Washington to the north-central states of
the United States and eastern railroads via Chicago. In the Project vicinity, the Applicant currently has two rail spurs from the Burlington Northern Santa Fe mainline to an existing Applicant facility located along the Columbia River in Bingen, Washington. One spur terminates near Maple Street and is approximately 800 feet long. The second spur terminates at a plywood facility in the area and is approximately 2,000 feet long.

3.11.1.3 River Transportation

River transportation in the Project vicinity includes barge and boat shipping transport on the Columbia River, which is located about two miles south of the Project Area and runs predominantly east to west towards the Pacific Ocean. The Columbia River is a major throughway used for transporting commodities such as grain, wheat, and lumber down river from the interior Pacific Northwest to ports such as the Ports of Longview and Vancouver for shipping to various U.S. and international destinations. The Columbia River also is used to ship goods upriver to destinations in the interior Pacific Northwest. Although there are many hydroelectric dams and associated lockage facilities along the Columbia River, the only such facility between the Pacific Ocean and the Project Area is Bonneville Dam, at about river mile 146 on the Columbia River.

Barges moving upriver from the Ports of Longview or Vancouver are transported to the Bonneville Dam using tug boats. The barges and tugs bypass the Bonneville Dam via the lockage facility at the Dam. The Bonneville lockage facility accommodates commercial, government, and recreational vessels. The heaviest lockage traffic on average occurs during the month of August. Vessel traffic is typically heaviest on Thursdays, Fridays, Saturdays, and Sundays. River vessels then continue upriver past the applicant facility in Bingen. At this Applicant facility, there is a dock and crane suitable for unloading heavy materials and other equipment.

3.11.1.4 Air Transportation

Air transportation in the regional area includes the Portland International Airport approximately 60 miles southwest of the proposed Project Area, and several other smaller public and private local airports within a 10-mile radius.

3.11.2 IMPACTS

To determine potential transportation impacts, the Skamania County Public Works Department Manager, the County Engineer, and the Maintenance Superintendent were consulted. Potential impacts to potential Project access routes were considered, and levels of service were estimated for the construction and operation periods. Impacts were considered high if they would result in a decrease in LOS to below the Skamania County standard of LOS C at a given intersection after mitigation. Impacts would be moderate if the Project would result in a modest change to traffic volumes, patterns, or LOS. Impacts would be low if the Project would result in no noticeable change to traffic volumes, patterns, or LOS. Potential impacts to rail, river, and air transportation also were evaluated to determine whether there would be significant increases in uses or interference with their operations.
3.11.2.1 Proposed Action

Construction

Impacts to Project Vicinity Roadways

During Project construction, various types of construction vehicles would access the Project Area. Most Project construction vehicles would be expected to travel to the general Project vicinity via SR 14 since it is the most convenient major highway leading to the area. From SR 14, the construction access route would follow Cook-Underwood Road to Willard Road, and then use a short segment of newly-constructed roadway to access West Pit Road (see Figure 3.11-2). From West Pit Road, construction vehicles would use a network of existing, improved, and new private logging roads at the site to access areas where Project facilities would be built (see Figure 3.11-3).

Project construction would last for approximately one year, and would involve transport of large wind energy components, such as the tower sections, the nacelle and turbines, and blades, to the Project Area during a two to three month period. All wind energy components initially would be delivered from their manufacturing points to one of two ports in Washington state – either the Port of Longview or the Port of Vancouver. From these Ports, the Project components would be transported to the Project Area. Potential methods for transporting these materials to the Project Area include:

- Using specialized trucks that would use existing State, County, City, and private roadways to deliver the components directly to the Project Area;

- By train via the existing Burlington Northern Santa Fe rail lines that run parallel to SR 14 to deliver the components to an existing Applicant facility in Bingen, Washington, and then using specialized trucks to deliver these components to the Project Area; and

- By barge and tug boat up the Columbia River and through the lockage facility at the Bonneville Dam to the Applicant’s existing facility in Bingen and then via specialized trucks to the Project Area.

Potential impacts associated with specialized trucks are discussed in this subsection of the analysis; the rail and river transport options are discussed later in this section. The specialized trucks used for transporting wind energy components could have loads as high as 17.5 feet tall measured from the ground to the highest point of the load, as wide as 14.5 feet, and/or as long as 150 feet. While most of these trucks would not exceed the WSDOT legal load limit, some trucks could have a gross vehicle weight in excess of 105,500 pounds. Trucks with loads in excess of the legal load limit could degrade the condition of the existing roadways along the proposed haul route, and may require additional axles in order to distribute the weight of the load. Permits would be required for all oversized and overweight vehicles.

Most specialized trucks delivering components directly from either of the Ports to the Project Area would be expected to use SR 14 to the west junction of Cook-Underwood Road with SR 14 at MP 56.28 (see Figure 3.11-2). These trucks would encounter restrictions on SR 14 that are summarized in Table 3.11-6, and could require additional traffic control measures. However, SR
14 would not require improvements to accommodate the trucks the transport of wind energy components.

Due to the road constraints discussed in Section 3.11.1.1 and identified in Table 3.11-6, the use of specialized trucks on SR 14 may not be physically possible for some extremely large or wide loads. An alternate route would be for trucks to use I-84 through Oregon to the Boardman junction, then along SR 730 to the junction of I-82 with SR 395, across the Columbia River back into Washington State and then to SR 14. Trucks traveling on SR 14 in this direction, between the junction of I-82/SR 395 and Cook-Underwood Road, would be constrained by one very narrow tunnel with a height restriction of 13 feet 3 inches measured vertically from the edge of the roadway. There also are several additional Columbia River crossings west of the I-82/SR 395 crossing, but each has weight restrictions that would prohibit the transport of wind energy components. These crossings include the Bridge of the Gods, the Hood River Bridge, SR 197, and SR 97.

Table 3.11-6

</tr>
</tbody>
</table>

* Heights are measured from the ground to the highest point on the load.

For wind energy components transported either by rail or barge as discussed below, these components would be delivered from either of the Ports to the existing Applicant facility in Bingen, Washington, and then loaded onto specialized trucks at this facility. The trucks would then transport the components to the Project Area. The route for these trucks would include approximately 0.25 mile of Maple Street in Bingen, Washington. Maple Street was recently constructed and is in good condition. Maple Street has two 12-foot lanes, a wide concrete sidewalk on the east side, and a paved shoulder on the west side. There are currently no oversize or overweight restrictions for this road.
Figure 3.11-3

Project Site Roadway Network

Whistling Ridge Energy Project
Skamania County, Washington

Source: GeoDataScape.
Specialized trucks leaving the Applicant’s facility would then follow SR 14 to the east junction of SR 14 and Cook-Underwood Road at MP 63.32. This portion of SR 14 has a restriction on loads over 125 feet in length. Special provisions and/or permitting may be required to transport the turbine blades (the longest components) to the junction of SR 14 and Cook-Underwood Road at MP 63.32 from the junction of SR 197 (MP 83.50).

Improvements to County and private roads between SR 14 and the Project Area would be necessary to support the long and heavy loads that would be required for the delivery of the wind energy components. These improvements would include widening and rebuilding sections of the existing roadway network, as well as placing asphalt on some roads that would be used for hauling equipment and Project components to the Project Area. All existing county roadways requiring improvements prior to hauling would be designed and constructed in accordance with the WSDOT Design Manual (WSDOT 2007) and A Policy on Geometric Design of Highways and Streets (AASHTO 2004).

Cook-Underwood Road contains a bridge that crosses the Little White Salmon River near its northernmost point at approximate MP 5.5. Specialized trucks would be required to meet Skamania County provisions for oversized and overweight loads. Cook-Underwood Road would require no improvements to accommodate the transport of wind energy components. However, specialized trucks transporting wind energy blades, the longest single wind energy component, eastbound on SR 14 onto Cook-Underwood Road at MP 56.28 or westbound onto Cook-Underwood Road at MP 63.32 would require a 135-foot inside turning radius, and a 20-foot allowance for “tip swing.”

In addition, temporary widening of the intersection of Cook-Underwood Road and Willard Road would be required to accommodate the required truck turning radii for westbound trucks transporting wind energy blades to the Project Area. Widening could include removal of some trees and vegetation, and engineered fill sections and embankment cut sections. The engineered fill and embankment cut sections would not require paving, but would require an all-weather driving surface. The exact amount of right of way or easement that might be required from adjacent property owners would depend on the turbines chosen, and would be determined during final design. Following construction, the area would be re-vegetated. No other improvements would be required along Willard Road to accommodate the transport of wind energy components.

A new direct connection across property owned by the Applicant would be required between Willard Road and West Pit Road for transport of larger Project components to the Project Area. The intersection of Willard Road and West Pit Road would be designed to accommodate the required truck turning radii. In addition, West Pit Road would require additional permanent widening to accommodate transport of wind energy components to the Project Area. West Pit Road would be improved to provide a minimum drivable section width of 25 feet (width of finished road), with an additional 5 feet of shoulder on either side, with allowance for side slope and drainage. The one existing culvert, which was upgraded during the summer of 2009, may need some additional lengthening if the roadway is widened over the culvert. Widening could include removal of trees and vegetation, and engineered fill sections and embankment cut sections. The engineered fill and embankment cut sections would not require paving, but would require an all-weather driving surface.
Roadway Construction in the Project Area

To provide access to all of the proposed wind tower locations, approximately 7.9 miles of existing roads would be improved and about 2.4 miles of new private access roads would be constructed at the Project Area (see Figure 3.11-3). All roadway improvements and new construction at the proposed Project Area would be designed and constructed in accordance with the standards for the applicable road classifications as set forth in the Skamania County Private Road Guidelines and Development Assistance Manual, as adopted by the County Resolution in 2008.

New gravel roadways would extend toward and run along the turbine strings. Roads extending towards the turbine strings would be designed for a minimum drivable section width of 25 feet with allowance for side slope and drainage. Roads running along or between the turbine strings would be designed for a minimum drivable section width of 25 feet with an additional 5-foot section on both sides to accommodate drainage and clearance for the Project crane that would be on site to assemble the tower sections, the nacelles, and blades. All newly constructed roads would be constructed with an all-weather driving surface.

During construction, parking would be located at the construction staging area and along the proposed Project Area access roads. Parking along turbine string roads would be primarily for those employees working on foundations, electrical infrastructure, and turbines. Vehicles would park in areas that would be already temporarily or permanently disturbed from other construction activities. No additional ground disturbance would occur solely for construction parking requirements.

Impacts to Traffic Volumes and LOS

During Project construction, there would be an increase in traffic activity in and around the Project Area due to the construction workforce, equipment deliveries, and empty trucks returning to SR 14. Traffic delays could occur on Project Area roads due to the maneuvering of large vehicles carrying heavy and/or long loads. In addition, it is expected that approximately 265 personnel would be on site at the same time while multiple construction disciplines conduct work concurrently. Between 65 and 75 percent of the construction labor force would most likely be hired from the cities of Portland and Vancouver; of these, most are expected to commute daily to and from the Project Area. The remaining 25 to 35 percent of the work force would most likely be residents of Skamania, Klickitat, and Hood River counties.

Traffic volumes during construction were estimated for the west and east junctions of Cook-Underwood Road with SR 14. The estimated traffic volumes assume that all construction vehicles related to Project construction would travel through either the east or the west junction Cook-Underwood Road with SR 14; if other routes were used, the actual impacts to these junctions would be less.

Table 3.11-7 compares estimated traffic volumes without the proposed Project to estimated traffic volumes with the proposed Project during the peak construction period. As shown in this table, it is expected that at the peak of construction (a period of three to five months) during the AM peak hour, approximately 210 construction vehicles would travel through either junction of SR 14 and Cook-Underwood Road. During the PM peak hour, approximately 10 construction
vehicles would be expected to travel through this same junction. Also during this construction peak, an increase of up to 275 vehicles total would be southbound on Cook-Underwood Road from the Project Area during the PM peak hour.

AM Peak Hour is 7:00 AM to 8:00 AM  
PM Peak Hour if 4:00 PM to 5:00 PM

Peak-hour LOS analyses were completed for both the west and east junctions of SR 14 and Cook-Underwood Road using estimated 2011 traffic volumes, including non-project traffic and traffic related to construction. The analysis assumed that 65 to 75 percent of construction traffic trips would travel to and from west of the Project Area on SR 14, and 25 to 35 percent of construction traffic trips would travel to and from east of the Project Area on SR 14. Many of these trips would occur outside of the peak periods, depending on their origin location and start time. Analyses results are presented in Table 3.11-8.

Delay = Average per vehicle
Based on this analysis, estimated 2011 traffic volumes, including construction vehicles, would have minimal impact on the LOS at either junction of SR 14, which would maintain LOS A. For vehicles turning left or right from Cook-Underwood Road at either the west or the east junctions of Cook-Underwood Road with SR 14, delays would increase up to approximately six seconds per vehicle over estimated 2011 conditions. The southbound approach on Cook-Underwood Road at the west junction with SR 14 would experience degradation in LOS from A to B during the AM hour over estimated 2011 operations. The southbound approach on Cook-Underwood Road at the east junction with SR 14 would experience degradation in LOS from A to B during the AM peak hour over estimated 2011 operations. LOS B operations would be maintained at both the west and east junctions of Cook-Underwood Road with SR 14 during the PM peak hour with no change in LOS over year 2011.

Traffic Hazards

Traffic hazards associated with construction projects generally relate to accidents. Construction of the Project would require that many construction vehicles, including trucks with oversized and overweight loads, share the existing roadway network with the general public. As a result, some accidents could occur that would be directly attributable to construction traffic. This increase is expected to be temporary and minimal. Prior to Project construction, coordination would be required between the owner, contractor, the Cities of Bingen and White Salmon, Skamania County, and WSDOT to ensure the highest level of safety possible for both the traveling public and the construction vehicles. This coordination would be particularly important during the summer months when the cities of Bingen and White Salmon experience an increase in traffic volume from recreational activities in the surrounding area.

SR 14 in the vicinity of the proposed Project Area is a two-lane undivided rural highway with limited access. Access points in the proposed Project vicinity do not include roadway channelization for turning movements. PM peak traffic volumes at both the east and west intersections of SR 14 with Cook-Underwood Road would increase from an estimated 10 vehicles without the Project to an estimated 285 vehicles with the Project (see Table 3.11-7). While traffic delay would increase by approximately four seconds (see Table 3.11-8), LOS at both intersections in the PM peak would remain at LOS B. Construction worker traffic (workers travelling to and from the job site) is anticipated to have minor effects on traffic safety. Potential moderate impacts to travel safety could occur due to the turning movements of oversized and overweight trucks onto and off of Cook-Underwood Road during the peak construction period.

Impacts to Railroad Transportation

Some wind energy components also may be transported from either the Port of Longview or Port of Vancouver by rail to the existing Applicant facility in Bingen, Washington. Wind energy components on rail cars can be up to 14.5 feet in width, up to approximately 15 feet in height, and as long as 150 feet. The wind energy components likely would be transported on standard or heavy-duty 89-foot long flat rail cars. These components would be off-loaded at the Applicant’s facility to a staging location to be determined and loaded onto specialized trucks for transport to the Project Area.

Although the Burlington Northern Santa Fe rail line between Vancouver, Washington and the Applicant’s facility could accommodate most wind energy components, this rail line may not be
able to accommodate loads with widths in excess of 14 feet. This may preclude transport by rail of the wide bottom sections of the wind turbine towers; however, the nacelles, turbines, blades, and upper sections of the wind turbine towers still could be transported by rail. Because rail transport would only be used for components that could safely be transported by rail and would be accomplished within existing railroad schedules, impacts to rail transportation are expected to be minimal to low.

**Impacts to River Transportation**

Potential impacts to river transportation would occur only if wind energy components were transported by barge from either the Port of Longview or Port of Vancouver to the Applicant’s facility in Bingen, Washington. The wind energy components would be transported from the Ports upriver to the Bonneville Dam using by barges and tugboats. The barges and tugboats would bypass the Bonneville Dam via the lockage facility, and continue upriver to the existing Applicant’s facility in Bingen, Washington. The wind energy components would be off-loaded at the Applicant’s facility to a staging location to be determined and loaded onto specialized trucks for transport to the proposed Project Area.

There would be no oversized or overweight restrictions using barges at either of the Ports, on the Columbia River, or at the lockage facility at the Bonneville Dam. Coordination with the Bonneville Dam Project Office would be required to determine optimal times for lockage use. Because there would be no interference with river operations and shipping of Project materials would be accomplished within existing lockage schedules, construction impacts to river transportation are expected to be minimal to low.

**Impacts to Air Transportation**

Temporary construction equipment such as cranes and derricks that would be used for the construction of the proposed towers could pose a hazard to aviation safety during the construction period, depending on their height. A “Determination of No Hazard to Air Navigation” likely would need to be obtained for certain taller wind energy components, such as the wind turbines, that would be constructed at the Project Area. It is not expected that local or regional airports would be used for transporting construction equipment or material, and no air transportation impacts would be anticipated.

**Operation**

Project operation would generate small volumes of additional traffic associated with workers commuting to the Project and occasional service delivery trips. Project operation workers would generate approximately 30 daily trips, with service delivery trips ranging from zero to usually no more than four daily trips. Although the Project would operate 24 hours a day, seven days a week, using an automated system, the operations crew would typically work eight-hour days Monday through Friday. The distribution of operational traffic trips is expected to be the same as for construction trips.

**Impacts to Project Vicinity Roadways**

Vehicles trips generated during Project operation would consist primarily of employees commuting to and from the site in their personal vehicles. The number of additional trips, and
the types of vehicles used, are not expected to exceed State or County roadway legal load limits. These vehicles would not contribute to roadway degradation.

**Impacts to Traffic Volumes and LOS**

Peak-hour traffic volumes were estimated for operations at both the west and east junctions of SR 14 and Cook-Underwood Road. These estimates include 2012 baseline traffic volumes and the project-generated traffic volumes. Like the analysis of traffic volumes during construction, the estimated traffic volumes assume that all vehicles during Project operation would travel through either the east or the west junction Cook-Underwood Road with SR 14; if other routes were used, the actual impacts to these junctions would be less. Table 3.11-9 compares estimated traffic volumes without the proposed Project to estimated traffic volumes with the proposed Project during full operation of the Project.

AM Peak Hour is 7:00 AM to 8:00 AM
PM Peak Hour is 4:00 PM to 5:00 PM

Peak-hour LOS analyses were completed for both the west and east junctions of SR 14 and Cook-Underwood Road, based on the estimated 2012 traffic volumes. The results indicate that operations would have a minimal impact on the LOS for either the west or the east junctions of Cook-Underwood Road with SR 14. Delays would increase slightly—less than one second per vehicle—for vehicles turning left or right from Cook-Underwood Road at either the west or the east junctions of Cook-Underwood Road with SR 14 over estimated 2012 operations. LOS A and B operations would be maintained during the AM and PM peak hours at both the west and east junctions of Cook-Underwood Road with SR 14 with no change in LOS over year 2012. Analyses results are presented in Table 3.11-10.

Delay = Average per vehicle

During operations, employees would park at the Operations and Maintenance facility parking lot. There would be approximately 10 vehicles each day, including employee and delivery vehicles. A maximum of approximately 20 vehicles are expected to be parked in the Operations and Maintenance facility parking lot at any one time. A visitor kiosk is also planned at the Operations and Maintenance facility that would provide tourists with a safe place to view and learn about wind turbines. The parking lot would be sized to accommodate these uses.

Traffic Hazards

Because of the low volumes and infrequent trips, Project operation is not expected to increase traffic hazards or accident occurrences.

Impacts to Railroad and River Transportation

Once construction is complete and the Project is operational, it is expected that there would not be any use of railroad or river transportation for the proposed Project. Because there thus would be no interference with railroad or river operations, there would be no expected impacts to railroad and river transportation during Project operation.

Impacts to Air Transportation

The proposed wind turbines would not be expected to conflict with arriving or departing aircraft from either the public or private airports within the Project vicinity. All towers would meet Federal Aviation Administration regulations regarding lighting. A “Determination of No Hazard to Air Navigation” would be obtained for the proposed Project. The Federal Aviation Administration would need to be notified of any alterations to the wind turbine towers that could affect air space.

**Project Decommissioning**

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is suspended or terminated during construction or before it has completed its useful operating life. The plan would include or parallel a decommissioning plan for the Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major transportation issues presently anticipated, including impacts to traffic volumes and LOS standards. If impacts to transportation are anticipated to occur as a result of site restoration and Project decommissioning, mitigation measures would be proposed as part of the plan.

3.11.2.2 **No Action Alternative**

Under the No Action Alternative, the Project would not be constructed and therefore no additional auto or truck trips would be added due to the Project. No impacts upon any type of transportation (road, rail, air, or river) would occur.

3.11.3 **MITIGATION MEASURES**

The following mitigation measures are identified to avoid, reduce, or compensate for potential Project impacts to transportation.

- Prepare and implement a Transportation Management Plan to direct and obligate the contractor to implement procedures to minimize traffic impacts in consultation with both WSDOT and Skamania County. The plan should be submitted to EFSEC for approval and include requirements for coordination of project-related construction traffic and WSDOT planned construction projects, along with requirements for coordination of project-related construction traffic and Skamania County, City of Bingen, and City of White Salmon summer recreational traffic.

- Comply with State and County permitting requirements for over-size and over-weight vehicles.

- Notify land owners in the Project vicinity prior to construction of transportation routes that would be used for construction equipment and labor.

- Place approved State and/or County advanced warning construction signs prior to and during construction.

- Use certified flaggers when necessary to direct traffic when over-size and over-weight trucks either enter or exit public roads, to minimize risk of accidents.

- Avoid restricting traffic flow for more than 20 minutes during the construction phase.
• Use pilot cars both in front of and behind all trucks transporting over-size or over-weight loads on all public roadways. For all loads over 10 feet wide traveling on SR 14 from east of the proposed Project Area between MP 76.77 and MP 76.91, use three pilot cars, two in front and one in the rear. The two front pilot cars would be required to maintain a minimum 500 feet of separation. The lead pilot car would warn oncoming traffic of the over-size load, and the pilot car immediately in front of the over-size load would be responsible for stopping all oncoming traffic.

• Design and build all access road improvements or new construction according to WSDOT and Washington State access management standards.

• Conduct pre- and post-haul construction visual assessments of roadway surface conditions to identify weak or deteriorated areas along the haul route that may require repair as a result of project-related traffic. Following the end of construction, repair all pavement sections affected by project-related traffic as needed to pre-construction conditions or better.

• Perform all snow removal from Project access roads in a safe manner that does not degrade roadway conditions.

3.11.4 UNAVOIDABLE ADVERSE IMPACTS

No major unavoidable adverse impacts to traffic and transportation have been identified. Construction of the Project is anticipated to have very minor impacts to LOS standards, and to have a potential very minor impact on traffic safety. Operation of the Project is anticipated to have little to no impact to transportation.

3.11.5 REFERENCES

3.12 PUBLIC SERVICES AND UTILITIES

This section describes impacts to public services and utilities. The Project Area is served by a variety of public services and utilities. Public services discussed include fire protection, law enforcement, emergency medical services and schools. Utilities discussed include telephone, electric, sewer, water and solid waste disposal.

3.12.1 AFFECTED ENVIRONMENT

3.12.1.1 Public Services

Fire Protection

As discussed in Section 3.6.1.2, Public Health and Safety, fire protection services are provided by two city fire departments (North Bonneville and Stevenson) and seven Skamania County fire districts provide fire protection to Skamania County residents. DNR also provides fire suppression services to forested areas in Skamania County, and would be the first responder to a fire emergency at the Project Area (J. Weeks, personal communication).

Law Enforcement

As discussed in Section 3.6.1.3, Public Health and Safety, the Skamania County Sheriff’s Office would provide law enforcement services to the Project. Sheriff’s Office headquarters are located in Stevenson, approximately 15 miles southwest of the Project Area. The response time from Sheriff’s Office headquarters to the Project Area is approximately 20 minutes.

Additionally, the Washington State Patrol patrols SR 14, which is south of the site. Construction and equipment delivery vehicles would travel on SR 14. Roads extending north of SR 14 are county roads, and are patrolled by the Sheriff’s Office.

Emergency Medical Services

As discussed in Section 3.6.1.4, Public Health and Safety, two ambulance companies would respond to an emergency in the Project Area: Skamania County Emergency Medical Service and Skyline Ambulance. Skamania County Emergency Medical Services is the functioning entity of Skamania County Hospital District No. 1, which provides ambulance service to the residents of Skamania County. Skyline Ambulance is based at Skyline Hospital in White Salmon, and is equipped with three ambulance vehicles.
The two hospitals closest to the Project are Skyline Hospital in White Salmon (7 miles southeast of the Project) and Providence Hood River Memorial Hospital in the City of Hood River (8 miles southeast of the Project).

**Schools**

The public school closest to the Project Area is the Mill A School, which is approximately 2 miles southwest of the site. The next closest public schools are in the community of Carson, approximately 10 miles west of the site. School buses may drive through neighborhoods near the Project Area, including Willard and Mill A, which are located approximately 2.25 and 1.5 miles respectively from the site.

Mill A School District No. 31 provides public educational services to the population in the district (ESD 2008). Mill A School currently enrolls 81 students in grades K through 8 in the southeastern corner of Skamania County adjacent to the Project Area. High school students living within the boundaries of the Mill A School District attend Stevenson High School in the Stevenson-Carson School District No. 303, which borders Mill A School District No. 31 on the west. Table 3.12-4 shows that over the last few years, enrollment in these five districts has not changed more than five percentage points, on average.

There are no higher education facilities near the Project Area. The higher education facilities closest to the site are located in Vancouver, Washington.

**3.12.1.2 Utilities**

The site area is served by the following utilities:

- Telephone: Embarq;
- Electric: Skamania County Public Utility District (PUD);
- Sewer: Individual septic systems;
- Water: Individual wells;
- Solid Waste Pickup: Skamania County.

Embarq provides telephone service to the area surrounding the site (D. Cox, personal communication). The Skamania County Public Utility District (PUD) is a customer-owned utility that provides electricity service to Skamania County. The PUD’s primary source of power is obtained from BPA, which markets power generated by the federal hydroelectric facilities along the Columbia River. The PUD’s backup power source is the Condit Dam. The PUD has expressed interest in using the Project as a source of backup power when the Condit Dam is removed.

The homes and businesses in Mill A and Willard do not have sewer service or water service, and are served by individual wells and septic systems.

Skamania County provides solid waste pick-up service to residences and businesses in the County, including those near the Project Area (Skamania County PUD office staff, personal communication). The majority of solid waste from Skamania County is delivered to the Roosevelt Regional Landfill in Klickitat County (WSSWIC 2009). The landfill began operations in 1990, and as of 2000 had in excess of 140 million tons of remaining permitted capacity. The landfill site contains more than 2,000 acres in which additional capacity could likely be permitted (Klickitat County 2000).

3.12.2 IMPACTS

3.12.2.1 Proposed Action

The potential impacts of the proposed Project on public services and utilities include those from construction and operation.

Construction

The use of construction workers from outside the immediate area could result in a minor and temporary increase in the demand for public services including police departments, providers of emergency medical services, and local fire departments.

The impact of Project construction on local schools would be at most minor and temporary, as few out-of-area construction workers are likely to be accompanied by families for this temporary construction project.

Construction-related impacts to local utilities providing telephone, electric or solid waste pickup are also expected to be minor and temporary. Most workers would not be in the area for long enough to obtain these services; those who stayed in temporary housing in the area would not remain for more than a few months.

The presence of construction vehicles on area roads would not impact the response times for emergency providers. Construction trucks would represent additional volume on area roads, but transportation LOS would remain at LOS A or B (delays of less than 15 seconds), and thus
would not cause substantial delays to emergency response vehicles. Construction activities themselves would take place entirely within land managed for commercial forestry by the Applicant, and would not impact local emergency providers.

Fire Protection

The Project Area is generally forest land. The only structures proposed on the forest lands are the towers, associated transformers and substation, and the Operations and Maintenance facility. Project construction could temporarily increase the risk of fire at the Project Area and in the broader Project Area. As the landowner, the Applicant has the ability to respond to fires on their forest land with dozers and water trucks.

Fire response on forest lands is provided by DNR. They have resources in the area and respond to all wildland fires. DNR would likely respond to a structure fire in the woods, as would Underwood Fire District and Mill A Volunteers. Mill A Volunteers is not a recognized fire district with a tax base but a volunteer fire company; the group has joint responder agreements with Underwood and DNR.

Underwood Fire District is the nearest local fire district and has submitted a comment (scoping comment #108) to EFSEC regarding their ability to respond to fires and provide services. The Underwood fire chief commented:

“The area designated for the energy project is outside our district; DNR is the official service provider for these areas. The Project may have a generally positive impact on the ability of our department and DNR to offer fire protection services to the area because new roads, extensions, and improved existing roads will provide better access for all first responders. If necessary, Fire District 3 can provide service coverage to the Project area without any reduction in service capacity to our constituency. We do not have a contract to provide service to the area. The project does not present any challenges or requirements for which we are not already prepared to respond.”

There are two potential locations for the Operations and Maintenance facility site, one on-site next to the substation and the alternative site along West Pit Road near the intersection with Willard Road. The alternative site would have a shorter emergency response time than the on-site option.

Law Enforcement

Construction activities associated with the Project would increase traffic volume on roadways surrounding the Project Area, as a result of both commuting construction workers and the transportation of materials. This increased volume would likely occur in mid-summer to fall when vacationers use the roadways. It is possible that the number of accidents and calls for service along major roadways (e.g., SR 14 and I-84) would increase for approximately six months, after which most of the on-site work would be done.

The demand for traffic enforcement activities would peak when construction employment peaks at approximately 265 employees for approximately one month. Out-of-area workers are not
expected to move their families into the Project Area because each construction phase requiring workers with specialized skills would be completed within three and one-half months or less. They would likely either commute (from the Portland-Vancouver area) or stay in temporary housing for the period of time needed to complete their tasks. As described in Section 4.4 Socioeconomics of the Application for Site Certification, this analysis assumes that as many as 40 non-local workers could be employed at the Project Area during the peak construction month (this includes potential out-of-state workers) and would likely stay in temporary housing.

There likely would be additional calls for response during the construction phase, primarily because of increased traffic and accident potential. However, because the construction period is short (approximately one year), the increased service calls are not anticipated to be sufficient in number to require additional law enforcement staff resources in the Project Area. See Section 3.11, Transportation, for further discussion of traffic safety hazards.

**Emergency Medical Services**

During Project construction, the local demand for emergency medical services could increase slightly due to construction accidents that could occur at the Project Area or Project vicinity. Project construction workers would be exposed to hazards caused by equipment failure, natural disaster, or human mistake that would require the services of local emergency response units to provide initial treatment and transportation to a local medical facility and the services of emergency rooms in the receiving facility. The specific level of demand for emergency medical service response is unknown.

With adequate safety measures in place, and considering the size of the construction workforce (which would temporarily reach a peak of 265 workers for one month) it is expected that Project construction would generate few serious injury accidents requiring emergency medical services response. The two local hospitals (Skyline Hospital in White Salmon and Providence Hood River Memorial Hospital in Hood River) have capacity for additional patients and there are ambulances available to service the Project Area.

It is expected that an average of 31 and a peak of 40 construction workers would temporarily migrate to the local labor market from either outside the immediate tri-county area of Skamania, Klickitat and Hood River region or from out of state. However, because the duration of their stay in the Project Area would be short (approximately four months), it is unlikely that these temporary workers would create a noticeable increase in demand for emergency medical services during Project construction.

**Schools**

An average of 21 (40 at peak) specialized non-local construction workers from out of the area would work on the Project. However, the anticipated maximum duration of employment for each craft is three to three and one-half months, and few workers are anticipated to move their families to the area. Further, much of the construction would take place during the summer months when school is not in session. Consequently, construction is expected to cause little to no additional enrollment. The Mill A and White Salmon School Districts have the capacity to handle any influx. The White Salmon Valley School District commented during scoping:
“Economically this project has the potential to benefit the community and the school district by adding revenues without creating additional demands for services or impacts on the school system.”

Construction traffic is not expected to lower transportation LOS below LOS A or B (delay less than 15 seconds), and consequently there would be little or no impact on school busses in the area.

**Utilities**

**Water Supply.** During the approximately one-year construction period, approximately 1.7 million gallons of water would be consumed for road compaction, dust control, wetting concrete, and other construction purposes. The construction contractor would supply water used during construction. Water would be delivered to the Project Area via water trucks and obtained from a local source with a valid water right. This impact would be negligible considering the temporary nature of the impact and the availability of adequate water supplies.

**Wastewater.** No impacts to community wastewater disposal systems are anticipated because the Project would not be connected to a sewer system during construction. Sanitary wastes would be collected in portable toilets during construction. Disposal of sanitary wastes would be managed through a contract with a portable toilet vendor. The contractor would incorporate applicable state capacity requirements based on the construction worker population in the Project Area at any given time. Collected wastes would be managed and disposed of by the contracted vendor.

**Solid Waste.** During construction, the primary wastes generated would be solid construction debris such as scrap metal, cable, wire, wood pallets, plastic packaging materials and cardboard. The total volume of construction wastes is expected to be less than ten tons. This waste would be accumulated on site in drop boxes until hauled away to a licensed transfer station or landfill by either the construction contractor or the Skamania County Solid Waste Division.

The majority of solid waste from Skamania County is delivered to the Roosevelt Regional Landfill in Klickitat County (WSSWIC 2009). The landfill began operations in 1990, and as of 2000 had in excess of 140 million tons of remaining permitted capacity. The landfill site contains more than 2,000 acres, in which additional capacity could likely be permitted (Klickitat County 2000).

**Operation**

Project operation would create a potential positive impact on public services and utilities. The Project’s assessed value could be as much as $87.5 million, and this would generate approximately $731,500 per year in property tax revenue and $50,000 in sales tax revenue. Assuming that an annual tax revenue of $731,500 would be distributed in the same manner as current property tax distributions, funds receiving the most revenue would be the State School Fund ($185,281), School District 405 Maintenance and Operations ($149,461), the County Road fund ($115,035), and the Current Expense fund ($111,086). The sales tax revenue would be split between Washington State (approximately $46,000) and Washington Counties, primarily Skamania and Klickitat Counties ($4,000). Section 3.13.2 Impacts provides additional
information on revenue. Although impacts are expected to be minimal, a portion of these funds could nevertheless be used to upgrade existing public services and utilities in Klickitat County.

The Project would have eight to nine on-site employees during operation. Given this small number, and considering the use of on-site services and emergency response plans, the Project is expected to have minimal adverse impact on local public services and utilities.

**Fire Protection**

Fire protection would continue to be provided by the Applicant, DNR, Underwood Fire District and Mill A Volunteers. Potential for fire during operations would be lower than during the construction period, and the remaining fire risk could be mitigated through appropriate operational practices. DNR has stated that resources for fire protection and suppression services are adequate to serve the Project during construction and operation (J. Weeks, personal communication).

Wildfires in the Project Area are relatively rare, and DNR continually monitors fire conditions.

Turbine fires are possible; however, with the types of modern wind turbines proposed for the Project, turbine malfunctions leading to fires in the nacelle are extremely rare. The turbine control system detects overheating in turbine machinery, and internal fires would be detected by these sensors, causing the machine to shut down immediately and send an alarm signal to the central supervisory control and data acquisition system, which would notify operators of the alarm by cell phone or pager.

**Law Enforcement**

The Sheriff’s Office resources are generally adequate to serve the Project during construction and operation, given that on-site security is provided by a separate party (D. Cox, personal communication). The Applicant would likely contract locally for private security.

**Emergency Services**

The Project would not result in a decrease in response times for area service providers during operation. The Project’s eight to nine permanent employees would not represent a substantial increase in traffic volumes on area roads that would impact emergency response, nor would Project facilities result in additional traffic controls.

**Schools**

The addition of eight to nine employees, even if all were from outside the local area and had families, would represent a minimal impact to local schools, especially since they would likely live in more than one school district.
Utilities

Upon completion, the Project and either of the proposed sites for the Operations and Maintenance Facility would be served by the following utility systems:

- **Telephone.** Embarq and Sprint. Both providers have adequate capacity to serve the site.

- **Electric service.** Skamania County PUD/BPA connection. Electricity would be used at the Operations and Maintenance building. The PUD has adequate capacity to serve the site. The impact would be the same at either alternative location for the facility; however, the alternative site at West Pit Road would be closer to existing PUD lines. No new BPA infrastructure would be needed for the electrical transmission interconnection system beyond the proposed interconnection and substation.

- **Drinking water.** Estimated water use during operation would be less than 5,000 gallons per day, primarily for showers, kitchen, and bathroom for Operations and Maintenance staff. Since the staff would work eight-hour shifts Monday through Friday, total water use is likely to be equivalent or less than a single-family home. Water would be supplied by an on-site well. A well using less than 5,000 gallons of water a day would be exempt from permit requirements in RCW 90.44.040. The well would be installed by a well contractor licensed pursuant to Chapter 173-162 WAC, and in compliance with the requirements and standards of Chapter 173-160 WAC. The well would be installed consistent with Skamania County Community Development Department and Ecology requirements for the new wells.

- **Wastewater.** Sewer service would be provided through an on-site septic system. The Operations and Maintenance facility would use less than 5,000 gallons per day of water, and since sewer flows are determined by indoor water use, total sewer flow is also likely to be equivalent or less than a single-family home. There is adequate space on either the Project Area or the alternative Operations and Maintenance site for construction of a septic field of sufficient size to serve this demand. The septic system would be built by a septic tank installer licensed by Skamania County, in accordance with all requirements of the Washington Department of Health and the Skamania County Community Development Department Environmental Health Division.

- **Non-hazardous waste.** Solid waste pickup would be provided by Skamania County through Allied Waste, which has one of three garbage collection franchises for the County. The Roosevelt Regional Land Fill has adequate space for any routine non-hazardous waste from the Project.

**Project Decommissioning**

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan would address site restoration that would occur at the conclusion of the Project’s operating life (estimated to be 30 years), and restoration in the event the Project is
suspended or terminated during construction or before it has completed its useful operating life. The plan would include or parallel a decommissioning plan for the Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential impacts on public services and utilities. If impacts to public services or utilities are anticipated to occur as a result of site restoration and Project decommissioning, mitigation measures would be proposed as part of the plan.

### 3.12.2.2 No Action Alternative

Under the No Action Alternative the proposed Project would not be built. There would be no impacts to public services and utilities.

### 3.12.3 MITIGATION MEASURES

The following mitigation measures are identified to avoid, reduce, or compensate for potential Project impacts to public services and utilities during construction or operation of the proposed Project.

- **Mitigate potential impacts to public services and utilities by using tax revenues generated by the Project.**

- **Provide all local police, fire, and emergency medical agencies with emergency response information for the Project, including employee contact information, procedures for rescue operations to the nacelles, and location of rescue basket.** The Applicant would provide applicable emergency response information to local agencies prior to Project construction and would review and update employee contact information annually and provide any changes to the appropriate agencies.

- **Utilize fire precautions for staying abreast of fire conditions in the Project Area by contacting DNR.** A Fire Protection and Prevention Plan would be developed for EFSEC approval and implemented, in coordination with the Skamania County Fire Marshall and appropriate agencies. Both the wind turbine generators and the substation would be equipped with lightning protection systems. As seen in Table 3.6-5, Public Health and Safety, sources for potential fire and explosion along with measures to mitigate the risk of either occurring, are outlined.

- **Maintain the use of a full-time security plan during Project construction to reduce the potential need for increased police services to the Project Area.** These law enforcement mitigation measures are outlined in Section 3.6.3, Public Health and Safety.

- **Prepare emergency plans to protect the public health, safety, and environment on and off the Project Area in the case of a major natural disaster or industrial accident relating to or affecting the Project.** The construction specifications would require that the contractors prepare and implement a Construction Health and Safety Program that included an
emergency plan. The Construction Health and Safety Program would include the following provisions:

- Construction Injury and Illness Prevention Plan;
- Construction Written Safety Program;
- Construction Personnel Protective Devices;
- Construction On-Site Fire Suppression Prevention; and
- Construction Off-Site Fire Suppression Support.

- Install the well supplying the Operations and Maintenance facility, at either of the two sites under consideration, by a well contractor licensed pursuant to Chapter 173-162 WAC, and in compliance with the requirements and standards of Chapter 173-160 WAC. The well would be installed consistent with Skamania County Community Development Department and Ecology requirements for the new wells.

- Coordinate and comply with the Skamania County Community Development Department Environmental Health Division, and would comply with all County and State septic tank and subsurface disposal field design, installation, and maintenance requirements

3.12.4 UNAVOIDABLE ADVERSE IMPACTS

The Project would have no unavoidable adverse impacts to public services and utilities. The small amount of additional services and utilities that would be needed would be offset by the increased tax revenue.

3.13 SOCIOECONOMICS

This section describes the potential impact of the proposed Project on local socioeconomic resources. For the purpose of this analysis, the region is defined as the tri-county area that includes Skamania and Klickitat Counties in Washington State and Hood River County in Oregon State. The Project Area is defined as the area within approximately three miles of the Project Area.
3.13.1 AFFECTED ENVIRONMENT

3.13.1.1 Demographics

Region

Table 3.13-1 shows the April 1, 2009 population for Skamania and Klickitat Counties, and the July 1, 2008 population for Hood River, Oregon. A greater percentage of all three counties live outside of incorporated areas. The incorporated cities closest to the Project Area are White Salmon, Washington, with 2,200 residents, and Hood River, Oregon, with 6,865 residents. The metropolitan area closest to the Project Area is the Portland-Vancouver-Beaverton metropolitan area, with a population of 2.2 million people. Table 3.13-1 also shows the population distribution for the region and the surrounding communities.

Minority residents represent 23 percent of the White Salmon population and 31 percent of the Hood River population. The minority population is primarily Hispanic/Latino. The tri-county area including Skamania, Klickitat, and Hood River Counties is predominantly white, non-Hispanic. Hood River County has the highest minority percentage (31 percent) of population, followed by Klickitat County (16 percent) and Skamania County (11 percent). The State of Washington population includes 24 percent minority residents. Oregon’s population includes 20 percent minority.

In 2000, 17 percent of the population of White Salmon and Hood River were living below the poverty level. This same measure was 13 percent for Skamania County, 17 percent for Klickitat County, and 14 percent for Hood River County the same year. These percentages are higher than statewide averages for Washington and Oregon.

Skamania County’s population is expected to grow from 10,800 in 2009 to 11,720 in 2015, an annual average growth rate of 1.4 percent. Klickitat County’s population is expected to grow from 20,200 in 2009 to 23,049 in 2015, an annual average growth rate of 2.2 percent. The growth rates for both Skamania County and Washington State are expected to slow by 0.3–0.4 percentage points during 2015 to 2025. The population growth rate for Klickitat County is expected to slow from 2.2 to 1.1 percent for 2015 to 2025. Skamania County is expected to have 12,915 residents by 2025 and Klickitat County is expected to have 25,831 residents by 2025. Hood River County is expected to grow 1.3 percent annually on average, during 2009–2015 and 2015–2025.

25The Census Bureau uses a set of income thresholds that vary by family size and composition to determine who is in poverty. If a family’s total income is less than the family’s threshold, then that family and every individual in it is considered in poverty. The official poverty thresholds do not vary geographically, but are updated annually for inflation. The poverty threshold in 2000 for a family of four with two related children under age 18 was $17,463 (US Census 2009).

Notes: 2000 estimates are April 1 estimates; 2009 estimates are April 1 for Washington State and counties, and July 1 for Oregon state and Hood River County.
Sources: WOFM (2009), PSUPRC (2009).

Project Area

In 2008 the three census block groups within 3 miles of the Project Area had 3,347 residents. Approximately 12 percent were minority. Twelve percent lived below the poverty level in 2008. Nine percent lived below the poverty level in 2000: higher than for the region generally.

Minority and Low-Income Populations

Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, states that each federal agency shall identify and address, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low income populations. The Order further stipulates that the agencies conduct their programs and activities in a manner that does not have the effect of excluding persons from participation in, denying persons the benefits of, or subjecting persons to discrimination because of their race, color, or national origin.

As stated above, the 2009 Census indicated that Skamania County had a minority population that consisted primarily of Hispanic/Latino persons which accounted for only 6 percent of the total
population in that county. Additionally, of the total population make-up for Skamania County, 12 percent were living below the poverty level as indicated by the 2008 Census.

3.13.1.2 Housing

Region

In 2008 there were 5,409 housing units in Skamania County, 9,985 housing units in Klickitat County and 3,050 housing units in Hood River County. Occupancy rates in 2008 were 83 percent in Skamania County, 89 percent in Klickitat County and 90 percent in Hood River County, representing 909 vacant units in Skamania County, 1,078 vacant units in Klickitat County and 892 vacant units in Hood River County. In 2000, median gross rents were 13 percent lower in Skamania County and 25 percent lower in Klickitat County than for Washington as a whole. Median gross rent in Hood River County was 13 percent lower than in Oregon as a whole in 2000.

Project Area

The existing residences closest to the Project Area are approximately 0.48 mile and 0.8 mile from the proposed turbine locations. A new homesite location has been applied for, which would be located approximately 2,000 feet (0.38 mile) from the site’s south property line. It is unknown if the applicant for this permit has secured all approvals or has proceeded with construction plans. One of two alternative Operations and Maintenance facility sites is located approximately 0.9 mile west of the Project Area on West Pit Road. The nearest residence to this potential site is approximately 0.25 mile away. The other alternative Operations and Maintenance facility site is located in the Project Area adjacent to and north of the substation, farther from residential areas.

The unincorporated community of Willard is located approximately 2.25 miles northwest of the Project Area. The unincorporated community of Mill A also is located near the Project Area, approximately 1.5 miles west of the site. The homes near the Project Area are in a rural setting, primarily single family and between 30 and 50 years old.

Temporary Housing

Over 1,000 hotel rooms and 39 recreational vehicle (RV) or tent campsites exist within 25 miles of the Project Area (Table 3.13-2). Assuming an average occupancy rates of 70 percent, a minimum of 325 hotels rooms or RV/tent campsites are available at any one time.

3.13.1.3 Employment

**Region**

In Skamania County, there were approximately 3,254 jobs in 2007 (BEA 2009), representing a gain of 138 jobs over 2006 levels. The principal sources of employment in Skamania County were local government, accommodation and food services, federal government, and manufacturing (Golubcow 2006a and 2006b). “Place of work earnings” (wages, salaries and proprietors’ earnings) accounted for only one-quarter of total personal income in the county, with income from property (dividends, interest and rent) and transfer payments (mainly Social Security) making up the balance. The annual unemployment rate in Skamania County was 6.6 percent in 2007 and 8.4 percent in 2008, higher than for Washington State (4.5 percent in 2007 and 5.5 percent in 2008).

In Klickitat County, there were approximately 9,839 jobs in 2007 (BEA 2009). Of these jobs, SDS and Broughton Lumber Company employ a work force of up to 325 employees during their busiest production times, which is equivalent to three percent of total jobs in Klickitat County. The principal sources of employment were local government, retail trade, and professional and technical services. Place of work earnings accounted for about 46 percent of total personal income in the county, with income from property and transfer payments making up the balance. The unemployment rate in 2007 was 6.7 percent, and in 2008 was 8.2 percent. These unemployment rates were higher than for Washington State as a whole.

There were 15,787 jobs in Hood River County in 2007 (BEA 2009), representing the highest employment of the three counties in the region. Place of work earnings accounted for 59 percent of total personal income in the county, with income from property and transfer payments making up the balance. The principal sources of employment were manufacturing, health care and social assistance, local government, and retail trade. The unemployment rate in Hood River County was 4.6 percent in 2007. In comparison, the annual unemployment rate for Oregon as a whole was 5.1 percent in 2000 and 5.2 percent in 2007.

---

26 Located in Bingen, SDS jobs are reported as part of Klickitat County statistics even though logging operations occur in both Skamania and Klickitat Counties.
Table 3.13-3 shows unemployment rates in the region for 2000, 2007 and 2008. Hood River County has the lowest unemployment rate of the three counties in the region. The most recent available annual unemployment rate in Hood River County (2007) is roughly two percentage points lower than the same measures for Klickitat and Skamania Counties and 0.6 percentage point lower than for Oregon as a whole.

* The most recent annual statistics for Washington are for 2008 and are shown in this column. The most recent annual statistics for Oregon are for 2007. This column shows (for the Oregon areas) the most recent unemployment rate available for both Oregon and Hood River County, which is the December 2008 monthly unemployment rate.

The annual rates, however, do not show the impact of the economic recession, which began to be felt at the end of 2008. These effects can be partially seen by comparing monthly unemployment rates between 2008 and 2009 (through August, the latest month available) which are shown in Table 3.13-4. Table 3.13-4 shows that in August 2009, Skamania County’s unemployment rate was 3.1 percentage points higher than for the same month in 2008. The comparable figures are 2.9 percentage points for Klickitat County and 3.3 percent for Hood River County.

Project Area

The Project Area is used for long-term timber production. Although the number of jobs in the project area is unknown, approximately 400 homes or businesses exist within three miles of the Project Area, and approximately one-third of these homes or businesses are located in Willard.

Minority and Low-Income Populations

Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, states that each federal agency shall identify and address, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low income populations. The Order further stipulates that the agencies conduct their programs and activities in a manner that does not have the effect of excluding persons from participation in, denying persons the benefits of, or subjecting persons to discrimination because of their race, color, or national origin.

As stated above, the 2000 Census indicated that Skamania County had a minority population that consisted primarily of Hispanic/Latino persons which accounted for only 11 percent of the total.
population in that county. Additionally, of the total population make up for Skamania County, 13 percent were living below the poverty level as indicated by the 2000 Census.

### 3.13.1.4 Public Finance and Fiscal Conditions

Due to the location of the proposed Project within Skamania County and Washington State, these two jurisdictions would be the primary beneficiaries of tax revenues related to Project construction and operation. Washington State and Skamania County collect several types of taxes:

- **Payroll taxes.** Washington State collects payroll taxes for workers’ industrial insurance, unemployment compensation, and other purposes. While Counties do not directly benefit from payroll taxes, these revenues have a direct beneficial impact to Skamania County residents.

- **Business and occupation taxes.** Business and occupation taxes, which are paid on the gross receipts of business activities, are the second-largest revenue source for Washington State. Skamania County does not levy a business tax, so although it does not benefit directly from Business and occupation taxes paid by businesses within Skamania County, the state as a whole would benefit.

- **Retail sales and use tax.** In Washington State, the first 0.5 percent of retail sales tax goes to the local county.

- **Property tax.** Skamania County collects property taxes for taxing districts within the County. The Project Area is within Taxing District 109, for which the total assessment rate is $8.026839/$1,000 assessed value. This revenue is split between the County, Washington State, and the local taxing district.
In 2008, Skamania County started with a beginning fund balance of $25.6 million, and accrued revenues of $13.7 million that year. The largest revenue fund categories were intergovernmental revenues (43 percent), general property taxes (21 percent) and charges and fees for services (10 percent). Expenditures in 2008 were $19.4 million. The largest expenditure categories were law and justice services (26 percent), general government (20 percent), transportation (19 percent) and natural resource (10 percent) (Table 3.13-5).

Dollars in each of the revenue and expenditure categories are distributed among the General Fund, Special Revenue Fund, Debt Service Fund, Capital Project Fund and Enterprise Fund. Approximately 54 percent of all revenue dollars are in the General Fund, and 39 percent of the revenue dollars are in the Special Revenue Fund. Most of the expenditure dollars were in the General Fund (57 percent) and the Special Revenue Fund (37 percent).

The Project Area is within Taxing District 109, for which the total millage rate\(^27\) is $8.026839/$1,000 assessed value. The millage rate is broken down in Table 3.13-6.

### 3.13.2 IMPACTS

#### 3.13.2.1 Proposed Action

Impacts of the proposed Project are divided between construction and operation.

**Construction**

**Business and Economic Impacts**

Design and construction of the proposed Project is expected to begin in 2011. Operation is expected to commence by 2012. During the estimated one-year construction period (excluding engineering, design, specifications, and survey), approximately 330 full-time and part-time workers would be employed at some point during construction. Some of these jobs would not last the entire construction period. The on-site construction work force would peak at approximately 265 workers over the construction period and average 143 workers over the 12 months (Table 3.13-7).

An estimated 65 to 75 percent of the construction labor force would likely be hired from outside the tri-county area, and 25 to 35 percent would be residents of the tri-county area including Skamania, Klickitat, and Hood River counties (A. Barkley, personal communication).28 (This estimate is based on the relative size of the labor force in the tri-county area compared to larger labor forces in metropolitan areas that are farther away.) This would translate to 66 to 93 (peak)

---

28This information, along with estimated average and peak workforce size and number of full-time and part-time jobs related directly to project construction, are project-specific estimates provided by the Applicant.
and 36 to 50 (average) workers from the tri-county area and 172 to 199 (peak) and 93 to 107 (average) workers from outside the tri-county area, primarily the Portland-Vancouver metropolitan area. At peak, the construction workforce would represent 32 to 45 percent of the estimate size of the construction workforce in Skamania County in 2007 (BEA 2009).

Source: A. Barkley (personal communication)

The total cost of construction is $150 million. Total payroll costs, including fringe benefits and other labor overhead costs, are projected to be approximately $18 million, of which approximately $4.5 million (25 percent) is expected to be earned in the tri-county area (A. Barkley, personal communication), based on the assumption by the Applicant that approximately one-quarter of the construction workforce would already live in the tri-county area.

Non-labor costs are estimated to be $132 million. Construction materials, services and equipment leasing associated with construction are projected to total approximately $13.2 million (10 percent of total non-labor costs) (A. Barkley, personal communication). The Applicant estimates that most of this spending would take place in the tri-county area.

Spending by suppliers, local Project workers and households would benefit the retail trade and services sector, as well as other sectors of the local economy. To estimate the value of these indirect and induced impacts, assumptions specific to Project construction were provided by the proposed Project owner (A. Barkley, personal communication), and were used as inputs to the IMPLAN regional input/output model. These assumptions are as follows and were also mentioned above:
• Local non-labor construction expenditures would be approximately $13.2 million;
• Labor income earned by local residents would be approximately $4.5 million;
• Approximately one-quarter of the workforce (36 workers, taken as a percentage of the average workforce size of 143 workers) would be current residents of the local area.

Based on these assumptions and using IMPLAN modeling software, indirect and induced value added from construction is estimated to be approximately $3.9 million. Project construction would result in 71 indirect and induced jobs (Table 3.13-8). Total direct, indirect and induced value added would be an estimated $8.5 million. Total employment (direct, indirect and induced) would be an estimated 107 full-time and part-time jobs. These effects would continue throughout the construction period.

North American Industry Classification System categories that are 0 are not shown.
* Totals may not add due to rounding.

Economic effects would occur beyond the tri-county area in the form of jobs, income and spending. These effects would occur due to spending (attributable to Project construction) that would occur outside the tri-county area. Although these effects were not quantified as part of this analysis, 65 percent to 75 percent of the construction workforce would live in areas outside the tri-county area; therefore, spending would likely increase in the areas where these employees reside. Also, non-labor construction procurements that occur in areas outside the tri-county area (estimated to be approximately $119 million) would result in economic benefits. Areas that benefit could include the metropolitan area closest to the proposed Project (Portland-Vancouver) as well as other areas in the Northwest and the nation as a whole.

29 Value added is the difference between the proposed project’s total output and the cost of the proposed project’s inputs. For the construction industry in the tri-county area, value added is comprised primarily of employee compensation (IMPLAN 2008). Value added is a measure of the contribution to output in the tri-county area made by project construction.
Population and Housing Impacts

Up to an estimated 15 percent of the construction workforce would be specialized craftsmen originating outside of Washington and Oregon (A. Barkley, personal communication). These workers would likely have relatively short assignments, and few would be expected to bring their families to the area. The remaining 85 percent of non-local workers would likely come from the Portland-Vancouver area. Assuming as a worst-case scenario that one-third of the workers from the Portland-Vancouver metropolitan area would stay in temporary lodging near the Project Area Monday through Friday, and the specialized, temporary staff also would require lodging, the population that would require housing in the tri-county area is expected to range from 75 workers to 85 workers during peak construction. These construction workers would be expected to seek temporary accommodation in the general vicinity of the Project Area, and to use motels, trailers, campers, and other forms of transient housing. Given that 325 of the approximately 1,082 hotel rooms or RV campsites within 25 miles of the Project Area would be available at any one time, the out-of-area workers would not cause a substantial impact to the availability of transient accommodation in the Project vicinity. The construction phase of the proposed Project is not expected to affect median housing values, median gross rents, or new housing construction.

Fiscal Impacts

Overall fiscal impacts of Project construction are expected to be positive, based primarily on increased employment and spending in the local economy.

Sales Tax Revenue. The total cost of construction is estimated to be approximately $150 million. Non-local procurements would include wind power generation equipment purchased from various domestic and foreign suppliers. Depending on legislation currently under consideration in the state legislature, state sales and use tax may be levied only on procurements that are not directly related to electricity generation. Should the state sales tax exemption for wind power be extended, capital equipment such as turbines, transformers, transmission cables, and substation equipment would not be taxable.

Local procurements are estimated to be 10 percent of total procurements ($13.2 million) (A. Barkley, personal communication). An estimated 90 percent of local procurements would be directly related to electricity generation, and would not be subject to sales tax should the state sales tax exemption for wind power be extended. Taxable sales due to Project construction is therefore estimated to be approximately $1.32 million, resulting in $92,400 in sales and use tax revenue using the sales tax rate (7.0 percent) for the Project Area, which is located in unincorporated Skamania County.

Most of the sales tax revenue due to Project construction would accrue to Skamania County because the Project Area is located in Skamania County. However, if taxable construction supplies are purchased in another Washington State county (Klickitat County, for example), and not shipped to the Project Area, the county in which the purchase occurred would receive the county portion of the sales tax revenue on that purchase. Of the total estimated $92,400 in sales tax revenue, Washington State would receive $85,800 and Skamania County (or the counties where materials or supplies are purchased and not shipped to the site) would receive $6,600.
If a portion of taxable construction materials or supplies are purchased in Hood River County, the owner must pay use tax to Washington State, in which case the tax would go to Washington State (6.5 percent) and Skamania County (0.5 percent). Sales tax revenue would not accrue to Hood River County. Klickitat County could receive a portion of the sales tax revenue, but as stated above, the majority of the county portion is expected to go to Skamania County.

In addition to the $92,400, the proposed Project would result in modest increases in sales tax revenues due to local purchases by construction workers.

**Property Values and Property Tax Revenue.** Construction activities are not likely to adversely affect property values in residential and commercial areas near the Project Area because the construction period would be relatively short. Construction of the proposed Project would not affect property tax revenues.

**County Expenditures.** Construction of the proposed Project would require that many construction vehicles, including trucks with over-size and over-weight loads, share the existing roadway network with the general public. Skamania County could experience a small increase in traffic-related costs due to the need for permitting and control measures related to these vehicles, particularly for the over-size loads. Some accidents could occur that would be directly attributable to construction traffic, but any increase is expected to be minimal.

The County could experience minor to negligible increases in the cost of public services such as fire suppression, law enforcement, governmental services, parks and recreation, and hospital costs during construction due to the additional traffic and the temporary population. These are not expected to be significant in the context of the County as a whole.

**Operation**

**Business and Economic Impacts**

Operation of the proposed Project would result in a positive economic impact to Skamania County, the tri-county area, and the State of Washington due to increased tax revenues, employment, and local expenditures.

Project operation would require eight to nine full-time or part-time Operations and Maintenance employees. Approximately 75 percent of employees (7 employees) would originate from the tri-county area (A. Barkley, personal communication). An additional temporary workforce with appropriate skills would be utilized during major maintenance or other non-routine operational work. Efforts would be made to hire local individuals to staff the proposed Project as much as practicable.

The estimated gross payroll, including fringe benefits and other payroll overhead for the operational workforce would be $1.5 million, or an average annual labor cost of $167,000 to $188,000 per employee. Subtracting approximately 25 percent to estimate benefits and overhead, the implicit wage would be within 10 percentage points of the 2007 standard industrial wage for construction workers in Skamania County (IMPLAN 2009).
In addition to the direct employees, Project operation would result in indirect and induced employment, for an estimated total of 11+2 permanent jobs resulting from the proposed Project (Table 3.13-9).

Source: IMPLAN (2009).  
North American Industry Classification System categories that are 0 are not shown.  
a Totals may not add due to rounding

Using IMPLAN regional economic modeling software for the power generation and supply industry in Skamania, Klickitat, and Hood River Counties, a wind power facility employing nine full-time workers would have a gross annual operating cost valued at approximately $3.75 million. This would include direct purchases from suppliers (including fuels, maintenance supplies and services, retail goods and professional services).

An alternative methodology for calculating job impacts is used by the Renewable Energy Policy Project, which estimates that every megawatt of installed wind capacity creates about 4.8 job-years of employment, including both direct and indirect jobs (REPP 2009). Using this methodology, the proposed Project, which would produce approximately 75 MW of electricity, would result in 360 job-years or 12 jobs per year for the 30 year life of the proposed Project.

As stated in Chapter 1, the purpose of the Project is to help meet the future need for energy resources while at the same time enabling SDS to further diversify its business through a technically and economically feasible project. When SDS started in 1946, there were 26 employees in its original crew. This number grew to a high of 450 employees during the 1970s when logging and lumber production were at a peak. Production has since slowed tremendously, as the supply of timber from national forests has sharply declined due to environmental legislation. For this reason, many of the mills in Skamania County have closed down. SDS was able to survive the crises and changes of the last 30 years and no longer relies on timber from...
national forests. SDS has scaled back operations, yet today SDS is one of the largest employers in Klickitat County, employing 325 people during busiest production times.

SDS has remained viable during changes in the market through expanding and diversifying its enterprises to include marine in 1984 and power produced in its steam-operated power plant, which creates energy from wood waste, a renewable, organic resource. The Project is intended to provide another means of diversifying the holdings of SDS to ensure a continuation of a resource-based work force in Skamania County, and to create new construction and operation jobs at a time when jobs in Washington State are being lost. As shown in Table 3.13-9, the proposed Project would create twelve new full-time jobs in Skamania County.

Population and Housing Effects

Of the nine permanent employees for the proposed Project, seven are assumed to originate from the tri-county area, and two would be assumed to migrate to the area from other locations. Assuming an average household size of 2.6 persons, the population in the area could increase by approximately five people, and two households. At the most recent average housing vacancy rate available for Skamania County (16.8 percent), more than 900 housing units would be available in Skamania County alone. Thus operation of the proposed Project would not impact housing availability or cost.

The proposed Project would not displace any minority or low-income populations. The proposed Project would be constructed on private land currently used for forest production, and no residents would be displaced.

Fiscal Impacts

Property Values. Local communities near proposed wind turbine locations have expressed concern that constructing wind turbines would detract from views, which would in turn decrease their property values. A number of studies have been performed to determine the impact of wind power projects on property values. These include the following:

- The Lawrence Berkeley National Laboratory prepared *The Impact of Wind Power Projects on Residential Property Values in the United States: A Multi-Site Hedonic Analysis* in December 2009 (Hoen et al. 2009). Researchers collected data on almost 7,500 sales of single-family homes within 10 miles of 24 existing wind facilities in nine different US states. None of the models uncovered conclusive evidence of the existence of any widespread property value effects that might be present in communities surrounding wind energy facilities. Neither the view of the wind facilities nor the distance of homes to those facilities was found to have any consistent, measurable, and significant effect on the selling prices of those homes (Hoen et al. 2009).

- In 2006, ECONorthwest prepared *Economic Impacts of the Kittitas Valley Wind Project* (the Kittitas Study) for the Economic Development Group of Kittitas County, Washington. This report involved a survey of tax assessors in counties (other than Kittitas County) with wind projects to determine the potential effects of wind facilities on property values. The Kittitas Study also conducted a review of the available academic literature for additional information on property value effects. The finding was that...
views of wind turbines would not negatively impact property values (ECONorthwest 2006).

- The Renewable Energy Policy Project prepared *The Effect of Wind Development on Local Properties* (REPP 2003). For this study, the project compiled a database that included every wind development that came online after 1998 with 10 MW installed capacity or greater. For all projects for which sufficient data was available, REPP conducted a statistical analysis to determine how property values changed over time in the viewshed and in the comparable community. The statistical analysis provided no evidence that wind development has harmed property values within the viewshed (REPP 2003).

- Responses to comments published as part of the 2009 Desert Claim Wind Power Project Final Supplemental Environmental Impact Statement state “the Final EIS referenced a 2003 report published by Kittitas County that summarized the existing literature on the effect of wind power projects on property values.” The response states that the study, which was prepared by Huckell/Weinman Associates, concluded that wind power facilities have not diminished the value of surrounding properties (EFSEC 2009).

- A literature review to assess the question of whether wind turbines in rural communities have the potential to affect residential property values was completed as part of the Lower Snake River Wind Energy Project Draft EIS (Ecology & Environment 2009). The Draft EIS reported that in 2008 Hoen and Wiser found (1) no statistical evidence that homes near wind facilities are stigmatized by those facilities, (2) no statistical evidence that homes with a view of wind turbines have different values than homes without such views, and (3) no statistical evidence that homes within 0.25, 0.5 and 1 mile of the turbines sell for different values than those located further away. In 2006, while assessing the impacts of a 20 turbine, 30 MW wind facility’s visibility on residential property values in Madison County, New York, Hoen found no statistically significant relationship between either proximity to or visibility of the wind facility and the sale price of homes (Ecology & Environment 2009, Hoen 2006).

In summary, the results of these studies and literature reviews are that no statistical evidence exists that wind development has a harmful effect on property values within the viewshed. Therefore, property value impacts are not expected as a result of the proposed Project.

**Sales Tax Revenues.** Sales, use and other indirect business taxes to state and local governments attributable to Project operation are estimated at approximately $50,000 per year. This estimate is the sum of the estimated sales and use tax revenue from (1) the procurement of supplies and materials for the purpose of Project operations, and (2) new employee spending in the area. The sales tax revenue would be split between Washington State (approximately $46,000) and Washington counties, primarily Skamania and Klickitat counties ($4,000).

The portion of non-labor annual operating cost that is not directly related to electricity production (10 percent of $2.3 million, or approximately $230,000) would be taxable (A.
Barkley, personal communication). Applying the Skamania County sales and use tax rate (7.0 percent) to this amount results in an estimated $15,800 in tax revenue.

New employee spending is estimated by taking the total labor income (direct, indirect, and induced) from the IMPLAN operations model (approximately $977,000 per year) and assuming that 70 percent of this amount is disposable income and 70 percent of disposable income is spent in local Washington counties. Based on these assumptions, related sales and use tax revenue would be approximately $34,000.

With the proposed Project, the Project Area would continue to be managed as commercial forest, excluding the area containing the turbine strings and roads. The Project Area covers 1,152 acres. Table 1-1 shows that the maximum area developed for the wind turbine foundations, connecting roadways and transmission lines would be 384 acres (approximately 33 percent of the 1,152-acre site). As specific locations are determined for turbines and other Project components, the 384-acre area would be reduced. The areas that would experience permanent impacts and temporary construction impacts of the proposed Project total approximately 108 acres (approximately nine percent of the 1,152-acre site). The 56-acre area that would be removed from timber production for the life of the proposed Project is approximately five percent of the total Project Area. The opportunity cost of taking this land out of timber production would include tax revenues for Skamania County and Washington State, and would be countered by the sales tax revenues resulting from wind energy sales.

**Property Tax Revenue.** The proposed Project would have an estimated value of $87.5 million, which would represent an increase of 6.5 percent in assessed value in the County. Using the average 2008 property tax rate for Skamania County of $8.36/$1,000 assessed value (WDOR 2009), the increase in property tax revenue to the County would be $731,500. This would represent an annual revenue increase of 2.9% over 2007. Although Washington State limits property tax increases to one percent of the previous year’s levy, new construction does not apply, and would be added on after the one percent is added, using the previous year’s property tax rate (V. Torres, personal communication). The increase in property tax revenue would begin one year after construction is complete, and continue for the life of the proposed Project. However, to the extent the wind turbines depreciate over time, the assessed value of the turbines and therefore the property tax revenue also would decrease.

Additional property tax revenue would be distributed to a variety of County departments. Assuming that annual tax revenues of $731,500 would be distributed in the same manner as current property tax distributions, funds receiving the most revenue would be the State School Fund ($185,281), School District 405 Maintenance and Operations ($149,461), the County Road fund ($115,035), and the Current Expense fund ($111,086). A portion of the State School Fund would be returned to Skamania County for Skamania County schools.

Property tax revenues would be higher to the extent that increased wages and economic activity in the County resulted in higher valued properties.

A different methodology was used by the National Wind Coordinating Committee, which estimates an increase of $10 to $14 in property taxes for each $1,000 investment (NWCC 2009).
Using this approach, the $17.7 million dollars spent locally (labor and non-labor cost) would result in approximately $177,000 to $250,000 in additional property taxes. This estimate is lower than the forecast given above; however, the NWCC estimate is based on industry averages, while the first estimate is based on project-specific data.

**County Services.** The addition of five residents would cause a negligible increase in demand for and cost of public services. These would also be outweighed by the substantial economic benefits of the proposed Project to the County.

**Minority and Low-Income Populations.** Environmental justice addresses whether the Proposed Action would disproportionately impact disadvantaged populations such as low-income and minority residents. The population in the study area (Skamania and Klickitat Counties, Washington; and Hood River County, Oregon) is predominantly white (non-Hispanic/Latino) and a review of data from the 2000 Census did not identify any specific geographic concentrations of minority groups. The Proposed Action would not be expected to disproportionately affect any low-income populations, based on per capita income information at the Census Tract level. Therefore, there would be no disproportionately high or adverse effects to minority or low income groups.

**Project Decommissioning**

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant would provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. **A detailed site restoration plan is required within ninety days of Project decommissioning.** The initial site restoration plan would address site restoration that would occur at the conclusion of the proposed Project’s operating life (estimated to be 30 years), and restoration in the event the proposed Project is suspended or terminated during construction or before it has completed its useful operating life. The initial site restoration plan would include or parallel a decommissioning plan for the proposed Project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major socioeconomic issues presently anticipated, including potential impacts to population, housing and employment. If socioeconomic impacts are anticipated to occur as a result of site restoration and Project decommissioning, mitigation measures would be proposed as part of the plan.

**3.13.2.2 No Action Alternative**

Under the No Action Alternative, the proposed Project would not be built. Socioeconomic conditions in the area would continue in their present condition.

**3.13.3 MITIGATION MEASURES**

The following mitigation measures are identified to avoid, reduce, or compensate for potential Project impacts to any socioeconomic factors during construction or operation of the proposed Project.
• Impact to the local economy and social structure of the proposed Project is expected to be beneficial, in the form of additional jobs, increased sales, and increased tax revenues. Temporary increases in population during construction are likely to be minor in view of the availability of housing, transient accommodations, and other public services in the region.

• Ensure that the applicant uses the local labor pool to the greatest extent possible; construction contractors would be required to advertise positions locally and to employ local workers to the greatest extent possible.

3.13.4 UNAVOIDABLE ADVERSE IMPACTS

The proposed Project would result in beneficial impacts, primarily from employment during construction and operation. Minimal adverse impacts are expected.

3.14 CUMULATIVE IMPACT ANALYSIS

“Cumulative impacts” are the impacts on the environment which result from the incremental impact of an action, such as this Proposed Action, when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (federal or non-federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 C.F.R. 1508.7).

This section describes existing development in the vicinity of the proposed Project, as well as current and reasonably foreseeable future development planned for the area, and analyzes and describes potential cumulative impacts. The past, present, and reasonably foreseeable future actions provide the context to assess the cumulative impacts of these actions in combination with the Proposed Action.

3.14.1 EXISTING DEVELOPMENT

The nature and extent of existing development in the vicinity of the proposed Project (i.e., generally within approximately 20 miles of the Project Area) is largely described earlier in this chapter in the sections for each environmental resource. This section first summarizes existing cumulative development that has occurred in the vicinity of the proposed Project. This section then discusses existing wind projects that are considered in the analysis of potential cumulative visual impacts to travelers and others along the I-84 corridor.

3.14.1.1 Surrounding Land Uses

The general Project vicinity is characterized by agriculture, commercial forestry, rural residential development, and a small number of commercial enterprises.
The proposed Project Area is located approximately two miles north of the Columbia River and directly north of the Columbia River Gorge National Scenic Area. The National Scenic Area extends along the Columbia River for about 85 miles and includes 292,500 acres in parts of three Oregon and three Washington counties. Although both the Project Area and the proposed access road are located completely outside the Scenic Area, the proposed Project Area does extend south to the northern boundary of the Scenic Area. The Gifford Pinchot National Forest is located north of the Project Area.

On the Washington side of the Columbia River, land use is predominantly commercial forestry and residential in numerous small, unincorporated communities. There are approximately 400 residences and businesses within three miles of the Project Area (Figure 3.8-1). There is some limited agriculture, mostly pear and apple orchards recently augmented with some wine grape vineyards, located within the Columbia River Gorge National Scenic Area. On the Oregon side of the Columbia River, land use within the Scenic Area is predominantly commercial timber production and residential. South of the Scenic Area, land uses include commercial forestry, agriculture, and some residential. The primary Oregon orchard crops are pears, apples, and cherries.

3.14.1.2 **Existing Wind Projects**

Portions of the Project would be visible to drivers along I-84, which is located on the Oregon side of the Columbia River. For the purpose of assessing cumulative impacts to visual resources, views of other wind projects from I-84 were considered even if they are located farther than 20 miles from the Project Area. I-84 extends for a distance of approximately 130 miles from Cascade Locks, Oregon (southwest of the Project Area on the Oregon side of the Columbia River) to the intersection with I-82, which leads north to the Tri-Cities. The draft EIS identified ten existing wind projects along this segment, all located within a distance of approximately 70 miles east of the Project Area (to approximately Arlington, Oregon). Following publication of the draft EIS, eight additional wind projects were identified within a distance of approximately 70 miles east of the Whistling Ridge Energy Project Area. These projects have been added to the analysis in the FEIS. These 18 projects could potentially be viewed by drivers along I-84 within a driving time of approximately one to one-and one-half hours and were included in the analysis of cumulative impacts to Visual Resources described further in Section 3.14.3.10. These ten projects could potentially be viewed by drivers along I-84 within a driving time of approximately one to 1.5 hours.

From Arlington, I-84 continues on in an easterly and the southeasterly direction, terminating at Pendleton, Oregon. There are no existing wind energy projects in this area. Farther east, there are wind energy generation projects southeast of the Tri-Cities, and west and southwest of Walla Walla (in both Washington and Oregon), more than 80 additional miles east-northeast. These were considered too remote for this analysis.

All of the ten existing wind energy projects considered in the cumulative visual resource impact analysis are located east of the Columbia River Gorge National Scenic Area as shown in

---

Figure 3.14-1. Nine four are located north of the Columbia River in Washington, and nine six are located south of the river in Oregon. In contrast to the steep terrain and forested vegetation of the Project Area, the 18 ten operating wind projects located to the east are on lands with rolling hills, open vistas, and little or no vegetation. The projects that were considered include:

- Windy Point (Tuolumne), 137 MW wind project west of Maryhill, Washington;
- Windy Flats – Dooley, 113 MW wind project west of Maryhill, Washington;
- Linden Ranch, 50 MW wind project near Goldendale, Washington;
- Goodnoe Hills, 94 MW wind project north of the Columbia River between Goldendale and Roosevelt, Washington;
- White Creek, 205 MW wind project near Roosevelt, Washington;
- Harvest Wind, 99 MW wind project near Roosevelt, Washington;
- Juniper Canyon I, 150 MW wind project in Klickitat County, Washington;
- Big Horn, 199 MW wind project in Klickitat County, Washington;
- Big Horn II, 50 MW wind project in Klickitat County, Washington;
- Patu, 10 MW wind project near Wasco, Oregon;
- Biglow Canyon (I, II, III and Phase II), 600 425 MW wind project in Sherman County, Oregon;
- Klondike (I, II, III HHA), 499 MW wind project in Sherman County, Oregon;
- Hay Canyon, 101 MW wind project in Sherman County, Oregon;
- Goodnoe Hills, 94 MW wind project north of the Columbia River between Goldendale and Roosevelt, Washington;
- Big Horn, 199 MW wind project in Klickitat County, Washington;
- Star Point, 99 MW wind project in Sherman County, Oregon;
- White Creek, 205 MW wind project near Roosevelt, Washington;
- Wheat Field, 97 MW wind project near Arlington, Oregon;
- Rattlesnake Road, 103 MW wind project near Arlington, Oregon;
- Wheat Field, 97 MW wind project near Arlington, Oregon;
• Leaning Juniper I, 150 MW wind project near Arlington, Oregon;
• Leaning Juniper II, 200 MW wind project near Arlington, Oregon;

3.14.2 REASONABLY FORESEEABLE FUTURE DEVELOPMENT

Reasonably foreseeable future development generally includes those actions currently underway, formally proposed or planned, or highly likely to occur based on available information. Reasonably foreseeable future development projects located within approximately 20 miles of the Project Area were identified to determine if they could potentially have cumulative impacts on the environment, including water quality, soil erosion, vegetation, terrestrial wildlife species, and bird and bat species. The 20 mile radius was considered a reasonable geographic area within which to consider potential cumulative impacts, particularly construction-related impacts such as surface disturbance, vegetation removal, emissions, runoff, noise, and traffic. To assess potential cumulative visual impacts to drivers along the I-84 corridor, reasonably foreseeable future wind projects located within approximately 70 miles of the Whistling Ridge Project Area were also added to the analysis.

Various sources, including searches in the fall of 2009 of the web sites of the surrounding Skamania, Klickitat and Hood River Counties, Columbia River Gorge Commission, WSDOT, Oregon Department of Transportation, EFSEC, the Oregon Department of Energy, and the Ports of Skamania County, Klickitat County, The Dalles, and Cascade Locks, were made to obtain information about any current and potential future development in the Project vicinity. Reasonably foreseeable development that may occur in the vicinity of the Proposed Action could include both other wind projects and roadway projects. (See Figure 3.14-1 for the general locations of this potential development.)

Both non-wind and wind reasonably foreseeable future projects were initially considered for inclusion in the cumulative impact analysis. Non-wind projects involved transportation improvements, communications facilities, and power line improvements. Of these projects, only the Oregon Department of Transportation bridge replacement projects, now in progress along I-84, were considered close enough to the Project Area to be included in the cumulative impact analysis. The other transportation, communication, and power line improvement projects were considered to be too far from the Whistling Ridge Project Area to result in cumulative impacts and were therefore eliminated from further analysis. Reasonably foreseeable wind projects are shown in Figure 3.14-1. Of these wind projects, all except the Middle Mountain project were judged not likely visible from I-84. Nonetheless, the cumulative visual resource impact analysis does consider reasonably foreseeable wind projects with approximately the same geographic area as existing wind projects considered in that analysis. In addition, the cumulative impact analysis has been updated to reflect the discontinuation of the Middle Mountain project. The Middle Mountain project, originally proposed by Hood River County as a small community scale wind project of around 10 MW, would have been located on the south side of the Columbia River, approximately seventeen miles south of the Whistling Ridge Energy Project. However, on May 17, 2010, the Hood River County Commission decided to discontinue efforts to develop the Middle Mountain wind project and this project therefore has been removed from the cumulative impact analysis.
Figure 3.14-1
Existing and Proposed Development

Whistling Ridge Energy Project
Skamania County, Washington
In addition to the potential for cumulative visual impacts, two proposed projects in the project vicinity were identified as having a potential for other cumulative impacts with the Project.

**Middle Mountain Wind Project.** Hood River County is proposing this 9-MW project, which would be located approximately 10 miles south of Hood River. Six wind turbines are proposed in a single line on Middle Mountain. The project would be located approximately 15 miles south of the Project. The County has completed visual simulations, and a project informational meeting is scheduled for January 12, 2010. The County plans to continue its feasibility analysis in the coming months. Studies of impacts to biological resources have not been conducted.

A description of the Oregon Department of Transportation bridge replacement projects along I-84 are presented below:

**I-84 Bridge Replacements.** Oregon Department of Transportation is repairing or replacing 21 bridges on I-84 through the Columbia River Gorge with new bridges. Several of these projects are located near Hood River and these improvements are grouped as follows:

- **I-84 Cascade Locks to Hood River.** The bridges in this bundle span the junction of the Hood and Columbia rivers. Construction began in July 2008 and was completed in fall 2010.

- **I-84 Exit 64 (Hood River).** This bundle includes replacing the overpass bridge on Interstate 84 at exit 64 in Hood River and improving the interchange and Button Bridge Road beneath the overpass. Design work started in fall 2008 and would be completed by fall 2009. Construction is scheduled from early 2010 to late 2011.

- **I-84 Hood River to The Dalles.** These five bridges are located at the east end of the Columbia River Gorge. Construction on the Mosier Creek bridge replacement began in August 2008 and would be completed in fall 2010. Design work on the remaining bridges is complete and construction is scheduled from spring 2009 until early 2012. Repairs to the I-84 bridges at Hostetler Way in The Dalles and over Rock Creek in Mosier were completed in summer 2007.

---

3.14.3 CUMULATIVE IMPACTS

The following subsections describe the cumulative effects that the Proposed Action, in combination with the past, present, and reasonably foreseeable future actions identified above, would have on the various environmental resources discussed in this EIS. Cumulative impacts from the combination of these actions could occur for each of the environmental resources. However, the contribution of the Proposed Action to these cumulative impacts would vary, with the greatest contribution occurring in cumulative impacts on visual resources as constructing and operating the Project would add a view of an additional wind power project to travelers in the Gorge. In addition to the existing projects east of the Project Area, long-distance travelers in either direction along I-84 could see some elements of the Project, for approximately 12.5 miles traveling west and 6.5 miles traveling east. Travelers along SR 14 would not see the Proposed Action, which would be blocked by the bluff to the north of the road. As discussed in more depth below in Section 3.14.3.10, the visual impact of the Project along I-84 would be variable, with the number of turbine strings visible changing with topography. In many places only a few turbines would be visible, and the area where the most turbines would be visible (directly across the Columbia River from White Salmon and Bingen) would also be the area where the viewer would be the farthest from the Project Area (Figure 3.9-1). This would constitute a small cumulative impact when considered in combination with views of other wind projects located from 35 to 70 miles to the east.

Low levels of adverse cumulative impacts have been identified for energy and natural resources from the use of steel, concrete and vehicle fuel for construction, and for transportation (traffic safety and increased risk of accidents during construction periods of the Project and the I-84 bridge replacement projects, if they should overlap). Simultaneous construction projects may create a beneficial cumulative socioeconomic impact to local communities. Finally, by introducing up to 75 MW of clean renewable energy into the regional electrical grid, the Project would positively contribute to efforts to combat the cumulative impacts of climate change, and also contribute to efforts to improve air quality in the Columbia River Gorge vicinity.

All potential cumulative impacts are discussed below.

3.14.3.1 Earth

Past and present commercial logging of the site and surrounding area, agriculture, and construction of rural residences have resulted in cumulative impacts to geology and soils, primarily through increased erosion and soil disturbance and compaction. As the reasonably foreseeable future actions are developed, these actions likely would contribute to cumulative impacts. Reasonably foreseeable use of the Project Area for both the proposed the Project and for a continuation of commercial forestry could increase the potential for soil erosion, and contribute to these cumulative impacts for the life of the Project.

3.14.3.2 Air Quality

While past and present development and activities have resulted in some deterioration of air quality in the Project vicinity, the cumulative effect of these activities on air quality has been fairly negligible. Overall, the air quality in the region is considered good, as evidenced by
Oregon Department of Environmental Quality (ODEQ) reports on air quality for The Dalles, Oregon, the closest city with an air monitoring station. ODEQ reports air quality data using an air quality index based on particulate matter 2.5 micrometers diameter and smaller (PM$_{2.5}$). ODEQ’s 2008 report for The Dalles shows 339 days with good air quality, 25 days with moderate air quality, and no days with unhealthy air quality (ODEQ 2009).

While air quality in the Project Area is generally good, haze is a well-documented problem in the Columbia Gorge and the causes are being studied by the Southwest Clean Air Agency. In a 2008 Report, the agency found that haze was largely caused by winter stagnations that trap pollutants and fog (SWCAA 2008). In the summer, winds flow predominantly from the west, transporting emissions from the Portland metropolitan area into the Gorge. Wildfires also contribute to the haze when smoke is blown into the Gorge. There is no single source that is primarily responsible for haze; however, man-made sources are important contributors (ODEQ 2008). The most significant man-made sources contributing to haze in the Gorge include: power plant emissions; woodstoves; motor vehicles; non-road emissions (e.g. ships, trains, trucks); and agricultural sources of ammonia.

Construction of reasonably foreseeable future actions would be expected to generate dust and emissions during construction activities that could cumulatively contribute to air quality degradation. Construction of the terrestrial portions of the Proposed Action also would generate dust and emissions that likely would incrementally contribute, though slightly and only for a short time, to cumulative air quality impacts in the general Project vicinity.

**Climate Change.** Past and present actions in the Project vicinity, the region and across the globe have contributed to climate change and global warming. The past and present actions include, without limitation, the post-settlement conversion of native landscapes to residential, commercial and forestry uses, the introduction of carbon dioxide and other greenhouse gases from fossil fuel emission sources, particularly from automobiles and fossil fuel electrical generation sources, and in general, post-industrial manufacturing processes and land uses. Locally, residential, agricultural and commercial development is expected to continue a trend that permanently removes forests and replaces them with land uses that contribute to climate change.

“Climate change” refers to changes in the Earth’s global climate, including the rise in average surface temperature known as global warming. At this time, while there is nearly complete scientific consensus concerning the anthropogenic causes of global climate change, and also consensus on its deleterious impacts on the natural and human environment, there is uncertainty regarding the specific, localized effects of projected global warming upon regional temperature, precipitation and ocean conditions. The Federal Environmental Protection Agency (EPA) recently acknowledged that due to its impacts on climate change and related human health effects, carbon dioxide is considered an air quality pollutant requiring a regulatory response.35

35 In December, 2009, Environmental Protection Agency (EPA) Administrator Lisa Jackson announced that the agency had finalized its finding that greenhouse gases, including carbon dioxide, pose a threat to human health and welfare. The ruling allows the EPA to begin regulating greenhouse-gas emissions from power plants, factories and major industrial polluters, although the precise details of that regulation
The effects of global warming on the overall hydrology of the Columbia River Basin are difficult to separate from the natural variability resulting from cycles such as El Niño and the Pacific Decadal Oscillation. Further, forecasted changes to water supply or runoff volumes for the key Columbia River Basin drainages are more susceptible to shorter climatic cycles, such as El Niño and the Pacific Decadal Oscillation, than longer-term trends attributable to global warming. The variability seen in the Columbia River Basin over the last 80 years is greater than the variability experienced in the last 10–15 years. Therefore, even though the precise effects of global warming on the Columbia River Basin cannot be accurately determined at this time, estimated changes are within historic variations.

According to the US Global Change Research Program\(^{36}\), the predicted future climate change effects to the Pacific Northwest (PNW) are as follows:

*The climate model results selected for use in the National Assessment study (Hadley and Canadian) show regional warming continuing\(^{37}\) at an increased rate in the next century, in both summer and winter. Average warming over the region is projected to reach about +3°F by the 2020s and +5°F by the 2050s - well outside the natural range of climate in the 20th century. Annual precipitation changes projected through 2050 over the region range from a small decrease (-7%) to a slightly larger increase (+13%). The projected changes in precipitation, unlike the projected temperature changes, are within the range of year-to-year variability that has been experienced over the past 100 years in the PNW. The models suggest small changes in yearly average precipitation, but the seasonal trends are larger: nearly all the climate models show wetter winters and some show drier summers in the future.

*After 2050, the projected trend to a warmer, wetter regional climate continues with substantially more warming likely to occur in winter than in summer. By the 2090s, have yet to be worked out. "The threat is real," said Jackson. "If we don't act to reduce greenhouse-gas emissions, the planet we will leave to the future will be very different than the one we know today."

\(^{36}\) See: [US Global Change Research Program](http://www.usgcrp.gov/usgcrp/nacc/education/pnw/pnw-edu-2.htm)

\(^{37}\) A Note about General Circulation Models - This paper’s discussion about possible futures and their implications was taken from different sources based on a variety of general circulation models (GCMs) but is particularly based on the results of the Hadley Centre and Canadian Centre model simulations used by the National Assessment process. GCMs are tools used by scientists to construct plausible estimates of potential changes in climate. It is generally agreed that these models provide reasonable estimates of changes at the global and latitudinal scale.

However, for a variety of reasons, significant differences can exist on a regional scale between model outputs. Among these reasons are limits in the computational resources needed to resolve regional-scale topography and surface features. Because GCMs are coarse and do not accurately represent changes at the regional scale, caution should be used in interpreting the details of outputs from these models. However, until climate models that can resolve regional scales are available, these models offer the best “what if” scenarios available for consideration of vulnerabilities to climate change. The discussion describes plausible futures given our current understanding; however, these projections should not be considered definitive predictions of changes and effects.
Projected average summer temperatures rise by +7.3°F to 8.3°F, while winter temperatures rise +8.5°F to 10.6°F. Projected precipitation increases over the region range from 0 to 50% depending on the model. Warmer temperatures, though, mean less winter precipitation will fall as snow and therefore there will be less snowpack for later melting and use.

These projected changes are associated with large-scale shifts in atmospheric circulation over the Pacific, especially in winter, which resemble the changes that occur during the strongest El Niño events. As a result, winters are warmer and wetter -- both in total precipitation and in the amount of rainfall in heavy storms -- because warmer temperatures increase the quantity of water vapor.

Warming since 1900 in the Pacific Northwest ranges from 0 to 4°F. By 2100, both models project warming near 5°F west of the Cascades, with much larger warming further east in the Canadian model.

Precipitation has increased over most of the Pacific Northwest since 1900. Both climate models project continued precipitation increases, with the largest increases in the southern part of the region.

Although precise forecasting of the future effects of global warming on the Columbia River Basin may not be possible at this time, it is possible to consider how the development of the Project would affect emissions of greenhouse gases such as carbon dioxide. Reasonably foreseeable future actions, including continued use of fossil-fuel-burning automobiles, industrial processes, and electrical power generation are likely to continue, with cumulative impacts to air quality and acceleration of climate change through the continuing introduction of greenhouse gas emissions into the atmosphere. Power generated from wind displaces power generated by carbon dioxide emitting sources. In addition to wind energy generation being a non-emitting source, wind energy also is integrated into the hydropower system to reduce reliance on other thermal energy sources (i.e., coal, natural gas, or nuclear). Because the current mix of power sources in the Northwest relies heavily on thermal sources, electricity sourced from the wholesale market would likely have a significant greenhouse gas component, with attendant deleterious cumulative impacts. Integrating power generated by wind turbines into the hydropower system reduces reliance on other energy alternatives and avoids the need to procure 75 MW of electric power with a significant greenhouse gas component. Consequently, the Proposed Action would have a positive cumulative impact on efforts to combat air quality deterioration and climate change.

3.14.3.3 Water Resources

Creeks and Streams

Past and present development and activities have cumulatively caused various adverse impacts to creeks and streams in the general Project vicinity. Portions of some of these water bodies have been channelized or filled. Others have been affected by pollutants from stormwater runoff, wastewater discharges, and other sources. Reasonably foreseeable future actions, including continued commercial forestry practices and the additional development of rural residences could also contribute to these cumulative impacts.
Roadway construction and maintenance in the Project Area and vicinity could increase stormwater runoff, and increase sedimentation and turbidity if construction equipment crosses drainage ways. The Proposed Action would incrementally contribute to adverse cumulative impacts to creeks and streams in the general Project vicinity. In particular, the Proposed Action would potentially add to cumulative impacts to Little Buck Creek on the east side of the Project and possibly to Lapham Creek near the proposed site of the Operations and Maintenance Facility during Project construction from construction site stormwater runoff that would result in temporarily increased sedimentation and turbidity. The Proposed Action and other cumulative projects also would have a longer-term adverse cumulative impact to these creeks through the addition of increased impervious areas, which would increase the amount of stormwater runoff to these creeks, however the increase in impervious surfaces for the Proposed Action are expected to be minimal and largely limited to the wind turbine foundations and the Operations and Maintenance building. Lapham Creek drains into the Little White Salmon River, which drains into the Columbia River. Implementation of stormwater detention and other stormwater management practices for the Proposed Action would serve to minimize and possibly avoid Project contributions to these cumulative impacts, including contributions to cumulative impacts to other water bodies in the area, such as the Columbia River.

**Groundwater Resources**

Cumulative impacts to groundwater from past and present development and activities in the general Project vicinity have included groundwater withdrawals for wells. The reasonably foreseeable future actions would cumulatively affect groundwater for additional wells, including the proposed groundwater use of up to 5,000 gallons per day for the Operations and Maintenance Facility. The Proposed Action could contribute to the cumulative effect of potential groundwater contamination; however the potential for spills or contamination would be no larger than existing commercial forestry or agricultural operations.

### 3.14.3.4 Vegetation and Wetlands

#### Vegetation and Habitat

Past and present land development, timber harvest, and agricultural uses have resulted in a cumulatively significant change in the composition of vegetation and habitat types in the Project vicinity. In general, land development and agricultural uses have resulted in conversion of forested areas to non-forested areas, and timber harvests have resulted in a mosaic of forest ages, with average stand age declining over time from relatively short stand rotations. Changes in stand structure and complexity, patch size, and species distribution also have occurred. Few large, old-growth conifers or late-successional stands exist in the general Project vicinity. Accordingly, past and present uses have resulted in cumulative habitat conversion and an ongoing pattern of habitat fragmentation. Reasonably foreseeable future actions, such as ongoing land development and timber harvests, would continue this trend.

Project construction would take place in the context of the existing use of the Project vicinity generally for commercial forestry, which includes regular cycles of clearcutting and reforestation. Nonetheless, by removing trees and other vegetation in the wind Project area for
the life of the Project, development of the Proposed Action would contribute incrementally, though in a relatively minor way, to these cumulative impacts.

**Special-Status Plant Species**

Plant species listed as threatened or endangered and other special-status plant species have been cumulatively affected by past and present development and activities through habitat loss and direct effects to individual species. This trend would likely continue as future development occurs in areas where these species are present. However, the Proposed Action would not contribute to this adverse cumulative impact because, as described in Section 3.4.1.4, the Proposed Action would not affect any threatened or endangered or other special-status plant species.

**Wetlands**

Incremental losses and degradation of wetlands over time have cumulatively depleted wetland resources in the United States. In the Project vicinity, wetlands likely were previously impacted by construction of a variety of activities, including development of roads and railroads, agricultural activities, and past timber harvests. Reasonably foreseeable future actions may also affect wetlands in the Project vicinity, but it is expected that these future projects would be required to avoid, minimize, and compensate for any potential impacts to wetlands from filling or other activities as part of Project Section 404 permitting requirements. Regardless, because construction and operation of the proposed Project would not impact wetlands, implementation of the Proposed Action would not contribute to cumulative impacts to wetlands.

**Noxious Weeds**

Past and present activities in the Project vicinity have led to a cumulatively significant spread of noxious weeds in the vicinity, and noxious weed spread could continue with reasonably foreseeable future actions. Although mitigation measures have been identified to minimize the spread of noxious weeds by the Proposed Action, it is likely that noxious weed impacts would nonetheless still occur under the Proposed Action. The Proposed Action thus would contribute incrementally, though in a relatively minor way, to this cumulative impact.

3.14.3.5 Habitat and Wildlife

**Terrestrial Wildlife Species**

Past and present development and other activities have had a cumulative adverse impact on terrestrial wildlife species and their habitat in the general Project vicinity. The clearing and conversion of land for home sites, utility infrastructure, and other uses since approximately the 19th century has resulted in the cumulative loss of wildlife habitat. Wildlife habitat also has been cumulatively modified through activities such as logging and other silvicultural activities, which have altered and fragmented habitat. This habitat loss and modification has resulted in the displacement of wildlife species. While these changes to existing habitat have been cumulatively detrimental to some species of wildlife, some changes that have resulted in conversion from one habitat type to another (as opposed to conversion to human uses) have been cumulatively
beneficial to other wildlife species. Wildlife species also have been directly affected by hunting and trapping activities, as well as incidental harm and killing from other human activities in the area. Reasonably foreseeable future actions involving highway improvements, residential, commercial, agricultural and other development and logging would be expected to incrementally add to these cumulative impacts.

The Proposed Action would impact terrestrial wildlife habitat through permanent improvement of approximately 56 acres now in grass/forb, field/shrub, managed coniferous or mixed deciduous-coniferous forest from within the Project Area (See Table 1-3 and Section 3.3). Some terrestrial wildlife species may also be disturbed by Project construction activities or avoid the Project Area temporarily during construction. The Proposed Action thus would contribute incrementally, though in a relatively minor way, to the cumulative impact on terrestrial wildlife species and their habitat.

**Bird and Bat Species**

Past and present development and other activities have had a cumulative adverse impact on wildlife species, including birds and bats, with permanent alteration and loss of their habitat in the general Project vicinity. The clearing and conversion of land for home sites, utility infrastructure, and other uses since approximately the 19th century has resulted in the cumulative loss of habitat for birds and bats. Habitat for birds and bats has also been cumulatively modified through activities such as logging and other silvicultural activities, which have altered and fragmented habitat. This habitat loss and modification has resulted in the displacement and mortality of these wildlife species. Further, as discussed below, past and present residential and other development has a continuing impact on these species, through building, window, transmission line and telecommunication facility strikes, vehicular strikes, and the predation of these species by domestic cats. Reasonably foreseeable future actions, including non-wind energy generation uses, are expected to have a continuing negative impact on these species.

As documented elsewhere in this DEIS in Section 3.4 Biology, the Proposed Action would impact bird and bat species. Because of the variability in species, habitat, and flight patterns on a regional basis, it is difficult to assess potential cumulative impacts of “full build-out” development of wind power on birds and bats over a large geographic area. However, the National Academy of Sciences National Research Council estimated the best and worse case fatality estimates for birds and bats based on a regional “full-build” scenario in 2020 for the Mid-Atlantic Highlands (NRC 2007). This study is considered the most thorough, objective and “best available science” on the topic of cumulative impacts from wind energy projects, and made use of a real world example (although from a different region of the country from Whistling Ridge). This study concluded that it is unlikely that the predicted level of fatalities would result in measurable impacts to migratory populations of most species, although for rare and local populations, the cumulative impacts when combined with all other man-made sources of mortality could affect population viability.

The reference in this study to “all other man-made sources of mortality” in the National Research Council study highlights one of the numerous caveats and difficulties inherent to such a study: collisions with turbines are only one element of man-made cumulative effects on bird and bat populations in a given region. Examples of other man-made impacts include collisions with
buildings, transmission lines and vehicles, habitat loss, and predation by domestic cats. Erickson et. al. (2005) concluded that these sources of mortality are likely much larger than the potential impacts of wind power development. Other uncertainties included:

- While estimation of bird fatalities caused by wind energy projects is possible, data on bat fatalities is currently sparse, and typically is not species-specific.

- Estimates of turbine fatalities from past projects, especially those from the 1980s through the 1990s, are based on a variety of methodologies and do not include corrections for observer bias and potential removal of carcasses by scavengers.

- Factors such as the turbine height and design, rotor velocity, number and dispersion of turbines, location of turbines in the landscape, and operational schedule of turbines may influence fatalities. Turbine technology is continually changing and it cannot be predicted what technology will be available in the future.

A similar cumulative impact study on avian and bats was performed by WEST, Inc. for the Klickitat County Planning Department in 2008 and updated in 2010 (WEST, Inc. 2010). WEST’s 2008 study reviewed 17 wind-energy facilities totaling 2,464 MW that were in operation in the CPE of Eastern Washington and Oregon, and an additional 30 potential wind-energy facilities that were planned or being constructed within the CPE as of mid-2008. At the time of their 2008 study, WEST found that there was approximately 6,665 MW of existing or proposed wind-energy facilities in the CPE. For the purpose of their analysis, WEST assumed that 6,700 MW of wind power would be present in the CPE. However, past experience indicates that not all permitted projects are built, so these figures likely overestimate what would actually be constructed. Klickitat County added this study to the Klickitat County energy Overlay Zone Environmental Impact Statement originally issued in September 2004. The 2010 study is included in this EIS as Appendix C-11.  

Like the National Research Council study, for the purpose of their cumulative analysis, WEST assumed that for cumulative impacts to occur, there must be a potential for a long-term reduction in the size of a population of birds or bats.

WEST’s general approach to the cumulative effects analysis was to summarize results of fatality monitoring studies at operational wind-energy facilities within the CPE, and then use those results to estimate impacts for all constructed and proposed wind-energy facilities within the same ecoregion. At the time of the WEST study, most wind energy development in northern Oregon and southern Washington had been within an area historically characterized by open, arid shrub-steppe and grassland-steppe habitats. WEST found that the current predominant land use of the CPE is dryland agriculture and rangeland, with low precipitation (6 to 12 inches per year). Habitat and land use throughout the entire CPE are similar.

38 A similar, but somewhat more limited cumulative impact study was prepared for the Shepherd’s Flat Wind Energy Facility in 2007. (Included in this EIS as Appendix C-12)
WEST’s cumulative effects analysis relies heavily on data from 12 wind-energy facilities in the CPE where fatality monitoring has occurred. Most of the operating facilities have had or would have some sort of avian and bat post-construction casualty monitoring associated with them, and post-construction fatality monitoring data are available from 12 operational wind energy facilities in the CPE. For each of the individual study areas from which fatality results are available, the predominant land use was a mosaic of agriculture (mainly dryland wheat farming) and grassland or shrub-steppe rangeland used for livestock grazing.

West estimated the population losses for birds (excluding raptors), raptors, upland game birds, waterfowl, waterbirds, and shorebirds, passerines, sensitive bird species, and bats. Their study estimated 67.1–69.5 percent of losses would be to passerines, of which horned lark fatalities made up nearly half. Fatalities to other avian and bat populations were estimated to be substantially less. None of the estimated fatalities were anticipated to cause a significant loss in population, and no cumulative impacts were anticipated.

In comparison to the CPE, the site proposed for the Project is in a different ecoregion, (the Eastern Cascades ecoregion,) which to date has not experienced any wind energy development. In addition, the Project Area is more mountainous, receives more precipitation (an average of 84.06 inches per year as measured at the Skamania fish Hatchery), and is more forested than the CPE. Due to the difference in habitat types between the Project Area and the CPE, the results of the direct impact analysis for the Project cannot be directly applied to the results of WEST’s cumulative effects analysis for the CPE. However, WEST’s cumulative effects analysis is relevant in considering the added impacts of the Proposed Action to the overall cumulative biological impacts of all wind energy projects in the region.

As described in Section 3.4 Biological Resources, operation of the Project would result in unavoidable mortality to birds and bats through turbine collisions, but there likely would not be enough mortality to negatively affect the population viability of any single species.

The Eastern Cascades Ecoregion likely contains bird and bat populations that are separate from those populations in the CPE due to the significant differences in habitat. The potential for cumulative impacts to birds and bats associated with wind energy development in the Eastern Cascades, and indeed throughout the coniferous forested portions of all of western Washington and Oregon, is extremely small. No existing wind energy developments occur in the Eastern Cascades. With the exception of the Grayland project in Pacific County, a very small 4-turbine wind energy facility, there are no other existing wind energy facilities in forested habitats of western Washington or Oregon. To date, only three additional projects have been proposed in this entire area, including the Middle Mountain Project in Hood River County, Oregon, the Coyote Crest project in Pacific and Lewis Counties, Washington, and the Radar Ridge project in Pacific County, Washington. The only other project proposed in the Eastern Cascades, Middle Mountain, is no longer being pursued by Hood River County, as the County Commission decided to cease efforts to pursue this community scale project of around 10 MW at its meeting on May 17, 2010 (see http://www.co.hood-river.or.us).

The one existing project (Grayland) and remaining two projects (Coyote Crest, Radar Ridge) are all in extreme western Washington within another ecoregion, the Northwest Coast Ecoregion. It is not certain that Coyote Crest and Radar Ridge would both be constructed. As with
populations in the CPE, wind energy development in the Northwest Coast ecoregion would have little effect on separate bird and bat populations in the Eastern Cascades Ecoregion. In addition, based on preconstruction avian and bat studies conducted at these projects, both raptor and all bird use is generally lower than within the CPE (Table 3.14-1), indicating the potential for avian impacts is likely lower in forested ecoregions than within the CPE. Bat use is more varied, ranging from quite low to relatively high (Table 3.14-2). Again, however, based on the very few wind energy projects proposed in this region, these projects, taken together, would likely have a very small cumulative impact on birds and bat populations.

Operation of the Middle Mountain wind project also would presumably cause some mortality to birds and bats. Raptors, including bald eagles, golden eagles, northern goshawks and others could travel the 12 air miles between the two wind projects, and the two projects would be considered part of the same regional population of raptors. The Proposed Action thus would contribute incrementally, though in a relatively minor way, to the cumulative impact on bird and bat species in the region.

Finally, the evaluation of cumulative impacts for wind energy generation facilities should be considered in the context of other mortality threats to these species, which have been estimated in recent research as many times larger than those from wind energy generation (Erickson et al. 2005; 2008). Moreover, the cumulative impacts analysis for wind energy generation facilities does not account for potential mortality to birds and bats caused by climate change, and the beneficial biological impact of renewable energy in avoiding these impacts. For example, one study from 2009 estimated that, based on performance in the United States and Europe, wind facilities and nuclear power stations are responsible each for between 0.3 and 0.4 bird fatalities per gigawatt-hour (GWh) of electricity while fossil-fueled power stations are responsible for about 5.2 fatalities per GWh (Sovacool 2009).

**Fish Species**

Past and present development and other activities have had an adverse impact on fish species, including the alteration and loss of their habitat in the general Project vicinity. Negative impacts to fish and other aquatic resources from past and present, as well as reasonably foreseeable future development in the region include the alteration of streams and rivers by the introduction of hydroelectric generation dams, loss of riparian habitat, increased sediment loading, increased stream temperatures, pollution from herbicide and insecticide use, changes in peak and low stream flows, fragmentation of fish habitat, decreases in streambank stability, altered nutrient supply, and stormwater runoff from roads and bridges. The proposed work on the I-84 bridges may cause temporary increases in impacts from construction activities. These impacts are anticipated to continue into the foreseeable future.

Typically, wind energy generation projects in the region tend to be located in upland areas and generally well away from fish habitat, which is also true of the proposed Project. Therefore, wind energy projects in the region in general, and the proposed Project in particular, would not contribute to direct cumulative impacts to fish species.

Potential indirect cumulative impacts to fish species can occur through a somewhat complex relationship among wind projects interconnected to BPA transmission system, Columbia River hydro operations, and operation of this hydroelectric generation system to meet Clean Water Act (CWA) and ESA requirements for listed fish species. There are currently over 3,500 2,000 MW of wind energy connected to the transmission grid within BPA’s Balancing Area, and several thousand more MW of wind power are expected to be developed and connected to the grid in the next few years. The majority of these projects are concentrated in the geographic area east of the Columbia River Gorge, and the overall amount of wind power on BPA’s transmission system largely depends on wind velocities in this particular area. Accordingly, the amount of wind power on BPA’s system can fluctuate widely and relatively quickly, depending on whether wind

---

speeds in this area are low (meaning very little wind power is being generated in this area) or high (meaning wind projects in this area are generating close to or at full capacity).

Within BPA’s Balancing Area, there must be a match between generation and loads at all times. BPA has historically reserved capability in the hydroelectric system to provide balancing services for wind power output swings when needed. However, the increasingly large proportional share of wind power on BPA’s system and the natural fluctuation of this power have combined to result in large, unscheduled swings in wind generation of up to several hundred megawatts within a single hour that cannot be handled by reserved capability alone. In such situations, BPA must immediately decrease generation in the BPA Balancing Area to maintain the constant balance of generation and load needed to keep the system stable. Using the hydroelectric system to decrease generation in these situations is often not available because: (1) reservoir space at the hydro projects is being maintained for required flood protection (meaning that additional water cannot be stored); and/or (2) additional water cannot be spilled, rather than run through turbines, at the hydro projects due to CWA limits on the level of total dissolved gases in the river and potential impacts on ESA-listed fish species from higher levels of total dissolved gases.

For these reasons, BPA has been working with wind project developers and operators for the past few years to develop measures for temporarily reducing sources of wind generation within the BPA Balancing Area when necessary. As part of a comprehensive review of wind project interconnections and their effects that was conducted in winter 2008, BPA established transmission operation protocols under which BPA’s dispatch system automatically instructs wind project operators to reduce their generation to specified levels if necessary for reliability and ESA or CWA compliance. BPA has issued Dispatcher Standing Order (DSO) 216 to document these protocols, and is continuing to refine and clarify this DSO as more is learned about wind project operations relative to BPA’s transmission system (visit http://www.transmission.bpa.gov/wind/op_controls/default.cfm for more information). More recently, BPA has adopted an interim Environmental Redispatch policy, under which BPA would temporarily limit the energy output of regional generators, including wind generation, only as a last resort to avoid harm to salmon and steelhead and assure reliable energy delivery during unusually high seasonal river flows (see BPA’s Interim Environmental Redispatch and Negative Pricing Policies, Administrator’s Final Record of Decision, May 2011, available at http://www.bpa.gov/corporate/pubs/RODS/2011/ERandNegativePricing_FinalROD_web.pdf).

During an Environmental Redispatch, utilities and consumers who purchase wind power or other energy would continue to receive the full energy deliveries associated with their transmission schedules, but the energy would originate from the FCRPS instead of other resources. These measures ensure that wind power on BPA’s transmission system does not cumulatively impact Columbia River hydro operations necessary for listed fish species.

The proposed Project would be subject to DSO 216 and BPA’s interim Environmental Redispatch policy, which would avoid any contribution from the proposed Project to indirect cumulative impacts to fish species. In addition, because the proposed Project is located at the west end of the Columbia River Gorge rather than the east end (i.e., approximately 60 miles to the west of the Columbia Plateau wind generation vicinity), wind patterns in the Project vicinity
can vary significantly at any given point in time from those in the area where the majority of existing and proposed wind projects are located. This difference adds diversity in wind energy production and further reduces the potential for any contribution of the proposed Project to indirect cumulative impacts to fish species during periods of time when generation needs to be decreased to maintain transmission system stability. The added diversity should assist BPA in implementing regulation requirements on the hydro system. Overall, the proposed Project would not be expected to contribute, either directly or indirectly, to cumulative impacts to fish species.

3.14.3.6 Energy and Natural Resources

Past and present land development, timber harvest, and agricultural uses have resulted in a cumulative use of energy and depletion of energy resources in the Project vicinity. The Project would have a positive effect on energy, in that it would produce more energy than that used to build and operate the facility. The Project would consume a limited amount of natural resources for construction, including steel, concrete, and fuel for machinery. The amount of these resources used would be insignificant compared to available supply. The Middle Mountain wind project would be similar in the balance between consumption of energy and generation of renewable energy to the Project although both the energy payback and the amount of resources consumed would be smaller, since the Middle Mountain project would have only six turbines, and is anticipated at 9 MW to be approximately 12 percent of the size of the Project. The I-84 bridge improvements would consume steel, concrete and fuel. The combined consumption of these natural resources is small compared to available supply. The Proposed Action thus would contribute incrementally, though in a relatively minor way, to the cumulative impact on use of natural resources in the region.

3.14.3.7 Public Health and Safety

Past development of high voltage transmission lines across the Project Area has created a low level of EMF exposure. The Project would include 34.5-kV collector lines and systems, primarily located underground. There would be a new substation located adjacent to BPA’s existing North Bonneville to Midway 230-kV transmission line, and a new interconnection from the substation to the 230-kV transmission line. Adding additional overhead and underground cables would cumulatively increase the overall level of EMF exposure. The electric and magnetic fields generated by the collector lines and underground systems under the Proposed Action, which are described in Section 3.6, Public Environmental Health and Safety, would contribute to the cumulative levels of EMF in the Project vicinity, though only slightly because of cable shielding and undergrounding, the minor nature of these Project elements, and the distance to existing residences.

During construction of the Project, there would be a slight increase in risk of traffic or worker accidents during the construction period. This impact would take place in the background of existing land use patterns based on commercial forestry, agriculture, and residential development. Effects of construction of the Middle Mountain wind project and I-84 bridge replacements would most likely be similar, though the impact of the Middle Mountain project would be smaller, given the smaller size of the project. Given the anticipated low number of incidents and the available capacity of the local emergency responders and hospitals to respond
to those incidents, the cumulative impact would be relatively minor, and would be reduced once construction is completed.

### 3.14.3.8 Noise

Past and present development activities have introduced noise sources to the vicinity, including residential construction and development, commercial forestry operations, motor vehicles, machinery and domestic livestock and pets. Implementation of the cumulative actions identified in Sections 3.14.1 and 3.14.2 would be expected to generate various levels of noise through the Project vicinity, as would the Proposed Action. Depending on the proximity and timing of these actions, there could be cumulative noise impacts if actions are undertaken simultaneously and in relative close relation to each other. For most of the cumulative actions, it is expected that they would not result in cumulative noise impacts due to temporal or spatial separation. However, given the expected timing of the I-84 bridge improvement projects in the vicinity of the proposed Project, it is possible, however not expected, that receptors in the area could be exposed to cumulative noise impacts during the construction of these roadway projects in combination with the Proposed Action.

Operation of the Proposed Action would result in elevated noise levels from the movement of the turbines, maintenance activities, and operation related traffic. The operation noise levels would vary with the speed of the turbines. While the noise levels are not predicted to exceed regulated noise levels, the Proposed Action would contribute in minor ways to cumulative increases in noise levels in the Project vicinity. These contributions would be lessened through the application of mitigation measures described in Section 3.7 Noise.

### 3.14.3.9 Land Use and Recreation

The cumulative past, present and reasonably foreseeable actions identified in Sections 3.14.1 and 3.14.2 have resulted in changes to land use and would be expected to continue the incremental growth of developed land uses in the Project vicinity. The Proposed Action would be consistent with existing land use planning and zoning designations for Project facilities, and would not result in any inconsistencies with existing or planned adjacent land uses. The Proposed Action also would have little or no effect on existing land use patterns. The land use impact of the Middle Mountain wind project has not been studied but is unlikely to be inconsistent with local land use codes, to cause changes to local land use patterns, or to create cumulative impacts.

The Project would have little to no impact on recreation resources, and this is most likely the case for the Middle Mountain wind project as well. The I-84 bridge replacements may have a beneficial impact to recreation users, as roadway improvements may improve access to recreational resources in the area. Given the abundant recreational resources in the area and the low level of impacts, the Proposed Action’s contribution to cumulative impacts to recreation would be minor.

### 3.14.3.10 Visual Resources

While parts of the Gifford Pinchot National Forest near the Project Area remain undeveloped, past and present development activities have changed the visual landscape in the immediate
Project vicinity by introducing manmade features and altering natural forms. These uses include residential, commercial and agricultural development, the construction of highways, bridges and roads, electrical transmission towers and hydroelectric dams, and telecommunication facilities. Ongoing human activities in the vicinity also contribute to continuing cumulative visual impacts, primarily views of clear-cutting and agricultural openings in natural vegetation patterns. Except for private timber operations, private development activity in the Project vicinity would be subject to the visual impact limitations placed on private development by the CRGNSA. Future private development would either be required to not be visually evident or be visually subordinate. Reasonably foreseeable future actions would be expected to continue current trends, as the past and present patterns of land use are expected to continue.

During construction, the Project would contribute to cumulative visual impacts through visible construction activities, although some viewers interested in viewing Project construction may consider the Project’s contribution to be a positive impact. After construction is complete, the presence of the proposed wind turbines would contribute to cumulative visual impacts on nearby residents and motorists passing by on county roads, SR 14 and I-84.

The visual impacts of the Project would not be higher than low to moderate at any of the viewpoints examined. In considering the two specific reasonably foreseeable future projects, Hood River County estimated that the proposed Middle Mountain project would be visible as far away as 9.32 miles from that project. The two projects are approximately 12 air miles apart, and there may therefore be a few locations where both projects would be visible, though these would be background views at the limit of visibility. The visual impact of the I-84 bridge improvements would be limited to the period of construction. Oregon Department of Transportation states that “New bridge designs will complement the aesthetic appeal of the Gorge and reflect the allure of the adjacent Historic Columbia River Highway.” Thus, these new bridges may result in a positive impact to visual resources. Therefore, the visual impacts of the Project would not be higher than low to moderate at any of the viewpoints examined.

Past and present development of wind energy projects has also taken place at other locations in the Columbia River Gorge. The visual effect of these projects on the regional landscape and the experience of viewers is also a consideration, since long-distance drivers passing through the Gorge would recall seeing wind energy development in the Columbia Gorge. To assess this impact, the visibility of ten existing wind projects east of the Project Area were modeled in the draft EIS for cumulative impacts using the following assumptions:

- Visibility was modeled to 20 miles. This distance is considered very conservative and was chosen to accommodate recreation users with binoculars.

- Visibility was modeled using bare-earth surfaces without vegetation. In reality, many views would be blocked by trees, particularly in the Project vicinity.

---

40 See: http://www.co.hood-river.or.us/vertical/Sites/%7B4BB5BFDA-3709-449E-9B16-B62A0A0DDE4%7D/uploads/%7B7909769CE-99F0-47B5-9CAE-77015BF9D737%7D.PDF.

41 See: http://www.oregon.gov/ODOT/HWY/REGION1/ColumbiaGorge/.
Visibility was modeled from single points representing the approximate location of each project taken from the Northwest Power and Conservation Council’s on-line Northwest Power Generation Map. This visibility analysis documents visibility of even single elements of wind energy facilities, such as distant and fleeting views of wind energy nacelles and/or turbine blade tips, and does not differentiate these sightings from a more prominent view of entire turbines or generation facilities. The visibility analysis also does not account for the overall visual or aesthetic context of landscapes that are not in a pristine condition, most particularly the presence of existing electrical transmission lines which dominate the viewscape in many areas analyzed. Overall, these assumptions almost certainly represent a significant overstatement of the visibility of these facilities, and their cumulative impacts to the landscape.

Following publication of the draft EIS, eight additional wind projects were identified within a distance of approximately 70 miles east of the Whistling Ridge Energy Project Area. These projects have been added to the visual quality analysis but have not been modeled for the EIS. In addition, reasonably foreseeable future wind projects have been added to the analysis. Nevertheless, the visual impacts of the additional existing and reasonably foreseeable wind projects would be similar to the impacts of the 10 projects originally modeled in the draft EIS. Thus, for a motorist driving east on I-84, the first of the wind energy projects would become visible near Wishram, approximately 35 miles to the east of the Project Area. From this point eastward, wind projects are potentially visible (using the assumptions stated) for approximately 52 of the following 64 miles (Figure 3.14-2).

Construction of the Project would add some additional views of wind turbines in addition to the past, present, and reasonably foreseeable wind power development projects and existing electrical transmission facilities. Travelers on I-84 through the Gorge would be able to see the Project for a time while traveling near Hood River. Travelers along I-84 could each see at least some part or elements of the Project, for approximately 12.5 miles traveling west and 6.5 miles traveling east. At normal highway speeds this would result in an additional visual impact for between 7 and 12 minutes. Travelers along SR 14 would not see the Proposed Action, which would be blocked by the bluff to the north of the road.

The visual impact of the Project along I-84 would be variable, with the number of turbine strings and turbine equipment elements visible changing with topography. In many places only a few turbines would be visible, and the area where the most turbines would be visible (directly across

---

42 See: http://www.nwcouncil.org/maps/power/Default.asp

43 The project area is within view for approximately 17 miles, however in each direction the curvature of the road and the location of the project mean that the project would be behind drivers and passengers for some of that distance.
the Columbia River from White Salmon and Bingen) would also be the area where the viewer would be the farthest from the Project Area (See Figure 3.9-1).

The maximum impact of the Project along I-84 can be pictured by referring to Figures 3.9-10 (Viewpoint 13) or 3.9-8 (Viewpoint 11), which show viewpoints located on I-84. From Viewpoint 11, for instance, a traveler proceeding west would see a maximum of 25 turbine hubs and 70 blade tips, all at a distance of 14 kilometers (8.9 miles), or far background distance. From Viewpoint 13, a traveler proceeding east would see a maximum of 12 turbine hubs and 25 blade tips, at a distance of around 5.5 kilometers (3.4 miles) or middle-ground distance. As discussed in Section 3.9, however, these numbers overstate the visual impact, for the following reasons:

- The number of hubs and blade tips visible is calculated using bare-earth surface models. In reality, views of many turbines would be blocked by trees.
- All turbine blades would not be visible when the blades are rotating.
- Atmospheric haze, when present, would reduce the visibility of the turbines, especially at background distances.

For westbound travelers, the Project would be the last wind power project visible, and for eastbound travelers it would be the first. Building the Project would therefore add a small cumulative visual impact for long-distance travelers.

A similar cumulative impact could occur, probably on a more consistent basis, for residents of and frequent visitors to the local area. While residents of White Salmon, for example, might not see turbines from Whistling Ridge and Middle Mountain on a daily basis, they would likely experience repetitive views of wind turbines (or portions of wind turbines) through their local travels over a period of weeks, months or years. The “significance” of these perceptions would be individual in nature and inherently subjective, and is considered in the context of an altered landscape that includes hydroelectric generation facilities, transmission towers and lines, roads, bridges, highways and other land uses. Consequently, some local residents and frequent visitors might perceive what they individually consider to be a substantial change to the overall character of the local landscape. Although the geographical and topographical setting of the Project (including north-south trending ridge lines) limits its regional visibility, such a response would be more likely with the development of multiple wind projects.
Figure 3.14-2
Existing Wind Projects Visibility from I-84
3.14.3.11 Historical and Cultural Resources

Cultural and historic resources in the Project vicinity have been and are being affected because of past, present, and current development and activities. These cumulative impacts include the redevelopment of land used for pioneer settlements, such as the Underwood town site north of the Project Area, and natural degradation of wooden flumes that were used in the late 1800s and early 1900s to transport logs to the Columbia River. Although the Proposed Action would not affect any known upland archaeological or historic resources, there is the potential for the Proposed Action to impact previously undiscovered cultural resources or artifacts. Mitigation measures are identified in Section 3.10, Historic and Cultural Resources, to lessen or avoid the potential for this impact. However, if the Proposed Action does impact previously undiscovered cultural resources or artifacts, it would contribute incrementally to the adverse cumulative impact to cultural resources in the area.

3.14.3.12 Transportation

The cumulative actions identified in Sections 3.14.1 and 3.14.2 have resulted in increases in traffic and would be expected to continue the incremental growth of traffic in the Project vicinity. The Proposed Action would contribute to cumulative traffic levels in the Project vicinity, but generally only during the construction phase of the Proposed Action. Construction of the Project is scheduled for a one-year period beginning in 2011. Construction of the I-84 bridges would take place in 2009, 2010 and 2011, with the majority of construction taking place in 2010. There could be some potential cumulative traffic congestion for travelers along I-84 during periods when both construction projects were active. However, workers traveling to the Whistling Ridge site could use SR 14 as an alternative route.

3.14.3.13 Public Services and Utilities

Past and present development and activities have resulted in an incremental increase in demand for public services and utilities. The Proposed Action would not be expected to adversely affect the overall capacity or ability to serve of any utility in the area, and thus would not contribute to cumulative impacts to utilities. By providing a potential backup or alternative power source for the Skamania County Public Utility District (PUD), the Proposed Action may contribute to a positive impact on utilities.

Construction of the Project, and the use of construction workers from outside the immediate area, could result in a minor and temporary increase in the demand for public services including police departments, providers of emergency medical services, and local fire departments, and would contribute to a cumulative increase in demand when added to the construction of the Middle Mountain wind project and I-84 bridge improvement projects. The temporary increased demand

44 See:
for services during the construction period caused by the average of 143 workers (265 during the peak month) would be substantially reduced during operation for the permanent workforce of nine full-time workers.

3.14.3.14 Socioeconomics

During construction, the Proposed Action would contribute incrementally to a positive cumulative impact on the economy of the local community by providing additional employment and increased need for goods and services. While the Proposed Action and other cumulative actions would increase the number of construction workers in the Project vicinity, there appears to be sufficient vacant rental dwellings and available temporary housing, hotel/motel, camping, and RV units in the general Project vicinity to accommodate the potentially overlapping construction schedules of the Proposed Action and some of the possibly concurrent cumulative actions such as the construction of the Middle Mountain wind project and the I-84 bridge improvement project.

During operation, the Proposed Action would employ nine full-time workers. The operational workforce would have a minor cumulative effect on population, employment, and housing in the Project vicinity. The fiscal impact of the Project would be highly positive, as the Project’s assessed value of up to $87.5 million would generate approximately $800,000 per year in tax distributions to municipal, county, and other local jurisdictions. Operation of the Proposed Action would be expected to have a major contribution to cumulative financial benefits to Klickitat and Skamania counties.

3.14.4 REFERENCES

3.15 RELATIONSHIP BETWEEN SHORT-TERM USES OF THE ENVIRONMENT AND LONG-TERM PRODUCTIVITY

The Proposed Action under consideration does not pose short-term impacts that would significantly alter the long-term productivity of the affected environment. The turbines and associated facilities would take less than 5 percent of the arable land in the 1,152-acre study area out of production, and the remainder of the land could still be used for commercial forestry. After decommissioning of the Project, all of the land could revert to its previous uses. Little change in the long-term environmental productivity of the land would have been caused.

3.16 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

Irreversible commitments of resources occur when a non-renewable resource such as minerals or petroleum-based fuels is used for the construction or operation of a Proposed Action. An irretrievable commitment of resources occurs when a federal agency gives up all rights or protections for a particular resource that it has ownership of or jurisdiction over, whether it be land, trees, water, animal or plant species, or some other resource.

The Proposed Action would include the use of steel, gravel, wood, and other non-renewable material to construct the wind turbines, access roads, electrical power line, operations and maintenance facilities, and substations. Materials would come from outside sources or from local borrow pits. Petroleum-based fuels for vehicles and equipment would also be required. Development of the proposed action would result in the irretrievable commitment of a small amount of commercial forestry land. These commitments are irretrievable rather than irreversible because the Project could be decommissioned in the future and previous land uses
restored. In addition, many materials used to construct and operate the Project could be recycled upon decommissioning.

3.17 INTENTIONAL DESTRUCTIVE ACTS

BPA, like other utilities and government agencies, experiences incidents of criminal activity such as vandalism, theft and burglary. Some of these incidents cause significant operational and financial impacts to the agency. Between 2007 and 2009, BPA experienced approximately 128 incidents of burglary, theft and vandalism. These incidents cost the agency approximately $1,624,110. The BPA Security and Emergency Response Office works closely with Federal Law Enforcement Agencies and, local and state police to ensure all incidents are appropriately reported, investigated and prosecuted. This effort has resulted in the return of BPA property and in court ordered restitution to be paid by the convicted parties.

Issues concerning international terrorist activity, domestic terrorism and sabotage remain a significant concern for BPA and other critical infrastructure operators. BPA maintains close liaison with Federal Law Enforcement Agencies, Department of Homeland Security, and Local jurisdictions to ensure effective communication of information and intelligence.

The impacts from vandalism and theft, though expensive, do not generally cause a disruption of service to the area. Stealing equipment from electrical substations, however, can be extremely dangerous. In fact, nationwide, many would-be thieves have been electrocuted while attempting to steal equipment from energized facilities. On Oct. 11, 2006, a man in La Center, Washington, was electrocuted while apparently attempting to steal copper from an electrical substation.

Federal and other utilities use physical deterrents such as fencing, cameras, and warning signs to help prevent theft, vandalism and unauthorized access to facilities. In addition, through its Crime Witness Program, BPA offers up to $25,000 for information that leads to the arrest and conviction of individuals committing crimes against BPA facilities. Anyone having such information can call BPA’s Crime Witness Hotline at (800) 437-2744. The line is confidential, and rewards are issued in such a way that the caller’s identity remains confidential.

Acts of sabotage or terrorism on electrical facilities in the Pacific Northwest are rare, though some have occurred. These acts generally focused on attempts to destroy large transmission line steel towers. For example, in 1999, a large transmission line steel tower in Bend, Oregon was toppled.

Depending on the size and voltage of the line, destroying towers or other equipment could cause electrical service to be disrupted to utility customers and end users. The effects of these acts would be as varied as those from the occasional sudden storm, accident or blackout and would depend on the particular configuration of the transmission system in the area. While in some situations these acts would have no noticeable effect on electrical service, in other situations, service could be disrupted in the local area, or if the damaged equipment was part of the main transmission system, a much larger area could be left without power.
When a loss of electricity occurs, all services provided by electrical energy cease. Illumination is lost. Lighting used by residential, commercial, industrial and municipal customers for safe movement and security is affected. Residential consumers lose heat. Electricity for cooking and refrigeration is also lost, so residential, commercial, and industrial customers cannot prepare or preserve food and perishables. Residential, commercial, and industrial customers experience comfort/safety and temperature impacts, increases in smoke and pollen, and changes in humidity, due to loss of ventilation. Mechanical drives stop, causing impacts as elevators, food preparation machines, and appliances for cleaning, hygiene, and grooming are unavailable to residential customers. Commercial and industrial customers also lose service for elevators, food preparation, cleaning, office equipment, heavy equipment, and fuel pumps.

In addition, roadways experience gridlock where traffic signals fail to operate. Mass transit that depends on electricity, such as light rail systems, can be impacted. Sewage transportation and treatment can be disrupted.

A special problem is the loss of industrial continuous process heat. Electricity loss also affects alarm systems, communication systems, cash registers, and equipment for fire and police departments. Loss of power to hospitals and people on life-support systems can be life-threatening.

Overhead transmission conductors and the structures that carry them are mostly on unfenced utility rights-of-way. The conductors use the air as insulation. The structures and tension between conductors make sure they are high enough above ground to meet safety standards. Structures are constructed on footings in the ground and are difficult to dislodge.

While the likelihood for sabotage or terrorist acts on the Proposed Action or alternatives is difficult to predict given the characteristics of the Project, it is unlikely that such acts would occur. If such an act did occur, it could have a significant impact on the transmission system or electrical service because the North Bonneville-Midway 230-kV transmission line is an integral part of BPA’s transmission system; however, any impacts from sabotage or terrorist acts likely could be quickly isolated. The Department of Energy, public and private utilities, and energy resource developers include the security measures mentioned above and others to help prevent such acts and to respond quickly if human or natural disasters occur.

3.18 ADVERSE EFFECTS THAT CANNOT BE AVOIDED

Implementation of the Proposed Action would result in some adverse impacts that cannot fully be avoided even with implementation of mitigation measures. However, most of these impacts would occur during the construction phase of the Proposed Action and thus would be temporary. For the proposed wind Project, the unavoidable adverse impacts include:

- Short-term earth-disturbing activities of 108 acres during construction (56 acres of permanent disturbance and 52 acres of temporary disturbance). These impacts, while unavoidable, would take place in landscape of managed timber lands which has for many years and would continue to be a fragmented environment with ongoing disturbance. During construction, direct mortality to birds could occur through nest disturbance.
• Short-term potential for landslide and erosion during construction and operations.

• Short-term impacts to air quality similar to that of existing logging operations during construction.

• Short-term and localized impacts to water resources during construction and operation of the Project.

• Short-term and minimal risk of unintentional or accidental fire or explosion or discharge to the environment during both construction and operations.

• Short-term and minimal delays in traffic in some areas during construction.

• Short-term and minimal risk of accident during construction.

• Short-term accidental fire, release of hazardous materials, or injury could occur during construction, operation, or decommissioning of the Project.

• Short-term noise impacts during construction is exempt so long as it occurs during daytime hours, and operation noise is predicted to be less than the nighttime threshold of 50 dBA L_{eq} per Washington State and Skamania County regulations.

• Long-term visual impact to surrounding areas where turbines were visible, including some areas inside the Columbia River Gorge National Scenic Area.

• Long-term mortality to birds and bats through turbine collisions.

• Long-term yet minor unavoidable adverse impacts to energy or natural resources through the consumption of fossil fuels for construction and maintenance of the Proposed Action.

• Long-term socioeconomic impacts are considered to be beneficial as the Project would provide employment during construction and operation. Additionally, increased tax revenues would offset the impacts to public services and utilities.

• Permanent loss, temporary disturbance and fragmentation of existing habitat for a number of wildlife species.

Under the No Action Alternative, although many of the potential impacts of the Proposed Action would not occur, the existing Project Area would continue to be utilized for commercial forestry operations. Additionally, BPA’s North Bonneville-Midway 230-kV and the Underwood Tap to Bonneville Powerhouse 1-North Camas 115-kV transmission lines would continue to remain in place and would be subject to impacts related to the need for ongoing repairs and maintenance of these existing transmission lines.
4.0 ENVIRONMENTAL CONSULTATION, REVIEW, AND PERMITTING REQUIREMENTS

This chapter addresses federal and Washington state statutes, implementing regulations, and Executive Orders requiring consultation, review, and/or permits or approvals, and discusses the applicability of these requirements to the proposed Project. This EIS is being sent to Tribes, federal agencies, and state and local governments as part of the consultation process for this Project.

Permits and approvals required for the Project construction and operation are listed in Table 4-1 and discussed in more detail in this chapter. Permits and approvals listed in Table 4-1 fall into seven categories: Site Certification Agreement (EFSEC), environmental (NEPA and SEPA), air-related permits, land use approvals, approvals related to the transmission interconnection, consultation, and other required permits. Agencies requiring permits or approvals include EFSEC, Skamania County, BPA, USFWS, National Marine Fisheries Services, Ecology, the Federal Aviation Administration, WSDOT, and WDFW.

4.1 NATIONAL AND STATE ENVIRONMENTAL POLICY ACT

This Draft EIS was prepared jointly by EFSEC and BPA to fulfill the requirements of both Washington’s SEPA (43.21C RCW) and NEPA (42 USC 4321 et seq.). Both of these statutes require state and federal agencies, respectively, that are proposing to take action to assess, consider, and disclose the potential impacts of their proposed actions on the environment. Furthermore, the implementing regulations for both SEPA and NEPA both encourage coordination on combined state and federal actions. WAC 463-47-150 states that “[w]hen [EFSEC] is considering an action which also involves federal actions; it shall attempt to coordinate the two governmental processes so that only one environmental impact statement need be prepared for that proposal.” In addition, 40 CFR 1506.2 encourages the preparation of joint state and federal environmental impact statements to aid in elimination of duplication with state and local procedures. EFSEC and BPA will consider the Project’s potential environmental consequences and comments from agencies, Tribes, and the public when making decisions regarding the proposed Project.

4.2 ENDANGERED SPECIES ACT

The Endangered Species Act of 1973 (16 USC 1536) as amended in 1988, establishes a national program to conserve threatened and endangered species of fish, wildlife and plants, and to preserve the ecosystems on which they depend. The Act is administered by USFWS for wildlife and freshwater species, and by National Oceanic and Atmospheric Administration (NOAA) Fisheries for marine and anadromous species. It defines procedures for listing species, designating critical habitat for listed species, and preparing recovery plans and specifies prohibited actions and exceptions.

BPA = Bonneville Power Administration  
Ecology = Washington State Department of Ecology  
EFSEC = Energy Facility Site Evaluation Council  
EIS = environmental impact statement  
NEPA = National Environmental Policy Act  
NOAA = National Oceanic and Atmospheric Administration  
SEPA = State Environmental Policy Act  
USFWS = US Fish and Wildlife Service  
WSDOT = Washington State Department of Transportation
Section 7 of the Endangered Species Act requires federal agencies to ensure that the actions they authorize, fund, and carry out do not jeopardize endangered or threatened species or their critical habitats. A federal agency is required to consult with USFWS and/or NOAA Fisheries if it is proposing an action that may affect listed species or their designated critical habitat. If listed species or designated critical habitat are present and could be affected by the Proposed Action, Section 7 requires that the federal agency prepare a biological assessment to analyze the potential effects of the action on listed species and critical habitat and make an effect determination for each species. BPA prepared and submitted a Biological Assessment (dated June 8, 2010) to USFWS for informal consultation as provided in Appendix E. The Project has received a concurrence letter from USFWS (July 19, 2010) that the Project “may affect, but is not likely to adversely affect” northern spotted owls, and through concurrence from the USFWS has complied with Section 9 of the ESA as also provided in Appendix E. As described in Section 3.4 Biological Resources, no listed species or critical habitat are anticipated to be affected by the project.

### 4.3 FISH AND WILDLIFE CONSERVATION ACT AND FISH AND WILDLIFE COORDINATION ACT

The Fish and Wildlife Conservation Act of 1980 (16 USC 2901 et seq.) encourages federal agencies to conserve and promote conservation of non-game fish and wildlife species and their habitats. In addition, the Fish and Wildlife Coordination Act (16 USC 661 et seq.) requires federal agencies undertaking projects affecting water resources to consult with USFWS and the state agency responsible for fish and wildlife resources.

As described in Section 4.2, BPA is in the process of consulting with USFWS concerning fish and wildlife resources that could be affected by the proposed Project. In addition, BPA has consulted with WDFW and has incorporated recommendations to avoid and minimize potential impacts to fish and wildlife resources. Mitigation designed to avoid and minimize impacts to fish and wildlife and their habitat is identified in Section 3.4 Biological Resources.

### 4.4 MAGNUSON-STEVENS FISHERY CONSERVATION AND MANAGEMENT ACT

NOAA Fisheries is responsible for ensuring compliance with the Magnuson-Stevens Fishery Conservation and Management Act of 1976. In the exclusive economic zone, except as provided in Section 102, the US claims, and will exercise, sovereign rights and exclusive fishery management authority over all fish and all continental shelf fishery resources. Beyond the exclusive economic zone, the US claims and will exercise exclusive fishery management authority over all anadromous species throughout the migratory range of each such species, except when in a foreign nation’s waters, and all continental shelf fishery resources.

Public Law 104-297, the Sustainable Fisheries Act of 1996, amended the Magnuson-Stevens Act to establish requirements for essential fish habitat descriptions in federal fishery management plans, and to require federal agencies to consult with NOAA Fisheries on activities that may adversely affect essential fish habitat, which can include all streams, lakes, ponds, wetlands, and other viable water bodies and most of the habitat historically accessible to salmon. Activities above impassible barriers are subject to consultation provisions of the Magnuson-Stevens Act.
No species administered under the amended Magnuson-Stevens Act occur in the vicinity of the proposed Project.

**4.5 MIGRATORY BIRD TREATY ACT**

The Migratory Bird Treaty Act implements various treaties and conventions between the US and other countries, including Canada, Japan, Mexico, and the former Soviet Union, for the protection of migratory birds (16 USC 703-712, July 3, 1918, as amended 1936, 1960, 1968, 1969, 1974, 1978, and 1989). Under this Act, taking, killing, or possessing migratory birds or the eggs or nests is unlawful. Most species of birds are classified as migratory under the Act, except for upland and nonnative birds such as pheasant, chukar, gray partridge, house sparrow, European starling, and rock dove.

Potential impacts to migratory birds as a result of the proposed Project are discussed in the Section 3.4 Biological Resources. Although the proposed Project would not be expected to result in a take or killing of migratory bird species within the meaning of the Act, impacts to migratory birds could occur through temporary disturbance both during construction and operation of the Project. Impacts to migratory birds could occur through temporary disturbance during construction. BPA would ensure appropriate mitigating measures are employed to minimize and avoid impacts to migratory birds.

**4.6 EXECUTIVE ORDER 13186, RESPONSIBILITIES OF FEDERAL AGENCIES TO PROTECT MIGRATORY BIRDS**

Executive Order 13186 was issued on January 17, 2001. It directs each federal agency that is taking actions that may negatively impact migratory bird populations to work with the USFWS to develop an agreement to conserve those birds. The protocols developed by this consultation are intended to guide future agency regulatory actions and policy decisions; renewal of permits, contracts, or other agreements; and the creation of or revisions to land management plans. This order also requires that the environmental analysis process include effects of federal actions on migratory birds. On August 3, 2006, the USFWS and the US Department of Energy signed a Memorandum of Understanding to complement the Executive Order. BPA, as part of the Department of Energy, will work cooperatively in accordance with the protocols of the Memorandum of Understanding.

**4.7 BALD AND GOLDEN EAGLE PROTECTION ACT**

The Bald Eagle Protection Act of 1940 prohibits the taking or possessing of and commerce in bald and golden eagles, with limited exceptions (16 USC 668–668d, June 8, 1940, as amended 1959, 1962, 1972, and 1978). The Act only covers intentional acts or acts in “wanton disregard” of the safety of bald or golden eagles.

Potential occurrence of bald eagles in the Project vicinity and potential impacts from the proposed Project are discussed in Section 3.4 Biological Resources. Mitigation measures to avoid and minimize impacts to bald eagle also are identified. The Project would not involve intentional acts or acts in wanton disregard of bald or golden eagles. Any accidental injuries or deaths would be subject to Federal law. Because the project would not involve intentional acts or
acts in wanton disregard of bald or golden eagles, this project is not considered to be subject to compliance with the Act.

4.8 HERITAGE CONSERVATION ACTS

Because of the recognized importance of cultural and historic resources, several laws have been passed to protect and provide appropriate treatment for these resources. In addition, American Indian Tribes are afforded special rights under certain laws and treaties. Laws and orders related to cultural and historic resources include:

- Antiquities Act of 1906 (16 USC 431–433)
- Historic Sites Act of 1935 (16 USC 461–467)
- National Historic Preservation Act (NHPA) of 1966 (16 USC 470 et seq.), as amended, inclusive of Section 106
- Archaeological Data Preservation Act of 1974 (16 USC 469 a-c)
- Archaeological Resources Protection Act of 1979 (16 USC 470 et seq.), as amended
- Native American Graves Protection and Repatriation Act (25 USC 3001 et seq.)
- Executive Order 13007 Indian Sacred Sites
- Interior Secretarial Order 3175 of 1993

Section 106 of the NHPA requires federal agencies to take into account the effects of their undertakings on historic properties, and afford the Advisory Council on Historic Preservation a reasonable opportunity to comment. Historic properties are properties that are included in the Natural Register of Historic Places (NRHP) or that meet the criteria for the Natural Register. If a federal agency plans to undertake a type of activity that could affect historic properties, it must consult with the appropriate State and/or Tribal Historic Preservation Officers to assess adverse effects on identified historic properties. BPA fully respects tribal law and recognizes tribal governments as sovereigns. BPA consults affected tribes about potential cultural and/or other tribal impacts prior to taking project and program actions. As a federal agency, BPA is responsible for conducting NHPA review and Section 106 compliance activities during NEPA environmental review processes. As necessary, BPA’s Tribal Policy of 1996 further commits the agency to policy level government-to-government consultation upon request of tribal policy makers and elected officials to better understand the technical and legal issues necessary to make informed decisions. BPA’s 1996 government to government agreement with 13 federally-recognized Native American Tribes of the Columbia River basin provides guidance for the Section 106 consultation process with the Tribes.
The NHPA amendments specify that properties of traditional religious and cultural importance to a Native American Tribe (also known as Traditional Cultural Properties) may be determined to be eligible for inclusion on the NRHP. In carrying out its responsibilities under Section 106, a federal agency is required to consult with any Native American Tribe that attaches religious or cultural significance to any such properties.

The Native American Graves Protection and Repatriation Act requires consultation with appropriate Native American Tribal authorities prior to excavation when human remains or cultural items (including funerary objects, sacred objects, and cultural patrimony) on federal lands or for projects that receive federal funding are found. The Act recognizes Native American ownership interests in some human remains and cultural items found on federal lands and makes illegal the sale or purchase of Native American human remains, whether or not they derive from federal or Indian land. Repatriation, on request, to the culturally affiliated tribe is required for human remains.

Executive Order 13007 addresses “Indian sacred sites” on federal and tribal land. “Sacred site” means any specific, discrete, narrowly delineated location on federal land that is identified by a Tribe, or a Tribal individual determined to be an appropriately authoritative representative of a Native American religion. The site is sacred by virtue of its established religious significance to, or ceremonial use by, a Native American religion, provided that the tribe or appropriately authoritative representative of an Indian religion has informed the agency of the existence of such a site. This order calls on agencies to do what they can to avoid physical damage to such sites, accommodate access to and ceremonial use of Tribal sacred sites, facilitate consultation with appropriate Native American Tribes and religious leaders, and expedite resolution of disputes relating to agency action on federal lands.

The American Indian Religious Freedom Act protects and preserves to American Indians their inherent right of freedom to believe, express, and exercise traditional religions. BPA has identified the Yakama Indian Nation as having general concerns about the management of certain areas along the Columbia River Gorge, including the Project vicinity. These concerns include, but are not limited to, access to sites, use and possession of sacred objects, and the freedom to practice sacred worship ceremonies.

In addition to these various laws and directives, the federal government has general trust responsibilities to tribes under a government-to-government relationship to ensure that their reserved treaty rights are protected. Ongoing consultation with the Yakama Indian Nation ensures that their rights are protected.

BPA has consulted with the DAHP as well as with The Confederated Tribes of the Umatilla Indian Reservation, The Cowlitz Indian Tribe, The Confederated Tribes of the Warm Springs Reservation of Oregon, The Nez Perce Tribe of Idaho, The Confederated Tribes and Bands of the Yakama Reservation, and The Columbia River Inter-Tribal Fish Commission pursuant to 36 CFR 800.4(a)(4) under Section 106 of NHPA. These correspondences are provided in Appendix E. for the federal undertaking with the Yakama Indian Nation, the Washington State Historic Preservation Officer, and any other interested parties. This consultation process did not identify any effects to historic properties if any, and will provide for resolution of any impacts with the consulting parties.
Throughout the EIS process, the Applicant has worked to involve and consult with Yakama Nation, including the Chiefs of the Cascade and Klickitat Tribes. Representatives from both tribes participated in site trips conducted in 2009 to provide advice and perspective in developing project alternatives. Initially, the Yakama Indian Nation did not agree with the definition of BPA’s APE. However, the Yakama Nation and BPA have reached an agreement concerning the APE and the Tribe will continue to work with the Applicant when the final micrositing process occurs.

If, during construction, previously unidentified cultural resources that would be adversely affected by the proposed Project are found, the Applicant would be required to follow all required procedures set forth in the NHPA, Native American Graves Protection and Repatriation Act, Archaeological Resources Protection Act, and the American Indian Religious Freedom Act.

### 4.9 ENVIRONMENTAL JUSTICE

Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, states that each federal agency shall identify and address, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low income populations. Minority populations are considered members of the following groups: American Indian or Alaska Native, Asian or Pacific Islander, Black not of Hispanic Origin, or Hispanic if the minority population of the affected area exceeds 50 percent, or is meaningfully greater than the minority population in the Project Area. The Order further stipulates that the agencies conduct their programs and activities in a manner that does not exclude persons from participating in or deny persons the benefits of those programs and activities, and that does not subject persons to discrimination because of their race, color, or national origin.

The proposed Project has been evaluated for disproportionately high environmental effects on minority and low-income populations (see Section 3.13, Socioeconomics). The Project would not result in disproportionately high and adverse effects to minority or low income groups.

BPA has considered all input from persons or groups regardless of race, income status, or other social and economic characteristics. Potentially affected minority populations include American Indian tribes with an interest in the federal lands that could be affected. BPA, with EFSEC as a participant, is consulting with Yakama Indian Nation regarding the potential impacts of the Proposed Action. For more information on these consultations, see Section 4.8, Heritage Conservation, as well as Section 3.10, Historical/Cultural Resources.

### 4.10 STATE, AREA-WIDE, AND LOCAL PLAN AND PROGRAM CONSISTENCY

#### 4.10.1 ENERGY FACILITY SITE EVALUATION COUNCIL

Chapter 80.50 RCW are the laws which the Energy Facility Site Evaluation Council must follow in siting and regulating major energy facilities. WAC Title 463 provides the regulations by which the EFSEC functions under state and federal law. Chapters 80.70 and 80.80 RCW also apply to some energy facilities under EFSEC jurisdiction. For more information on the
consistency of the proposed Project with Skamania County land use regulations, see Section 3.8, Land Use and Recreation.

Chapter 80.50 RCW (Energy Facilities–Site Locations) and Title 463 WAC specify that during the siting of energy facilities such as the Project, EFSEC will specify the conditions of construction and operation. This provision operates to supersede all state and local land use permitting related to energy facility sites that are under EFSEC’s jurisdiction. However, a determination of consistency with local land use regulation is required. In the event that a proposed Project is determined to be inconsistent with local land use regulations, the applicant may request that the Project be regulated at the state level by EFSEC, rather than by the local jurisdiction. Because Skamania County has found the Project to be consistent with its Comprehensive Plan and Zoning Ordinance, the Applicant does not anticipate requesting this type of preemption for this Project. However, if EFSEC were to determine that, notwithstanding the County’s determination, the Project is inconsistent with any element of local land use plans or ordinances, EFSEC retains preemption authority to resolve such inconsistency.

4.10.2 SKAMANIA COUNTY

Skamania County has provided EFSEC with a letter and Resolution 2009-54 stating that the proposed Project would comply with the land use policies and zoning regulations for the vicinity of the proposed Project. (Appendix D)

4.11 COLUMBIA RIVER GORGE NATIONAL SCENIC AREA ACT

The Columbia River Gorge National Scenic Area Act (16 U.S.C. 544-544p) established the Columbia River Gorge National Scenic Area (CRGNSA) to: (1) protect and provide for the enhancement of the scenic, cultural, recreational, and natural resources of the Gorge; and (2) protect and support the economy of the Columbia River Gorge area by encouraging growth to occur in existing urban areas and by allowing future economic development. The Act also authorized creation of the Columbia River Gorge Commission, a bi-state regional planning agency that was created by an inter-state Compact between the states of Washington and Oregon.

The Gorge Commission, the U.S. Forest Service, and the six counties with land in the CRGNSA all work together to implement the provisions of the Act. The Gorge Commission has several responsibilities under the Act, including planning for the CRGNSA, implementation of the CRGNSA Management Plan, and monitoring and hearing appeals of land-use decisions. The local counties and the Gorge Commission are responsible for drafting and enforcing land-use ordinances to implement the Management Plan. The Forest Service administers recreation facilities, assists in resource protection programs, provides technical assistance, and manages National Forest lands within the CRGNSA.

The 292,500 acre CRGNSA extends along the Columbia River from approximately the confluence of the Columbia and Sandy rivers on the west to just past the village of Wishram, Washington on the east. The proposed WREP Project Area is located outside of, but immediately adjacent to, the northern boundary of the CRGNSA near White Salmon, Washington (see Figure 1-1). The Scenic Area comprises three land use classifications: GMAs, SMAs, and Urban Areas. SMAs, which contain the most sensitive resources, are managed by USFS. GMAs include a mixture of historic land uses such as farming, logging, residential, and
cattle grazing. Development on GMA lands is administered by five of the six Gorge Counties and the Columbia River Gorge Commission. Both SMAs and GMAs are subject to local Scenic Area codes deemed consistent with the Scenic Area Management Plan by the Columbia River Gorge Commission and the US Secretary of Agriculture prior to adoption. In Skamania County, Scenic Area development regulations are codified in SCC Title 22.13. Urban Areas (including Cascade Locks, Hood River, Mosier, and The Dalles in Oregon, and North Bonneville, Stevenson, Carson, Home Valley, White Salmon, Bingen, Lyle, Dallesport, and Wishram in Washington) are exempt from Title 22 Scenic Area regulations.

Although the proposed Project thus is in close proximity to the CRGNSA, the CRGNSA Act expressly states that:

Nothing in [this Act] shall . . . establish protective perimeters or buffer zones around the scenic area or each special management area. The fact that activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas.

See (16 USC § 544O(a)(10). Accordingly, because the proposed Project is located outside of the CRGNSA, the provisions of the CRGNSA Act do not apply to the proposed Project.

4.12 FARMLAND PROTECTION POLICY ACT

The Farmland Protection Policy Act (7 USC 4201 et seq.) directs federal agencies to identify and quantify adverse impacts of federal programs on farmlands. The Act’s purpose is to minimize the number of federal programs that contribute to the unnecessary and irreversible conversion of agricultural land to non-agricultural uses.

The location and extent of prime and other important farmlands is designated by the Natural Resource Conservation Service and can be found in their soil survey information. Prime farmland refers to land that has the best combination of physical and chemical characteristics for producing food, feed, forage, fiber and oil seed crops. None of the lands within the Project Area boundary are considered to be prime farmland, and the access road also does not cross or affect other farmlands.

4.13 RECREATION RESOURCES

BPA used the Wild and Scenic River inventory of listed and proposed rivers (16 USC Sec. 1273 [b]) qualifying for Wild, Scenic, or Recreation River status to evaluate recreational resources and impacts. The Project Area area does not contain and will not cross any listed segments. Impacts to the visual quality in the vicinity of the Columbia River Gorge National Scenic Area are discussed in Section 3.9, Visual Resources.

The Northwest Power Planning Council’s Protected Area Amendments to the Pacific Northwest Electric Power Planning Council Designation Act of 1980 are not applicable to the Project.

No National Recreation or National Scenic Trails identified in the National Trail System (16 USC Sec. 1242–1245) lie within the Project Area. Two national trails, the Lewis and Clark
National Historical Trail and the Oregon National Historic Trail, are located within 5 miles of the Project Area. These trails roughly follow SR 14 and I-84, respectively. Within 5 miles of the site, the White Salmon River is designated as a Wild and Scenic River, and within 25 miles, the Klickitat River is also so designated.

### 4.14 CLEAN WATER ACT

The Clean Water Act (933 USC § 1251 et seq.) regulates discharges into waters of the United States:

- **Section 401.** A federal permit to conduct an activity that causes discharges into navigable waters is issued only after the affected state certifies that existing water quality standards would not be violated if the permit were issued. No discharges to navigable waters are proposed as part of the Project.

- **Section 402.** This section authorizes storm water discharges under NPDES. The State of Washington was delegated the NPDES program under the Clean Water Act in 1974, and has adopted its own NPDES program. The Applicant would file an NOI to obtain coverage under the Washington general permit and would prepare a SWPPP. The SWPPP will address stabilization practices, structural practices, stormwater management, and other controls (see Section 3.1 Geology and Section 3.2 Water Resources).

- **Section 404.** Authorization from the US Army Corps of Engineers under Section 404 is required when there is a discharge of dredge or fill material into waters of the US, including wetlands. As discussed in Section 3.4 Biological Resources, the proposed Project would not cause any impact to wetland areas.

### 4.15 FLOODPLAIN / WETLANDS ASSESSMENT

The U.S. Department of Energy mandates that impacts to floodplains and wetlands be assessed and that alternatives for protecting these resources be evaluated in accordance with Compliance with Floodplain/Wetlands Environmental Review Requirements (10 CFR 1022.12), and Federal Executive Orders 11988 and 11990.

Section 3.4 Biological Resources evaluates Project impacts on floodplains and wetlands. The Project Area is not within a floodplain as determined from Flood Insurance Rate Maps published by the Federal Emergency Management Agency. Wetlands occur within the Project Area boundary but would not be affected by the construction and operation of the Project. This evaluation serves as the notice of floodplain/wetlands involvement for this Project.

### 4.16 COASTAL ZONE MANAGEMENT ACT

As an agency of the federal government, BPA follows the guidelines of the Coastal Zone Management Act of 1972 (16 USC Sections 1451–1464) and would ensure that projects would be, to the maximum extent practicable, consistent with the enforceable policies of the state management programs. The proposed Project is not in the coastal zone, nor would it directly affect the coastal zone.
4.17 THE SAFE DRINKING WATER ACT

The Safe Drinking Water Act (42 USC Section 200f et seq.) protects the quality of public drinking water and its source. BPA would comply with state and local public drinking water regulations. The proposed Project would not affect any sole source aquifers or other critical aquifers, or adversely affect any surface water supplies.

4.18 CLEAN AIR ACT

The Clean Air Act, as revised in 1990 (PL 101-542 [42 USC 7401]), requires the EPA and individual states to carry out a wide range of regulatory programs intended to assure attainment of the National Ambient Air Quality Standards.

The proposed the Project lies entirely in Skamania County, Washington. As discussed in Section 3.2 Air, the county is an attainment area within the National Ambient Air Quality Standards for all criteria pollutants. Impacts to air quality would be limited primarily to the construction period and would be minor, and would conform to state and federal CAA regulations. See Section 3.2 Air Quality for a complete analysis and discussion of this issue.

4.19 GLOBAL CLIMATE CHANGE

Global climate change is an increase in the average temperature of the Earth’s surface. Since the late 1800s, data shows that the global average temperature has increased about 0.7 to 1.4 degrees F (0.4 to 0.8 degrees C), and some projections estimate that the average temperature will rise an additional 2.5 to 10.4 degrees F (1.4 to 5.8 degrees C) by 2100 (NASA 2009). A majority of scientists who study climate have concluded that human activities are responsible for most of this warming primarily through emission of certain gases that enhance Earth's natural greenhouse effect. Gases that absorb infrared radiation and prevent heat loss to space are called greenhouse gases. These gases include water vapor, carbon dioxide, methane, nitrous oxide, nitrogen oxides, non-methane volatile organic compounds, and stratospheric ozone-depleting substances such as chlorofluorocarbons.

The clearing of large areas of vegetation from the Earth’s surface is also believed to contribute to global climate change because trees and other plants remove carbon dioxide from the air during photosynthesis, the process they use to produce food. Removal of vegetation contributes to the buildup of carbon dioxide by reducing the rate at which the gas is removed from the atmosphere and by the decomposition of dead vegetation.

Operation of the proposed Project would not generate emissions of gases (such as carbon dioxide) that contribute to global climate change, other than small amounts of emissions from vehicles used for site access and maintenance activities.

About 26 acres of tall-growing conifer vegetation would be cleared for the Proposed Action. The removal of this vegetation would result in a net reduction in the collectors of carbon in the Project Area. However, because the amount of clearing would be extremely small, and because low-growing vegetation would regrow in cleared areas, the proposed Project's contribution to global climate change would be negligible to nonexistent.
4.20 POLLUTION CONTROL ACTS

Several pollution control acts potentially apply to the proposed Project, depending on the exact quantities and types of hazardous materials that may be stored on site. Regulations would be enforced by EFSEC, and development of a Hazardous Materials Management Plan in accordance with the Uniform Fire Code may be required by local fire districts.

The Resource Conservation and Recovery Act, as amended, is designed to provide a program for managing and controlling hazardous waste by imposing requirements on generators and transporters of this waste, and on owners and operators of treatment, storage, and disposal facilities. Each treatment, storage, and disposal facility owner or operator is required to have a permit issued by EPA or the state. Typical construction and maintenance activities in BPA’s experience have generated small amounts of these hazardous wastes: solvents, pesticides, paint products, motor and lubricating oils, and cleaners. Small amounts of hazardous wastes may be generated by the Project. These materials would be disposed of according to state law and the Resource Conservation and Recovery Act.

The proposed Project would not generate large amounts of solid waste.

The Toxic Substances Control Act is intended to protect human health and the environment from toxic chemicals. Section 6 of the Act regulates the use, storage, and disposal of polychlorinated biphenyls (PCBs). BPA adopted guidelines to ensure that PCBs are not introduced into the environment. Equipment used for this Project will not contain PCBs. Any equipment removed that may have PCBs will be handled according to the disposal provisions of the Toxic Substances Control Act.

The SPCC Act is intended to prevent discharge of oil into navigable waters of the US or adjoining shorelines, as opposed to response and cleanup after a spill occurs. Facilities subject to the Act must prepare and implement an SPCC Plan to prevent any discharge of oil into or upon navigable waters or adjoining shorelines. Because the proposed Project does not include the storage of large amounts of oil, the Project is not subject to this Act. However, EFSEC may likely require the preparation of an SPCC Plan for the Project.

The Federal Insecticide, Fungicide and Rodenticide Act registers and regulates pesticides. BPA uses herbicides (a kind of pesticide) only in a limited fashion and under controlled circumstances. Herbicides are used on transmission line rights of way and in substation yards to control vegetation, including noxious weeds. When BPA uses herbicides, the date, dose, and chemical used are recorded and reported to state government officials. Herbicide containers are disposed of according to Resource Conservation and Recovery Act standards.

If a hazardous material, toxic substance, or petroleum product is discovered, and may pose an immediate threat to human health or the environment, BPA requires that the contractor notify the Contracting Officer’s Technical Representative immediately. Other conditions such as large dump sites, drums of unknown substances, suspicious odors, stained soil, etc., also must be reported immediately to the Technical Representative, who will coordinate with the appropriate personnel within BPA. In addition, the contractor will not be allowed to disturb such conditions until the Contracting Officer’s Technical Representative has given the notice to proceed.
4.21 NOISE CONTROL ACT

The Federal Noise Control Act of 1972 (42 USC 4901) requires that federal entities, such as BPA, comply with state and local noise requirements. The EPA has established a guideline of 55 dBA for the annual average $L_{dn}$ in outdoor areas. In computing this value, a 10 dB correction (penalty) is added to night-time noise between the hours of 10 PM and 7 AM.

WAC 463-62-030 states that energy facilities shall meet the noise standards established in Chapter 70.107 RCW, also known as the Noise Control Act of 1974, as implemented in the requirements of WAC 173-60. SCC Title 8 Chapter 22: Noise Regulations identifies limits and exceptions specific to noise in Skamania County. SCC 8.22 was adopted pursuant to, and is consistent with, WAC 173-60. Depending on the classification of receiving properties, the noise limits range from 50 dBA to 70 dBA.

Traffic on public roads, aircraft, and railroad traffic are exempt from the applicable environmental noise limits. Construction activities also are exempt from the noise regulations during daytime hours.

The Project would operate at or below existing state noise limits. The facilities would be designed to meet the limits for the worst case, that is, at night, at the edge of the right-of-way, a limit of 50 dBA. See Section 3.7 Noise for detailed analysis of this issue.

4.22 NOTICE TO THE FEDERAL AVIATION ADMINISTRATION

The Federal Aviation Administration requires a Project Proponent to submit its designs for approval if a proposed structure is taller than 200 feet from the ground, if a conductor is 200 feet above the ground, or the structures are within the approach path of an airport. Final locations, structures, and structure heights would be required to be submitted to the Federal Aviation Administration for the Project because the proposed turbine heights are over the 200-foot level.

4.23 FEDERAL COMMUNICATIONS COMMISSION

Federal Communications Commission regulations require that transmission lines be operated so that radio and television reception would not be seriously degraded or repeatedly interrupted. Further, the regulations require that the operators of these devices mitigate such interference. No interference with radio, television, or other reception is expected as a result of the proposed Project (Section 3.6 Public Health and Safety). If any such interference were to occur, BPA would comply with the Federal Communications Commission requirements relating to radio and television interference from the proposed Project.

6.0 LIST OF PREPARERS

The Whistling Ridge Energy Project EIS was prepared by the Washington Energy Facility Site Evaluation Council (EFSEC) and Bonneville Power Administration (BPA), with the assistance of URS Corporation (URS), a consulting firm, West Inc., Northwest Wildlife Consultants, GeoDataScape, and Carroz Consulting. In addition, ENTRIX Consulting was retained by Washington EFSEC to provide an independent, third-party review of the EIS for SEPA and NEPA compliance. The following lists those individuals who participated in the preparation of this EIS. Consultant disclosure statements required under NEPA (see 40 CFR 1506.5(c) and 10 CFR 1021.310) are included in Appendix F of this EIS.

6.1 WASHINGTON EFSEC

Al Wright, EFSEC Manager. Mr. Wright has over 40 years experience in the energy and environmental fields. Mr. Wright has been Managing Director of EFSEC since 2010 and is responsible for all facets of EFSEC activities. Before joining EFSEC Mr. Wright was consultant to NW Utilities on hydro-electric operations and power sales contracts. Mr. Wright has also served as Executive Director of the Pacific Northwest Utilities Conference Committee, a NW association of public and private electric utilities. He also served a director of the Oregon Water Resources Board and as the Regional Coordinator for the Mid-Columbia Public Utilities Districts. Mr. Wright holds a Civil Engineering degree from University of California at Berkeley and has completed graduate studies in Watershed Management from Humboldt State College.

Stephen Posner, EFSEC Compliance Manager. Mr. Posner has over 25 years experience working in various environmental regulatory programs. As EFSEC’s Compliance Manager for the last 3 years, Mr. Posner is responsible for managing environmental compliance activities for facilities under EFSEC’s jurisdiction. Mr. Posner also coordinates and participates in the review of applications for site certification. Prior to working at EFSEC, Mr. Posner worked for the California Environmental Protection Agency as a hazardous waste/solid waste compliance inspector. Education: Bachelor’s Degree in Biological Sciences.

Jim La Spina, EFSEC Compliance Specialist. Jim has been a state environmental regulator for almost 14 years. He wrote NPDES Permits for Ecology for 11 years and joined EFSEC in September 2007 as an Energy Facility Siting Specialist. Jim is responsible for coordinating the review of a project proponent’s Application for Site Certification. After the governor approves a proposed project, Jim verifies the Certificate Holder’s compliance with requirements in the Site Certification Agreement. Education: Master’s in Environmental Studies.

6.2 BPA

Andrew M. Montaño, EIS Project Manager, Environmental Protection Specialist. Mr. Montaño has nearly 20 years experience within the environmental field. His primary background was in water quality-related research while working as an Aquatic Biologist with his former agency, the Bureau of Reclamation. Additionally, he has also specialized in toxicology and hazardous wastes site management, nuisance species control, and some fisheries-related activities. His NEPA experience includes projects that proposed modified flow regimes on regulated rivers in the western United States as well his recent experience with transmission-
related projects. Education: MS in Environmental Science and Engineering; BS in General Studies (biology emphasis)

**Amy Freel, Electrical Engineer.** Mrs. Freel has 19 years of experience working at BPA of which she has been an electrical engineer for 14 years. She worked as a Substation Designer for 10 years, a Customer Service Engineer for 1 year, and as a Project Manager for the last 3 years. In her role as an electrical engineer, she designed and managed the installation of high voltage projects from the planning stage through the commissioning stage. Projects include new and up grades to substations and transmission lines 500kV and below. Education: BS, Electrical Engineering

**Hub Adams, Attorney.** Mr. Adams has 20 years of experience preparing environmental documents for compliance with NEPA, state “little NEPA” laws, and other environmental laws. As BPA’s NEPA attorney, he is responsible for ensuring NEPA compliance for BPA’s activities and assisting in the preparation of EISs and other NEPA documents. Prior to BPA, he worked as an environmental consultant managing and preparing joint NEPA/state EISs, other environmental documents, and project permitting processes for a variety of proposed projects, including complex energy, mining, and transportation projects. He is a member of the American Planning Association (APA) and the American Institute of Certified Planners (AICP). Education: JD, Certificate in Environmental and Natural Resources Law; BA, Urban and Regional Planning.

### 6.3 CONSULTANTS

#### 6.3.1 URS CORPORATION

**Katy Chaney, Project Manager.** Ms. Chaney has over 27 years of experience. As vice president and manager of URS’s Pacific Northwest environmental services, her management responsibilities include environmental impact statements, permitting efforts, and planning and siting studies. Education: BA, Political Science.

**Dale Bennett, JD, Senior Planner.** Mr. Bennett has 20 years of experience managing large and small planning, land use, regulatory, and remote sensing projects.

**Mark DuLaney, Senior Graphics Illustrator.** Mr. DuLaney has over 30 years of experience in graphic illustration and design. He has experience using Corel Draw and Corel Photo Paint, PageMaker, and Power Point. Education: Air Force 223X1 course in Technical Illustration and drawing classes at The New School of Visual Concepts.

**David Every, PhD, Senior Ecologist.** Dr. Every has over 30 years of experience as an environmental consultant on wetland and terrestrial ecological issues throughout the United States. Education: PhD, Botany; MS, Botany; BS, Zoology.

**Mike Kelly, Senior Archaeologist.** Mr. Kelly has 27 years of experience in cultural resource management and has been responsible for directing numerous archaeological investigations throughout the Pacific Northwest, California, and the Great Basin. Education: MA, Anthropology; BA, Anthropology.
Louise Kling, Ecologist and Environmental Planner. Ms. Kling has over 15 years of experience in fisheries and wildlife research, with an emphasis on disturbance ecology. She is well versed in survey methods used to quantify a variety of taxa, including terrestrial and aquatic habitat. She has implemented and managed projects for public agency, university, and private sector clients. Her analytical skills include a wide range of multivariate statistical methods and spatial analysis using GIS. For the past three years, she has focused on visual resource assessment and ecological design, land use evaluation, and environmental justice in support of the NEPA process. Her experience in visual resources assessment includes BLM, USFS, FHWA, and US Army Corps of Engineers methodologies and management of georeferenced photosimulation production. Her expertise has been applied to energy facilities siting, energy transmission, pipeline and transportation projects. In addition, she currently serves as a visual resources technical advisor to the Columbia River Gorge Vital Signs Indicator Project.

Sarah McDaniel, RPA, Staff Archeologist. Ms. McDaniel provides technical support for URS Corporation’s cultural resources program in the Pacific Northwest Region and California. Responsibilities include archaeological site identification, recordation, and evaluation; historic resource documentation; and preparation of summary reports for compliance with federal and state regulations. Ms. McDaniel has six years of experience in cultural resources management and archaeological investigations.

Dan Meier, Engineering Geologist. Mr. Meier is a Certified Engineering Geologist located in Portland, Oregon. He has over 17 years of professional geologic experience in the western United States. His specialties include on-site geologic mapping, subsurface exploration, as-constructed geologic mapping, construction inspection, interpretation of field data, and preparation of maps and reports. He is experienced in seismic hazard evaluations, landslide evaluations, engineering geology and construction management and inspection.

Dautis Pearson, Environmental Planner. Mr. Pearson is a Senior Planner, NEPA, Endangered Species Act, and Federal/State agency and private compliance specialist. He has 23 years of experience in land management planning; interdisciplinary and interagency team leading and facilitation, and NEPA/SEPA environmental preparation. Dautis’ experience with all federal agencies’ NEPA and Endangered Species Act process provides great insight into various agency directions for collaboration and streamlining. He has 12 years of experience with USFS as a Land Use Planning Specialist and has supported or managed several energy and transmission related or linear projects. Education: BS, Biology; Riparian and Fire Ecology; Forestry; Silviculture.

Mark Storm, Senior Noise Control Engineer. Mr. Storm has over 18 years of experience managing tasks for environmental noise regulation review, field surveys, acoustical impact assessment, mitigation planning and compliance evaluation for various energy project types such as solar-to-thermal, wind turbine, biomass and natural gas. He is INCE board certified.

Jeff Walker, Botanist and Wetland Biologist. Mr. Walker has over 10 years of experience as a botanist. He has conducted vascular and nonvascular plant surveys, performed monitoring of rare plant populations, and conducted wetland delineations and evaluations. Education: BS, Botany and Environmental Studies.
6.3.2 WEST, INC

Kimberly Bay. Ms. Bay has 9 years of experience working primarily on the coordination of the data and reports for wind-energy projects. This task includes data and database management, data quality assurance/quality control, data analysis, and finally compiling the results for the reports. She has experience with most statistical computer packages including SAS, R, SPLUS, and SPSS, the database application ACCESS, and the GIS application ARCVIEW.

Greg Johnson. Mr. Johnson has over 22 years of consulting experience in wildlife and ecological studies. He is a Certified Wildlife Biologist through The Wildlife Society, a Professional Wetland Scientist through the Society of Wetland Scientists, and a certified Senior Ecologist through the Ecological Society of America. His specialty areas include wildlife research with an emphasis on contaminants and wind power development; endangered species; wetland delineation, mitigation, and functional value assessment; and vegetation sampling. He has supervised 17 field studies to assess effects on terrestrial and aquatic wildlife of pesticides and other contaminants throughout the US. Over the last 14 years, he has studied wildlife-windpower interactions at proposed or existing wind energy facilities in 16 US states and Alberta, Canada, and is currently Project Manager for the first large-scale greater sage-grouse telemetry study to evaluate impacts of wind energy development on this species.

Tamara Enz, Research Biologist. Tamara Enz is a project manager and biologist for WEST. After becoming fluent in Japanese, Tamara learned the more challenging language of botanical terms, earning a Master’s of Science in plant biology at the University of Massachusetts, Amherst. Working throughout New England, Puerto Rico, and Montana, Tamara conducted community and wetland delineations and habitat suitability studies, coordinated rare plant searches, and participated in numerous research projects ranging from genetics studies to weed control. She has also done extensive bird work, including breeding and migratory bird surveys and point counts, banding, and call playback response surveys in New England, Alaska, Montana, and Canada. Her mammalian experience includes an ice based bowhead whale census in Barrow, Alaska, lynx tracking surveys in Wyoming, and general track surveys in Maine.

Jeffrey Gruver, Research Biologist. Jeff Gruver joined WEST in 2007. Jeff has been involved in bat research since 1996, and has studied bat ecology in the Pacific Northwest, the Rocky Mountains, and the Badlands of southern Alberta. He earned a B.S. in Economics (1993) from Penn State University and an M.S. in Zoology and Physiology from the University of Wyoming (2002). Jeff's M.S. research examined the assemblage of bats near a wind power facility in southern Wyoming in relation to documented bat fatalities at the facility. His PhD research focused on the how physiological constraints influence ecological responses of bats in northern arid climates. Jeff has authored or co-authored scientific publications on topics ranging from species conservation assessments to factors influencing bat fatality risks at wind energy installations.

6.3.3 NORTHWEST WILDLIFE CONSULTANTS, INC

Scott Downes, Bob Gritski, and Karen Kronner. Northwest Wildlife Consultants, Inc. is an environmental consulting firm based in eastern Oregon and Washington. They specialize in wind energy studies and bird, reptile, amphibian and mammal surveys. They are partnering with
the WDFW and Oregon Department of Fish and Wildlife on ferruginous hawk telemetry studies in the Columbia Basin.

6.3.4 GEODATASCAPE, INC

Chris Watson. Mr. Watson, owner of GeoDataScape, has over ten years of experience in providing GIS and visual simulation experience for a variety of projects. He has worked as a field geologist. Education: MS and BS, Geology.

6.3.5 TURNSTONE ENVIRONMENTAL

Jeff Reams, Wildlife Biologist. Mr. Reams is also a partner with Turnstone Environmental Consultants, Inc. for 14 years. He is the senior wildlife biologist and oversees the northern spotted owl, northern goshawk and western gray squirrel surveys. Education: BS Oregon State University

Devin Sahl, Wildlife Biologist. Mr. Sahl has been employed by Turnstone Environmental Consultants Inc. for past 8 years. He served as a wildlife biologist and as the field coordinator on the Whistling Ridge project. He was involved with the northern spotted owl, northern goshawk and the western gray squirrel survey efforts associated with the project.

6.3.6 CARROZ CONSULTING

Katie Carroz, Socioeconomist. Ms. Carroz has 10 years of environmental analysis experience specializing in economic, socioeconomic, environmental justice, demographic, and fiscal analyses, and EIS preparation and coordination. Education: MA, Economics with an emphasis on natural resources; BA, Economics with minor in environmental studies.

6.3.7 CARDNO ENTRIX, INC

Jeremy Pratt, Project Manager. Jeremy Pratt leads the ENTRIX Western Division Environmental Management, Permitting and Compliance practice. Jeremy has more than 30 years’ experience preparing environmental documents for compliance with NEPA, and throughout his career he has focused on managing large-scale, controversial projects to resolve long-standing resource conflicts in complex regulatory environments. Jeremy works with project applicants and local stakeholders concerned with the development, use, protection or environmental management of their sites, communities, or resources. He works easily in both the technical and policy areas to evaluate the environmental effects of proposed actions, programs, or projects; achieve permits and assure regulatory compliance; or develop management plans. Education: BS Interdisciplinary Studies, Evergreen State College; MS Environmental and Energy Sciences, Washington State University.

Jan Aarts, Deputy Project Manager. Mr. Aarts has over 25 years of experience preparing technically sound and legally defensible environmental documents for a wide variety of energy-related projects in the Pacific Northwest. Projects have included wind energy projects, geothermal exploration projects, hydroelectric projects, natural gas pipelines, and high-voltage transmission lines. Mr. Aarts has prepared the full range of NEPA environmental documents, including Notices of Intent, Documented Categorical Exclusions, Environmental Assessments,
Environment Impact Statements, Findings of No Significant Impact, and Records of Decision. He has also prepared the full range of State Environmental Policy Act (SEPA) environmental documents, including Environmental Checklists and Environmental Impact Statements. His technical expertise includes the subjects of land use, regulatory compliance, recreation, socio-economics, community impacts, environmental justice, public services, utilities, and cumulative impacts. He is also experienced at managing the work of other technical experts conducting cultural resource investigations, air and noise studies, hazardous waste investigations, fish and wildlife studies, biological assessments, wetland delineations, stream studies, and mitigation plans.

**Chelsea Ayala, Air Quality Specialist.** Ms. Ayala has over 17 years of regulatory agency, analytical laboratory, and environmental consulting experience. She has served as project manager, deputy project manager, senior reviewer, technical writer, and technical lead for environmental projects throughout California and the United States. Her areas of expertise include air quality, noise, and climate change for a variety of projects, including oil and gas pipelines, electric transmission lines, and water projects. She has experience preparing environmental documentation for Projects involving NEPA and state environmental policy laws and has managed multiple projects for electric transmission lines and prepared environmental analyses for multiple oil and gas projects. Education: BA Environmental Studies, California State University.

**Eliza Ghitis, Geomorphologist.** Eliza Ghitis has a background in coastal, estuarine and fluvial geomorphology, specializing in the ways physical systems interact with ecology. She has managed numerous salmon habitat restoration projects through all phases of design, permitting, implementation, and post-construction monitoring and maintenance. She has conducted ecological and geomorphic studies, including study design, data collection, data analysis and compilation of reports, and preparation of numerous NEPA environmental documents and NEPA technical supporting documents. She is trained in environmental hazard assessment and mitigation, including slope stability, water quality, and relative sea level rise. Education: MS Environmental Geomorphology, Oxford University; BS Earth and Space Sciences, University of Washington.

**Dave Harvey, Historian.** Mr. Harvey has over 30 years of experience in historic preservation, cultural resources management, architectural history, and historic research in the Pacific Northwest, California, Alaska, and Montana, and has assisted federal and state agencies, local governments and utilities, and private architectural and engineering firms in carrying out their cultural resources obligations under sections 106 and 110 of the National Historic Preservation Act (NHPA) and NEPA (EA/EIS). Mr. Harvey has worked closely with federal land management agencies, such as the U. S. Forest Service, National Park Service, Bureau of Reclamation, Bureau of Land Management, and U. S. Army Corps of Engineers throughout the Pacific Northwest and Alaska, where he conducted determination of National Register eligibility studies, Historic American Building Survey/Historic American Engineering Record (HABS/HAER) documentations, assessments of agricultural/early settlement landscapes, and historic land use studies. Education: MA History/Historic Preservation, Western Washington University; BA History and Government, Fairleigh Dickinson University.
Melissa Klungle, Environmental Scientist. Ms. Klungle has ten years of experience in environmental science consulting specializing in terrestrial and aquatic biology, and environmental policy. Ms. Klungle has experience preparing federal and state environmental documentation for energy projects. Education: BS Fisheries and Wildlife Management, Michigan State University.

Gretchen Lebednik, Biologist. Ms. Lebednik has managed numerous restoration, monitoring, and permitting projects. Ms. Lebednik has served as principal biologist or principal botanist in the preparation and review of Biological Assessments/Evaluations, FERC documents, NEPA/CEQA documents, California Energy Commission applications, and mitigation plans for projects in a variety of habitats in California and the Pacific Northwest. She has extensive training and field experience in plant ecology and taxonomy on the Pacific Coast and has performed numerous field investigations in freshwater seasonal wetland, vernal pool, riparian, estuarine, alkali meadow, coastal dune, desert, grassland, foothill woodland, and montane communities in California. Ms. Lebednik has served as principal biologist or principal botanist in the preparation and review of Biological Assessments/Evaluations, FERC documents, NEPA/CEQA documents, California Energy Commission applications, and mitigation plans for projects in a variety of habitats in California and the Pacific Northwest. Education: MS Botany, University of Washington, BA Environmental Biology, University of California.

Darcey Miller, Environmental Biologist. Ms. Miller has twelve years of experience in environmental science consulting, specializing in wetland biology, wildlife habitat, and environmental permitting and policy. She has designed and monitored restoration and mitigation projects, led field efforts for delineations and biological assessments, and coordinated with agencies at all levels to assist clients in obtaining environmental permits. Ms. Miller has experience preparing and editing federal and state environmental documentation for linear and other energy projects. She is a Professional Wetland Scientist and a member of the Society of Wetland Scientists. Education: BS, Environmental Science, additional major in English, University of Mary Washington.

Kirk Ranzetta, Cultural Resource Specialist. Dr. Ranzetta has over fourteen years of private, public, and non-profit sector work experience in cultural resource management, historic preservation, and environmental permitting including NEPA and state environmental policy laws. He has extensive experience in the Pacific Northwest, Midwest, and Mid-Atlantic regions managing, technically reviewing, and completing cultural resource surveys for compliance with Section 106 of the NHPA and NEPA (EA/EIS). He has also served as a technical editor, drafted text, and conducted fieldwork for cultural resource reports and other NHPA and NEPA related-documents. Prior to working at ENTRIX, Dr. Ranzetta served as the Review and Compliance Coordinator for the Oregon SHPO where he consulted with federal agencies on hundreds of projects, evaluated cultural resource reports for technical sufficiency, assisted agencies in the negotiation and preparation of MOAs, and worked to streamline project reviews. This experience included working closely with cultural resources staff from the Oregon DOT, Oregon Energy Siting Council, USFS, FERC, BPA, USFWS, BIA and BLM in Oregon. These reviews were conducted in compliance with Section 106 of the NHPA, Section 4(f), NEPA, HABS/HAER requirements, ORS 358.653, and OAR Chapter 345. Education: PhD Urban Affairs and Public Policy, University of Delaware; MA Urban Affairs and Public Policy, University of Delaware; BA Historic Preservation, University of Mary Washington.
Ryan Shatt, Geologist. Mr. Shatt has over twelve years of experience as a geologist. His expertise includes Remedial Investigations, Human Health Risk Assessments, and Remedial Action. He conducts and manages environmental field investigations including supervision of subsurface drilling operations, monitoring well installation, lithologic identification, soil classification and interpretation, rock coring, borehole geophysics, and sampling of soil and ground water. He also assesses soil and ground water analytical data to evaluate compliance with applicable regulations, conducts pump test analysis and groundwater flow evaluations, performs Phase I ESAs, prepares NEPA environmental documents and manages projects. He has experience as contributing author for soil, geology, and water resources sections for numerous EIS and EA reports. Education: BA Geosciences, Penn State University.

Sandra Slayton, Environmental Scientist. Ms. Slayton has nine years of experience in environmental science consulting specializing in watershed planning, GIS, water quality, floodplain management, and environmental policy. Ms. Slayton has experience preparing federal and state environmental documentation for linear and other energy projects. She has been involved in numerous watershed planning projects including work related to water quality analysis, habitat conservation and enhancement, and hydrologic and hydraulics studies. She is a member of the American Water Resources Association. Education: MA, Ecology, University of North Carolina at Chapel Hill; BA, Environmental Science, University of Virginia.

Rachel Tamigniaux, Project Coordinator. Ms. Tamigniaux is an environmental social scientist with experience in the public, private, and non-profit sectors. She has assisted in the writing, editing and preparation of environmental documents for a wide variety of projects, including wind facilities, oil pipelines, river dredging, and hydroelectric projects. She has experience in the development of National Environmental Policy Act (NEPA) and Washington State Environmental Policy Act (SEPA) environmental documents, specifically Environmental Impact Statements (EISs), as well as experience with Section 106 processes and the development of related documents including Programmatic Agreements (PAs) and various monitoring plans. She has in-depth experience in the public comment management process, particularly for large projects. Ms. Tamigniaux has written planning guidance for environmental conferences for the U.S. Environmental Protection Agency as well as environmental policy and sustainability guidance documents for local non-profits. She is also a contributing author for the websites www.thechicecologist.com; www.theclimatecommunity.com; www.hohm.microsoft.com; and www.tag.microsoft.com. Education: MSc Environmental Social Science, University of Kent, Canterbury; BA Environmental Studies, University of Washington.

Lucy Zuccotti, Archaeologist. Ms. Zuccotti has over 12 years of technical and professional experience as an Archaeologist and Osteologist. Her background includes directing multiple field investigations in Western Washington and conducting background investigations in preparation for fieldwork. She has extensive experience writing reports summarizing research and field results in compliance with federal and state laws and regulations including NEPA and SEPA. Ms. Zuccotti has worked directly with and for Native American governments to mitigate impacts on tribal areas of interest. She is considered an expert in identification and analysis of human remains. Education: MA Anthropology, University of Arkansas; BA Anthropology, Hampshire College.

Olympia, Washington 98504-3172

Subject: SUBMITTAL OF AMENDED APPLICATION 2009-01  
WHISTLING RIDGE ENERGY PROJECT  
SKAMANIA COUNTY, WASHINGTON

Dear Mr. Luce:

Whistling Ridge Energy LLC hereby submits an Amendment to our Application 2009-01 for Site Certification for construction and operation of the Whistling Ridge Energy Project.

The primary revision is the change in site access. We are no longer proposing to use forest service road CG 2930 through the Columbia River Gorge National Scenic Area (CRGNSA). Instead site access is proposed from SR 14 to Cook-Underwood Road, to Willard Road, and then to West Pit Road. West Pit Road is an existing forest road that connects to the western boundary of the project site. West Pit Road is located entirely outside of the CRGNSA and would require some widening. Construction impacts are similar to those already described in the application for project access. No roadway improvements would be required to roads within the CRGNSA.

In addition to the change in road access description and associated roadway lengths, we have made 6 other minor changes to the Application:

- The size of the maintenance and operations yard has been increased from 2 acres to approximately 5 acres.
- A second alternative location has been included for the maintenance and operation yard along the new access road.
- The construction schedule in Section 2.12 has been updated to reflect a later decision date by the Governor, and therefore a later start to construction and operation.
- The zoning for the southern portion of turbine string A has been corrected from R-10 to For/Ag-20 based on testimony from Skamania County during the land use hearing.
- The recreation section has been corrected to add the location of two national trails, the Lewis and Clark National Historical Trail and the Oregon Pioneer National Historic Trail. As pointed out by the National Park Service in their EIS comment letter, both are located within five miles of the proposed facility. These trails roughly follow Highway 14 and Interstate 84, respectively.
The amendment package includes only those sections of the Application that have been revised and is intended to be an errata package to the existing application. Only those sections that have been changed would be replaced.

To assist the reviewers in inserting the amendment package, we have included a listing of the sections as an attachment to this letter. We have also marked the revised text using a strike-out and underline format along with a vertical line in the left hand margin. Text that is not marked as a change is identical to that shown in the March 2009 Application. The vast majority of the revisions result from the new access roadway.

The Amendment to the Application being submitted has been prepared in compliance with the regulations found in Section 463-60 of the Washington Administrative Code. The submittal includes:

(1) Sixty-five (65) copies of the Amendment
(2) Twenty (20) copies of the Amendment in electronic format (Adobe .pdf format)

The Amendment was prepared jointly by Whistling Ridge Energy LLC and URS Corporation. Whistling Ridge Energy LLC hereby certifies that, to the best of our knowledge, all Energy Facility Site Evaluation Council requirements have been reviewed, that the data has been prepared by qualified professional personnel, and the Amended Application is substantially complete.

As stated in Section 1.2, Designation of Agent, in the Application, Mr. Jason Spadaro and Mr. Allen Barkley will continue to serve as the primary points of contact during the review process, along with our legal counsel. Our project team remains ready to meet with you to discuss the application and its review process at your convenience.

Sincerely,

[Signature]

Jason Spadaro, President
Whistling Ridge Energy LLC
Instructions for inserting Amendments into Application 2009-01

PLEASE NOTE: Only revised application sections are included in this package. Please retain unchanged sections, and replace only those sections that are included herein.

INTRODUCTION

Whistling Ridge Energy LLC, a limited liability corporation operating in the State of Washington, seeks a Site Certification Agreement to construct and operate the approximately 75-megawatt (MW) Whistling Ridge Energy Project to generate electricity using wind turbine technology. The project would be constructed in south-central Washington on an approximately 1,152-site approximately 7 miles northwest of the City of White Salmon in Skamania County, Washington. The project would be located on commercial forest land owned by S.D.S. Co., LLC and Broughton Lumber Company in an unincorporated area of Skamania County, outside of the Columbia Gorge National Scenic Area.

I.1 PROJECT SUMMARY

The Whistling Ridge Energy Project is intended to provide both a new source of non-polluting renewable energy in the State of Washington, and to provide much-needed economic development in Skamania County fully compatible with existing land use.

The Whistling Ridge Energy Project is designed to provide low-cost renewable electric energy to meet the growing needs of the Pacific Northwest. Located north of the Columbia Gorge, the project site has been selected primarily for its wind resource and its proximity to Bonneville Power Administration (BPA) power transmission lines, which traverse the site. The transmission lines have adequate capacity for the wind-generated power to be integrated into the power grid system, and the Applicant has made transmission and interconnection requests to BPA. The project site has the further advantage of being in proximity to the Vancouver/Portland metropolitan areas, with the capability of delivering cost-effective renewable energy to these growing communities.

Skamania County is entering its second decade of severe economic downturn, largely a result of the area’s long dependence on timber harvests on public lands. Unlike urban counties with a diversity of businesses, Skamania County has been hard hit by the precipitous decline of timber harvest and associated revenues, and the pending sunset of federal timber payments created as mitigation for the impacts of enforcement of the Endangered Species Act. As described in Section 4.4 Socioeconomics, in 2006, employment in Skamania County averaged 3,116 jobs, of which 2,284 (73 percent) were held by wage and salary workers and 832 (27 percent) by merchants and sole proprietors. Place of work earnings (wages, salaries, and proprietors’ earnings) accounted for approximately one-quarter of total personal income in the county, with income from property (dividends, interest, and rent) and transfer payments (mainly Social Security) making up the balance. The principal sources of employment were local government, accommodation and food services (tourism), federal government, and small scale manufacturing. The data available for this application does not reflect the current economic crisis that has greatly exacerbated Skamania County’s already depressed economy rife with growing poverty, underemployment, and lost jobs.

The annual unemployment rate in Skamania County was 6.6 percent in 2007, and rose to 8.4 percent in 2008, before the full impact of the current recession took effect. Relative to the state as a whole, Washington unemployment rates in 2007 and 2008 were 4.5 percent and 5.5 percent, respectively, having risen from 5.0 percent in 2000 (WESD 2008). Per capita personal income in 2006 in Skamania County was $28,265, which was 74 percent of per capita personal income for the State of
Washington as a whole (BEA 2008). Median household income the same year (2006) was $39,476, or 70 percent of the same measure for Washington State as a whole ($56,184) (WOFM 2008). These statistics indicate relatively lower income in the area near the project when compared to other areas in Washington.

These current unemployment rates and trends and income levels not only reflect that the economy in Skamania County is more depressed than some other areas in Washington, but also that the current national economic slowdown that began in 2008 is affecting areas near the project. The 2008 annual unemployment rate in Skamania County was almost three percentage points higher than the state average, indicating a slow economy.

Fortunately, Skamania County has another natural resource, its winds, that can be developed to benefit local residents and the wider community.

The site on Whistling Ridge, located north of the Columbia River Gorge National Scenic Area and high above the Columbia Gorge, enjoys the same winds that have made the Gorge area a national center of wind power development. These are the same winds that draw wind surfers from around the world to wind swept reaches of the Columbia River near Hood River.

The proposed project site has been used for the last century for commercial forest operations. Most of the areas of the site identified for turbines have been forested recently in general conformance with established timber harvest schedules, and are connected by a network of existing forest roads.

Four major BPA high voltage transmission lines, located in two corridors, cross the site. A Williams Northwest natural gas pipeline is located on the northern edge, their natural compressor station is located to the west, and cellular towers and communications facilities are located nearby. Resource mining in the area has left rock pits in places. In short, the project site is heavily developed, includes no native habitat, and is permanently committed to its use as a utility corridor. The project, once developed, will be a highly compatible companion to sustainable forestry operations on the site, strengthening the landowners’ capability to weather through economic cycles and to keep its 325 forestry and wood products personnel employed.

Approximately fifty 1.2 to 2.5 MW wind turbine generators would be placed on the site and connected to BPA’s existing North Bonneville to Midway 230-kilovolt (kV) transmission line. The winds that traverse the site are robust, with high energy generation due to the well-understood, unique geographic features of the Columbia Gorge area. The site’s potential ability to produce clean electricity so close to urban load, with ready access to transmission and minimal impacts to the natural environment, make it one of the premier as-yet undeveloped wind power sites in the Pacific Northwest.

I.2 DEMAND FOR ELECTRIC POWER IN THE PACIFIC NORTHWEST

Whistling Ridge Energy LLC is proposing to develop a reliable source of clean and cost-effective renewable electrical power in the Pacific Northwest. The Fifth Northwest Electric Power and Conservation Plan was issued by the Northwest Power and Conservation Council in May 2005. The Plan found that Northwest electricity demand was projected to grow at an average annual rate of nearly 1 percent per year, resulting in an over 5,000-MW deficit by 2025 using the medium forecast.
The Fifth Power Plan states that “Renewable resources are also a priority resource in the Northwest Power Act. Like conservation, their potential and cost-effectiveness are sensitive to developing technology and the cost of more traditional generating alternatives... Renewables have potential risk reduction benefits related to their ability to hedge risks of fuel price volatility and the risks of possible measures to mitigate greenhouse gas emissions.”

The Washington Department of Community, Trade and Economic Development in recent reports to the Washington State Legislature has found that: “…the region should begin an aggressive program to capture the large amount of cost-effective conservation that is available and to lay the groundwork for building a large amount of wind generation...” (Washington CTED 2005).

More recently, state policy has been driven by the electorate’s enactment of a Renewable Portfolio Standard that requires all but the state’s smallest utilities to acquire new sources of renewable energy with which to supply consumers with clean electricity. This policy, mandated by the voters, resembles similar (though more aggressive) standards in Oregon and California, and has spurred active development of potential wind energy resources within the state to serve in-state utilities.

The Renewable Portfolio Standard, coupled with load growth in Washington’s urban areas, has prompted investor-owned and public power utilities to seek new sources, most often developed by Independent Power Producers, to meet their resource goals.

According to the American Wind Energy Association, the power of the wind can be imposing. Winds capable of flagging trees, prohibiting crop cultivation or even, on occasion, blowing a semi-trailer truck off the road, can be harnessed to be a non-polluting, never-ending source of energy.

Wind power is a form of renewable energy—energy that is replenished daily by the sun. As the earth is heated by the sun, air rushes to fill the low pressure areas, creating wind power. The wind is slowed dramatically by friction as it brushes the ground and vegetation, so it may not feel very windy at ground level. The kinetic power in the wind, the energy of moving air molecules, may be five times greater at the height of a 40-story building (the height of the blade tip on a utility-scale wind turbine) than the breeze on your face. Meanwhile, the wind may be accelerated by certain types of land forms, so that certain areas of the country may be very windy while other areas are relatively calm. Since our country’s founders tended to build our cities and towns where the wind doesn’t blow strongly, the vast majority of people don’t live in high-wind areas. Yet, when wind power is converted to electricity, it can be sent long distances to serve the needs of the cities and towns where we live.

Wind power is converted to electricity by a wind turbine. In a typical, utility-scale wind turbine, the kinetic energy in the wind is converted to rotational motion by the rotor – typically a three-bladed assembly at the front of the wind turbine. The rotor turns a shaft that transfers the motion into the nacelle (the large housing at the top of a wind turbine tower). Inside the nacelle, the slowly rotating shaft enters a gearbox that greatly increases the rotational shaft speed. The output (high-speed) shaft is connected to a generator that converts the rotational movement into electricity at medium voltage (a few hundred volts). The electricity flows down heavy electric cables inside the tower to a transformer, which increases the voltage of the electric power to the distribution voltage (a few thousand volts). The distribution-higher voltage power flows through underground lines to a collection point where the power may be combined with other turbines. In many cases, the
electricity is sent to nearby farms, residences and towns where it is used. Otherwise, the distribution-voltage power is sent to a substation where the voltage is increased dramatically to transmission-voltage power (a few hundred thousand volts) and sent through very tall transmission lines many miles to distant cities and factories (AWEA 2007).

I.3 REDUCTION OF ENVIRONMENTAL IMPACTS

The project’s location is intended to reduce or eliminate the environmental impacts that would occur if a similar project were to be construction on an undisturbed site:

- The site has been in commercial forest operation for over a century and the majority of the locations proposed for the wind turbines have recently been harvested and reforested, eliminating the need for large amounts of clearing for the purpose of locating a wind project. With this project, the site will remain in sustainable forestry operation.

- The site has existing forest roads that can be used with minimal widening for equipment delivery and for Operations and Maintenance, eliminating the need for new clearing. The site can be accessed from County roads via existing roads, requiring only minor improvements.

- The site is crossed by BPA’s existing North Bonneville to Midway 230-kV transmission line, allowing direct connection through a substation, and eliminating the environmental impacts associated with the need to create a new high voltage transmission line.

- The site is situated in proximity to the Vancouver/Portland metropolitan area, and can provide a robust source of new clean energy to these markets.

- Unlike a fossil fueled power generation plant, wind energy produces no air emissions, and contributes no greenhouse gas emissions

I.3.1 Water Use

The project would have minimal water needs. Small amounts of water would be used during construction for dust control. During operation, the only water needs are for the Operations and Maintenance staff. The staff of eight to nine employees would use less than 5,000 gallons per day for domestic purposes.

I.3.2 Transmission System

Whistling Ridge Energy LLC proposes to connect the project to the BPA electrical transmission grid. These transmission lines are outside the scope of this Application.

I.4 ELEMENTS OF THE PROJECT SUBMITTED FOR APPROVAL

The project submitted for review and approval under Chapter 80.50 Revised Code of Washington includes the following elements:
• An installed capacity of approximately 75 MW of electricity
• Up to fifty 1.2- to 2.5-MW wind turbines
• Electrical transformers
• 34.5 kV collector lines and systems (primarily underground)
• Permanent meteorological towers
• An alternative locations for an Operations and Maintenance facility
• A substation located adjacent to BPA’s existing North Bonneville to Midway 230-kV transmission line
• Approximately 2.4 miles of newly-constructed and 7.27.9 miles of improved roads to provide access to the wind turbine locations during construction and for Operations and Maintenance

In addition to Operations and Maintenance facilities, the project proposes temporary facilities, including construction phase laydown and storage/staging areas, rock crusher and portable concrete batch plant(s). If built, these facilities will be on site or along the access road to the site, minimizing the impacts on the surrounding roads. The project substation would be built on the project site adjacent to BPA’s North Bonneville to Midway 230-kV transmission line, facilitating interconnection with the BPA grid. The proposed electrical interconnection to BPA will provide the access to the regional transmission grid for sales to the wholesale electric market. The development of the proposed interconnection requires a federal action, limited exclusively to the interconnection with the BPA grid.

I.5 SUMMARY OF ENVIRONMENTAL FINDINGS

The project has been planned and designed to eliminate or fully mitigate all environmental impacts. The following is a summary of the elements of the environmental in terms of project design and operation.

I.5.1 Geology, Soils, and Floodplains

The project would have minor and insignificant impacts on earth resources, as described in Section 3.1 of this Application. This includes excavation, grading, trenching, backfill, and compaction associated with site development, the wind turbine foundations, and roadway improvements.

Because surface soils on the project site are considered moderately susceptible to erosion, there is potential for adverse impacts on the site soil in areas of steep topography during grading and foundation construction activities. During the dry season, soils that are disturbed and stripped of vegetative cover may be susceptible to wind erosion. The potential for erosion by wind and water will be minimized through the use of erosion control measures outlined in Section 3.1.7.3 Mitigation Measures.
I.5.2 Air

Because the project uses wind technology to generate electricity, no impacts to air quality would be created during project operation.

During construction, there would be temporary and localized minor impacts from construction vehicle exhaust, similar in nature to those produced by any construction project that involves heavy equipment and transportation of materials to the project site. Construction of the project would produce limited odors associated with exhaust from diesel equipment and vehicles, fugitive dust emissions from construction-related traffic, and additional wind-blown dust as a result of ground disturbance. Whistling Ridge Energy LLC would implement an effective dust control program to minimize any potential disturbance from construction-related dust.

I.5.3 Water

Sections 2.10 Surface Water Runoff and 3.3 Water describe water discharges, water resources, and stormwater management. A Stormwater Pollution Prevention Plan would be prepared and implemented during construction to control the flow of stormwater.

No perennial streams are located in or adjacent to the Whistling Ridge Energy Project. Five drainage ways have been identified on site, ultimately draining to the east of the project site. Runoff is conveyed via these drainage way, and by additional ditches in the southwest portion of the site downslope to perennial streams outside the project site that eventually drain to the Columbia River.

The proposed access road, West Pit Road, crosses one unnamed drainage in the Lapham Creek watershed. This stream had observed flow through the existing culvert under West Pit Road at the time of the July 2009 field visit. However, the surface flow and the channel disappear downstream of the culvert. There is no surface water connection to Lapham Creek. The planned improvements to West Pit Road would cross the unnamed drainage existing roads that would occur inside the Scenic Area would cross one intermittent stream. This stream, drainage has no defined channel and carries water only during runoff events downstream of the existing culvert. It is classified as a Class V stream under Skamania County Code 21.04.020(B). Buffers are established for Class V streams. However, expansion of existing uses is allowed within these water resource buffers. The road improvements in these regulated fish and wildlife protection areas do not exceed the allowed expansion threshold. For a full discussion of fish, wildlife, their habitats, and project impacts to these, please see Section 3.4. Additional details regarding water sources and pathways are identified in Section 3.3 Water and Section 3.5 Wetlands.

Project operations would not require the use of any water for cooling or any other use aside from the limited needs of the Operations and Maintenance facilities. There would be no industrial wastewater stream from the project beyond wastewater from the Operations and Maintenance building discharging to an on-site septic system. The anticipated use is expected to be less than 5,000 gallons per day for kitchen and bathroom use. Potable water intake would be in the form of a well accommodating the Operations and Maintenance facilities’ needs.
I.5.4 Wetlands

No wetlands or wetland indicators were identified within the study area (the project site and previously proposed access roadways). One undelineated wetland is identified as occurring outside the study area perimeter west of turbines C1-C4 (see Figure 3.5-1, Project Site Wetlands in Section 3.5 Wetlands).1

A preliminary review of the National Wetland Inventory maps indicates wetlands occur along State Route (SR) 14 near White Salmon, Washington (Figure 3.5-2, Access Route NWI Wetlands in Section 3.5 Wetlands). As described in Section 4.3 Transportation, only minor roadway improvements to SR 14 would possibly be required at the intersection of SR 14 and Cook-Underwood Road. No wetland impacts are anticipated to occur. The National Wetland Inventory does not show the presence of wetlands along the local secondary and forest roads proposed to be used by the project. As the National Wetland Inventory is based on historic aerial photography interpretations, a field investigation will occur confirmed whether or not that wetlands and other regulated waters of the US or the State may would not be impacted by the project.

I.5.5 Plants and Animals

Construction and operation of the Whistling Ridge Energy Project would require the removal of vegetation in some areas to accommodate roadway construction and improvement, turbine siting, staging, and construction. Because no rare plants were identified in the portion of project site surveyed to date, no project-related impacts on any federal- or Washington State-listed plant species are anticipated during construction or operation of the proposed project.

With the exception of the planned improvement to existing road West Pit Road that would cross one of the intermittent stream, no water bodies on the project site would be impacted. No impacts to aquatic species, their habitat, or designated critical habitat are expected as a result of construction and operation of the proposed facility. Water quality would be maintained during construction and operation of the project by incorporating best management practices.

Construction and operation of the Whistling Ridge Energy Project is expected to have limited impacts on wildlife resources. Project actions would include the construction of permanent roadways, improvement (i.e. widening and resurfacing) of existing roadway, and installation and operation of wind turbines. Impacts to wildlife habitat may result from vegetation removal in forested areas where the proposed roadway and turbine alignment is planned. Vegetation management in areas surrounding each turbine would range from complete removal of vegetation to limitations on tree height.

Three federally-listed or candidate species have the potential to occur within the project site, including northern spotted owl, western gray squirrel, and northern goshawk. Ongoing forest management on lands located within the proposed project site has reduced suitable habitat for these

---

1 The wetland on the project site results from a constructed impoundment according to National Wetland Inventory maps and so is not regulated locally as a critical area according to Skamania County Code Title 21A.04.020(A)(1)(b).
species through fragmentation of mature forest stands.

**Northern Spotted Owl.** The spotted owl prefers forest habitats characterized by multi-layered canopy, and a high incidence of large trees that provide suitable structure for nesting and roosting. No late-seral forests are present within the project site. Further, no spotted owls have been detected in the proposed project site or spotted owl activity centers located in proximity to the proposed project. No impacts to northern spotted owls are expected.

**Western Gray Squirrel.** The gray squirrel prefers habitat where contiguous tree canopy allows arboreal travel in a minimum of a 198-foot (60-meter) radius around the nest (Ryan and Carey 1995). Contiguous forest habitat located on the project site would not persist indefinitely in the absence of the proposed project. The project site also contains very few oak trees, and those that were observed were of small stature (less than 20 feet tall), stunted, and growing in openings on exposed rocky slopes in shallow soils. Acorn crops from oak trees are an important food source for western gray squirrels, and the lack of this primary food source may deter use of the project site by gray squirrels. Because habitat for this species is considered rare or of moderate/poor quality on the project site, impacts to western gray squirrel are expected to be negligible.

**Northern Goshawk.** Goshawks inhabit a wide variety of forest habitats, including true fir, mixed conifer, montane riparian deciduous forest and Douglas fir forests. Goshawk nest sites tend to be associated with patches of relatively large, dense forest located in proximity to water; however, home ranges often consist of a wide range of forest age classes and conditions. Although no goshawks were detected during protocol surveys, individuals were spotted during general avian migration and breeding surveys. Potential impacts to this species may include turbine collision-related mortality or displacement; however, the risk for this species is considered low.

Potential operation-related impacts to avian species include turbine collision and displacement. The data collected from the project site indicate that the area is not within a major migratory pathway, at least during fall migration.

Based on the two seasons of surveys plus two season studies by Klickitat County (Kennedy Jenks 2003), overall use of the project site by golden eagle, northern goshawk, pileated woodpecker, prairie falcon, and willow flycatcher was very low. Adverse impacts to these species are not anticipated. Of the species that were commonly observed, turkey vultures have very low susceptibility to turbine collisions (Orloff and Flannery 1992). To date, this species has not been documented as a turbine fatality in the Pacific Northwest. Vaux’s swifts, western bluebirds, and olive-sided flycatchers were commonly observed flying at rotor-swept heights, and some turbine-related mortality may occur for these species over the life of the project. These collisions would likely be rare, and it is unlikely that the Whistling Ridge Energy Project would have any negative impacts on population levels on and near the project site. Higher numbers of Vaux’s swifts and western bluebirds were recorded during fall migration, whereas olive-sided flycatcher appears to primarily use the project site for breeding.

Waterfowl, waterbirds, and shorebirds were not observed using lands within the project site during this study, and mortality involving this group is expected to be rare.

Based on surveys conducted during high activity periods over two years, it is likely that some bat
mortality would occur during operation; however, mortality estimates are difficult due to our lack of understanding of why bats collide with wind turbines (Kunz et al. 2007, Baerwald et al. 2008). Data collected to date on species composition, activity patterns, and habitat use indicates that adverse impacts to bats are not anticipated as a result of the proposed project. Data collected during 2009 surveys will improve our understanding of bat use and activity patterns, and help to refine our assessment of the degree of impacts.

Mule deer, black-tailed deer, and elk may be displaced temporarily from winter range if the timing of construction activities coincides with use of these habitats. Construction-related displacement is expected to be of short duration. Because data on operational impacts to big game as a result of wind farm operation is limited, it is difficult to predict the impact of the proposed project on wildlife using priority habitats on the proposed project site. Additional coordination with Washington Department of Fish and Wildlife (WDFW) is ongoing, and will continue to address this resource.

I.5.6 Noise

The large distances between much of the project area and potentially affected residences, the temporary nature of construction, and the restriction of construction activities to daytime hours would serve to minimize potential noise impacts from construction activities. Based on the anticipated noise levels and the timing aspects of these impacts, construction noise impacts are expected to be insignificant.

The two nearest residences to the turbines are located 0.48 mile (2,560 feet) and 0.8 mile (4,265 feet) away. In addition, an application has been submitted for a new homesite that would be located approximately 0.38 mile (2,000 feet) from the nearest turbine. Existing noise levels range are 34 to 35 A-weighted decibels (dBA) at night, and 38 dBA during the daytime. With the project, night time noise levels could increase to 39 to 43 dBA, and 40 to 43 dBA during the day. These levels are considered to be low under applicable State standards.

I.5.7 Land Use

The project is consistent with existing and proposed zoning and comprehensive plan designations, and no impacts to land use are anticipated.

I.5.8 Visual Resources

The project has the potential to create low to moderate levels of visual impact at most key viewpoints. Selected viewpoints have been included in Section 4.2.3 Aesthetics of the Application that represent a variety and range of views in the project area. The photos used for the simulations show the worst-case seasonal conditions for visual contrast between the wind turbines and the primarily green and brown landscape backdrop. The period with the least visual contrast is anticipated to occur when there is snow cover and gray skies.

I.5.9 Recreation

It is expected that the project would not “unreasonably diminish the scenic, recreational, and fish
and wildlife values present in the area” (Wild and Scenic Rivers Act, 16 United States Code 1271-1287), so no impacts to wild and scenic rivers would occur. The project would not have a direct impact on any recreation area as measured by impairing access, diminishing use, or restricting planned installations and improvements. The project would affect the visual experience of visitors in some locations (see Figure 4.2-27 Key Recreation Viewing Areas and Recreational Facilities within Approximately 25 Miles). See 4.2.3 Aesthetics for more information about visual and aesthetic qualities and impacts.

### I.5.10 Historic and Cultural Resources

No archaeological sites or historic properties were identified in the project area during the field inventory. All previously documented archaeological sites in the project vicinity are located well outside of the project area. Construction or operation of the proposed facilities would not result in impacts to known/recorded cultural resources. Traditional cultural properties are not known to exist in the project area and no impacts are anticipated.

### I.5.11 Transportation

Access to the proposed project site would be provided through the existing County and private roadway network. Access to all proposed wind tower locations would require road improvements and limited new road construction within the project area. In addition to approximately 7.27.9 miles of existing private logging roads that would require improvement, approximately 2.4 miles of new private gravel access roads would need to be constructed. The new gravel roadways would extend toward and run along the turbine strings, and would be designed and constructed according to the County private roadway standards. The new private roadways that extend toward the turbine strings would be designed for a minimum drivable section width of 25 feet with allowance for side slope and drainage.

The new private roadways that would run along or between the turbine strings would be designed for a minimum drivable section width of 25 feet with an additional 5-foot section on both sides to accommodate drainage and clearance for the project crane that will be on site to assemble the tower sections, the nacelles, and blades. None of the newly constructed roads would need to be paved, but they would require an all-weather driving surface.

During construction, there would be an average of 143 workers on site, and a maximum of 265 workers at the site daily. Estimated traffic volumes include existing local traffic, construction workers and vehicles, and over-size and over-weight trucks. Approximately 65 to 75 percent of the construction labor force would most likely be hired from the cities of Portland and Vancouver. Approximately 25 to 30 percent of the workers would likely be residents of Skamania, Klickitat, and Hood River counties. The respective percentages are based on the relative populations in the cities of Portland and Vancouver when compared to Skamania, Klickitat, and Hood River Counties. All construction workers are expected to commute up to approximately 60 miles each way daily to and from the proposed project site.

During the one-year construction period, there would be over-size and over-weight trucks transporting large wind energy components to the proposed project site throughout the day. Over-
size and over-weight trucks are only expected during an approximate two to three month period when the wind energy components are transported to the proposed project site. It is expected that during the AM peak hour, approximately 30 construction vehicles would travel through the junction of SR 14 and Cook-Underwood Road. During the afternoon peak hour, as many as 10 construction vehicles could travel through this junction.

Peak-hour LOS analyses were completed for the junction of SR 14 and Cook-Underwood Road using estimated 2010-2011 traffic volumes. The results indicate that estimated 2010-2011 traffic volumes, including construction vehicles, would have a minimal impact on the operations of the intersection of SR 14 and Cook-Underwood Road. Delays would increase slightly (approximately 4 to 5 seconds per vehicle) for vehicles turning left or right from Cook-Underwood Road over estimated 2008-2009 operations. The southbound approach on Cook-Underwood Road at SR 14 also has would experience degradation degraded in level of service from A to B over estimated 2008 operations, and would remain at LOS B in 2011 with construction traffic.

I.5.12 Socioeconomics

The project would generate new local employment, additional business for local service and materials providers, and additional tax revenues to Skamania County and the state. The overall permanent socioeconomic impact of the project would be positive.

Construction

During the estimated one-year construction period (excluding engineering, design, specifications, and survey), approximately 330 full-time and part-time workers would be employed at some point during construction. Some of these jobs would not last the entire construction period. The on-site construction work force would peak at approximately 265 workers over the construction period and average 143 workers over the 12 months. Eight to nine permanent full- or part-time Operations and Maintenance staff would be required once the project is operational.

Whistling Ridge Energy Project local procurements² for construction materials, services and equipment leasing associated with construction are projected to total approximately $13.2 million. These procurements would augment the revenues of many construction-related businesses in Skamania County and the three-county area in general. In addition, the consumption spending of local project workers and their households out of their wages and salaries would stimulate the retail trade and services sector of the local and regional economies. Total payroll costs for project construction, including fringe benefits and other labor overhead costs, are projected to be approximately $18 million, of which approximately $4.5 million is expected to be earned in the three-county area including Skamania, Klickitat, and Hood River Counties.

An analysis of the primary and secondary effects of these construction spending streams within the three-county area reveals that indirect and induced value added from construction would be $3.9 million, and that 71 indirect and induced jobs would be attributable to construction. The total economic impact (direct, indirect, and induced) is expected to be $8.5 million in value added and

---

² Local procurements are procurements that would occur with the three-county area including Skamania, Klickitat, and Hood River Counties.
107 jobs (IMPLAN 2008). Project construction would create a total of 107 jobs in the three-county area, which would continue throughout the construction period.

The total cost of construction is estimated to be approximately $150 million. In addition to the local area procurements mentioned above, the Applicant would purchase large amounts of wind power generation equipment from various domestic and foreign suppliers. Depending on legislation currently under consideration in the state legislature, state sales and use tax may be levied only on procurements that are not directly related to electricity generation. Should the state sales tax exemption for wind power be extended, capital equipment such as turbines, transformers, transmission cables, and substation equipment would not be taxable.

The local procurements are estimated to be 10 percent of total procurements (approximately $13.2 million). The majority (estimated at 90 percent) of local procurements would be directly related to electricity generation. Taxable sales due to project construction would therefore be approximately $1.32 million, resulting in $92,400 in sales and use tax revenue for Washington State and Skamania County taxing districts.

The Skamania County sales and use tax rate for the unincorporated area is 7.0 percent, meaning that after the state government’s share of 6.5 percent, a remaining 0.5 percent goes to the County. Due to the project’s location within the unincorporated area of Skamania County, Skamania County would receive $6,600 of the $92,400 in sales and use tax revenues related to project construction. This one-time influx of revenue ($6,600) would represent an increase of one percent when compared to the sales and use tax collected in Skamania County during calendar year 2007 ($630,515) (WDOR 2008). These positive fiscal impacts to the County and the State would be a one-time occurrence resulting from project construction activities.

Modest increases in sales of goods and services would occur during construction, such as local purchases by construction workers. Sales tax revenues resulting from these types of purchases would be beneficial and small within the context of the Skamania County economy.

**Operation**

The estimated gross payroll (including fringe benefits and other payroll overheads) for the operational workforce is $1.5 million, or an average annual labor cost of $167,000 to $188,000 per employee. This is approximately 25 percent higher than the standard industrial wage for this industry in Skamania County (IMPLAN 2008). In addition to the regular operational workforce, a temporary workforce with appropriate skills would be utilized during major maintenance or other non-routine operational work.

Using IMPLAN regional economic modeling software for the power generation and supply industry in the three-county area including Skamania, Klickitat, and Hood River Counties, a wind power facility employing nine full-time workers would have a gross annual operating cost valued at approximately $3.75 million, which would include direct purchases from suppliers (including fuels, maintenance supplies and services, retail goods and professional services). Sales, use and other indirect business taxes on that level of spending are estimated at $200,000 (IMPLAN 2008) per year, which would accrue to state and local government jurisdictions. Employee spending from salaries and wages is estimated at around $900,000 per year, assuming an average local expenditure rate of
70 percent of compensation.

An increase in the tax base equal to the numbers of turbines multiplied by an estimated value of $1.75 million per turbine ($87.5 million) would represent an increase of 6.5 percent in assessed value in the County. Using the average property tax rate for Skamania County of $8.36/$1,000 assessed value (WDOR 2009), the increase in property tax revenue to the County would be $731,500 and would represent a permanent, annual increase of 7.6 percent compared to the amount of property tax collected (current and delinquent) in calendar year 2007 ($9.6 million) (WDOR 2008). Property tax revenues would be higher to the extent that increased wages and economic activity in the County results in higher valued properties.

These additional and permanent annual revenues could help satisfy the need for alternate funds to replace decreasing federal funding. Assuming that the annual tax revenue of $731,500 would be distributed among funds, funds receiving the most revenue would be the State School Fund ($185,281), School District 405 Maintenance and Operations ($149,461), the County Road fund ($115,035), and the Current Expense fund ($111,086). A portion of the State School Fund would be returned to Skamania County for Skamania County schools (L. Moore, personal communication).

### I.5.13 Housing

The approximately 15 percent of the construction workforce that would be specialized craftsmen originating outside of Washington and Oregon would likely have relatively short assignments, so few are expected to bring their families with them when they arrive to work on the project. The population increase in the project area and elsewhere in the three-county area would therefore be limited mainly to these workers for a temporary period of time, plus, during the work week, the non-local workers who would temporarily commute on a weekly basis from the Portland-Vancouver area.

The total estimated number of workers requiring transient housing would be 52 (average) and 97 (peak) over the 12-month construction period, assuming that one-third of the workers from the Portland-Vancouver metropolitan area would commute on a weekly basis and the specialized, temporary staff also would require lodging. These construction workers are expected to seek temporary accommodation in the general vicinity of the project site, and to use motels, trailers, campers, and other forms of transient housing. Approximately 1,082 hotel rooms or RV campsites exist within 25 miles of the project site. Assuming 70 percent occupancy, approximately 325 of these units (313 hotel rooms) would be available at any one time. Assuming a worst-case scenario that workers would want hotel or motel lodging, the peak demand of 97 rooms (assuming, again a worst-case scenario that no workers would share rooms) would represent approximately 31 percent of the available rooms and would therefore not stress the lodging facilities within 25 miles. Construction of the proposed project is not expected to result in a significant impact on transient accommodation availability in the project vicinity, nor is the project expected to affect median housing values, median gross rents, or new housing construction. The applicant has no plans to provide on-site temporary housing for workers or shuttle to or from hotels or other temporary lodging facilities.
I.5.14 Public Services

The influx of construction workers into project area communities on a daily and weekly basis could result in a minor and temporary increase in the demand placed on public service providers. This increase in demand could have a minor and temporary effect on local police departments, providers of emergency medical services, and local fire departments. The contractor would develop emergency plans for project construction.

The impact of project construction on local schools would be at most minor and temporary, as few out-of-state construction workers are likely to be accompanied by families. Construction-related impacts to local utilities also are expected to be minor and temporary.

Response times in the project vicinity are not expected to change due to project construction. Construction trucks would represent additional volume on area roads, but would not deter any emergency vehicles from travel. The project would be constructed entirely within land managed for commercial forestry by the Applicant.

Anticipated water uses during construction include spraying roads for dust control, construction support (such as concrete curing and hydrostatic testing of equipment), and restroom facilities for construction and support workers (estimated average of 143 and peak of 265 workers). Water needed for construction will be purchased by the contractor from an off-site vendor with a valid water right and transported to the project site in water-tanker trucks.

The needs of public service providers are considered in Section 4.3 Transportation. Section 4.2.4 Recreation addresses the potential for impacts on parks and other recreational facilities.

I.6 AGENCY CONTACTS MADE TO DATE

The Applicant has been actively involved in meeting and consulting with local and state agency personnel and with Tribal leaders during the preparation of studies supporting this Application. A summary of the key contacts made to date are listed in this section.

I.6.1 Local Government

- **City of Bingen (January 2009).** Consulted with city administrator to obtain information stating that there are currently no load restrictions in place for Maple Street in the City of Bingen, Washington. Additional information was provided stating that there is a significant increase in traffic volumes during the summer months due to recreational activities in the local area.

- **Klickitat County Public Works Department (January 2009).** Obtained the county “Resolution to Designate Haul Routes” document that could be used as a haul route agreement template for the project by Skamania County. The document was forwarded to Skamania County for review.
• **Skamania County Planning Department.** Three pre-application conferences were held between 2004 and 2008 with Karen Witherspoon and staff (including meetings on March 24, 2006 and August 22, 2007).

• **Skamania County Public Works Department.** Pre-application meetings with County Road Engineer and Building Inspector took place (also present in meeting with Planning Department on August 22, 2007). In addition, the Skamania County Public Works Department Manager, the County Engineer, and the Maintenance Superintendent were consulted to better understand existing roadway conditions, the proposed haul route, and traffic patterns. Information obtained included:
  
  - Contacting Skamania County Public Utility District and Embarq, the local telephone service provider
  
  - Contacting the Burlington Northern Santa Fe Railroad to get a determination on weight restrictions for the tracks that cross Maple Street in the City of Bingen, Washington
  
  - Average daily traffic on Cook-Underwood Road at approximately milepost 12. They also stated that the intersection of Cook-Underwood Road and Kollock-Knapp Road is located at approximately milepost 10 to 10.5
  
  - Recommendation that right of way ownership and easements be determined early on in the planning process
  
  - Requirement that both pre and post construction roadway inspections would need to be conducted along the haul route and that one additional roadway inspection would be required at one year post construction

• **Skamania County Assessor.** Phone and office discussions regarding tax benefits to Skamania County from a potential wind energy project.

• **Skamania Economic Development Council.** Various meetings and discussions regarding economic development and wind energy.

• **Skamania Public Utility District.** Meeting with Commissioners and General Manager (Bob Wittenberg) regarding Skamania Public Utility District system vulnerability to interruption by BPA and benefits to be realized by a potential wind energy project in Skamania County.

• **Underwood Fire District.** Meeting with Fire Commissioners to discuss service agreement for potential wind energy project.

• **Mill A Volunteers.** Meeting with members to discuss possible formation of Fire District and inclusion of potential wind energy project.
I.6.2 State Government

- **Washington Department of Archeology and Historic Preservation.** File search for historic and cultural properties within or near the project site.

- **WDFW.** Meetings with WDFW included:
  - Meeting February 26, 2004 with Bill Weiler, Habitat Biologist and Liane Wedemeter of US Fish and Wildlife Service to discuss survey methods and results of wildlife surveys completed to date, and to discuss future surveys
  - Meeting and site tour November 16, 2007 to discuss survey methods and results of additional wildlife surveys completed to date.
  - Several information exchanges with Area Habitat Biologist (Bill Weiler) to discuss project impacts, review survey results, and discuss survey protocols.
  - Several follow-up meetings with Travis Nelson and Greg Huckel of WDFW during June, July and August of 2009 to continue the discussion and consultation on wildlife.

- **Washington State Department of Natural Resources.** Meeting and discussions with staff regarding application to lease adjoining Department of Natural Resources property for wind energy purposes.

- **Washington State Department of Transportation, Goldendale Office.** Discussed information relating to over-size and over-weight vehicles traveling on SR 14. They stated that the current prohibition for loads in excess of 125 feet including the trailer and load between mileposts 19.00 and 83.53 could be over-ruled for trucks traveling between the SDS Lumber Company facility and the junction of SR 14 and Cook-Underwood Road. The Goldendale office must be contacted prior to any over-size hauls. Pilot cars would be required and Washington State Patrol involvement may be required.

- **Washington State Department of Transportation, Southwest Region Office.** Discussed information relating to Road and bridge restrictions for over-size and over-weight motor vehicles traveling on SR 14 and over-size and over-weight load permit requirements.

I.6.3 Federal Government

- **Bonneville Dam Project Office (January 2009).** Obtained information on lockage length and width parameters as well as average daily usage numbers for the months of May through October.

- **Bonneville Power Administration.** Meetings with BPA included:
  - Meeting on August 22, 2007 as part of pre-application conference with Skamania County Planning Department.
Meeting on September 30, 2008 with Rick Yarde to discuss National Environmental Policy Act process and Tribal consultation.

- **US Fish and Wildlife Service.** Meetings with USFWS included:
  
  - Meeting February 26, 2004 with Bill Weiler, Habitat Biologist and Liane Wedemeter, US Fish and Wildlife to discuss survey methods and results of wildlife surveys completed to date, and to discuss future surveys.
  
  - Ongoing consultation with Ken Berg, Jim Michaels and Mark Ostwald of USFWS to discuss survey work and results.

### I.6.4 Tribal Government

- Letter sent to Yakama Nation Cultural Resources Department.

- Site tour and consultation with local Tribes of Yakama Nation (see Appendix F).

- Communication with Yakama Nation Cultural Resources Program concerning consultation and survey assistance.

### I.6.5 Railroad

- **Burlington Northern Santa Fe Railroad.** Transportation Technology Services provided rail car length, width, and weight parameters as well as transport restrictions between the Port of Longview and the SDS Lumber facility.
SECTION 1.1 DESCRIPTION OF APPLICANT
(WAC 463-60-015)

1.1.1 APPLICANT

This application for a Site Certification Agreement is made for the construction and operation of the Whistling Ridge Energy Project. The Applicant is Whistling Ridge Energy LLC.

This application for a Site Certification Agreement was professionally prepared by URS Corporation under the direction of S.D.S Co., LLC and SDS Lumber Company. These parties believe that the application is substantially complete and meets the requirements established in Chapter 80.50 Revised Code of Washington (RCW) and Title 463 Washington Administrative Code (WAC).

1.1.2 WHISTLING RIDGE ENERGY LLC

Whistling Ridge Energy LLC was incorporated in the state of Washington in February 2009. Whistling Ridge Energy LLC is a special purpose corporation formed to develop, permit, finance, construct, own and operate the Whistling Ridge Energy Project. Whistling Ridge Energy LLC is a Washington corporation formed under Title 23B of the RCW. It is wholly-owned by S.D.S Co., LLC.

Whistling Ridge Energy LLC would own and operate the Whistling Ridge Energy Project and would manage all of the affairs of the project, including activities related to obtaining permits and other approvals required for development of the project. It is anticipated that one or more additional equity participants may join with Whistling Ridge Energy LLC in connection with obtaining permanent financing for the project.

Whistling Ridge Energy LLC has elected to be treated for federal income tax purposes as an S-Corporation. It has no employees. Pursuant to an agreement between Whistling Ridge Energy LLC and S.D.S Co., LLC, staffing is provided by S.D.S Co., LLC, who hires third party consultants and contracts for other goods and services as necessary. Whistling Ridge Energy LLC may reimburse S.D.S Co., LLC for services rendered.

1.1.3 SDS LUMBER COMPANY AND S.D.S CO., LLC

SDS Lumber Company and S.D.S Co., LLC are privately-held corporations, incorporated in the state of Washington. SDS Lumber Company has owned and operated a wood products manufacturing facility in Bingen, Washington continuously since 1946. SDS Lumber Company’s operations include lumber and plywood manufacturing, log handling and transportation, marine transportation and construction, log chipping for the pulp and paper industry, biomass energy generation, and other land development and land use ventures in the Skamania and Klickitat County area. SDS Lumber Company is an affiliated entity of S.D.S Co., LLC. S.D.S Co., LLC owns forest lands in the states of Oregon and Washington. Some of these lands would be utilized for the Whistling Ridge Energy Project in Skamania County.
1.1.4 BROUGHTON LUMBER COMPANY

Broughton Lumber Company is a privately-held corporation incorporated in the state of Washington. Broughton Lumber Company operated a sawmill in Skamania County from the early 1930s until 1988. Broughton Lumber Company currently manages its forest lands to produce logs for sale to various parties. Broughton Lumber owns forest lands in the state of Washington. Some of these lands would be utilized for the Whistling Ridge Energy Project in Skamania County.
SECTION 1.2 DESIGNATION OF AGENT  
(WAC 463-60-025)

All official communications concerning this Application during the application review process should be directed to Mr. Jason Spadaro, President, Whistling Ridge Energy LLC. He is the designated agent for the project and may be contacted as cited below:

Mr. Jason S. Spadaro  
President, Whistling Ridge Energy LLC  
P.O. Box 266  
Bingen, WA 98605  
(509) 493-6103 (phone)  
(541) 490-5013 (cell)  
(509) 493-2535 (fax)  
jasons@sdslumber.com

Mr. Allen Barkley will serve as a secondary contact. Mr. Barkley’s contact information is as follows:

Mr. Allen Barkley  
Wind Power Associates  
PO Box 1267  
931 Pine St.  
Goldendale, WA 98620  
541 993 1707 (phone)  
509 773 5187 (fax)  
abark@gorge.net
SECTION 1.3 ASSURANCES  
(WAC 463-60-075)

1.3.1 INSURANCE

Whistling Ridge Energy LLC would establish and maintain, or cause to be established and maintained, several forms of insurance during the construction and operation of the Whistling Ridge Energy Project. Insurance would be maintained as required by law, customary business practice, and to satisfy third-party participants and lenders. The following coverages would be included:

- Commercial General Liability Insurance:
  
  The construction contractor and subcontractors would be required to carry commercial general liability insurance, including products and completed operations in amounts sufficient to respond to liability and property damage risks arising during the construction and startup phase of the Whistling Ridge Energy Project.

  Whistling Ridge Energy LLC would obtain and maintain in full force and effect, commercial general liability insurance against claims for liability and property damage arising out of the use and occupancy of the premises.

  Whistling Ridge Energy LLC would purchase insurance policies to cover liabilities arising from environmental, casualty, and other major incidents. The insurance industry views facilities such as the Whistling Ridge Energy Project as low to moderate risk. Therefore, high coverage limits are available at reasonable costs.

- Automobile Insurance
  
  The construction contractor and subcontractors would be required to carry automobile liability insurance covering all owned, leased, non-owned, and hired automobiles used during the construction and startup phase of the project.

  Whistling Ridge Energy LLC would obtain and maintain in full force and effect automobile liability insurance covering owned, non-owned, and hired autos.

- Property Insurance
  
  Whistling Ridge Energy LLC would obtain and maintain at all times during the term of construction and operation of the facility, physical damage insurance on the buildings and all improvements that are to be erected on the premises on an “all risk” basis, including coverage against damage or loss caused by earth movement and flood in an amount sufficient to cover any expected losses or damages.

  The potential for damages can be defined. Damages would occur only if engineered safeguards would fail. In many cases, more than one simultaneous failure would be required to produce significant damages. Upon completion of project design,
insurance underwriters would evaluate the design and estimate maximum potential damages due to failure. In some cases design changes may be implemented to reduce the damages. Insurance would then be purchased to cover the maximum expected damages.

- Worker’s Compensation and Washington Stop Gap Liability

Whistling Ridge Energy LLC would fully comply with the statutory requirements for worker’s compensation as required with respect to any employees performing work on the subject property and premises. Whistling Ridge Energy LLC also would insure for their exposure with Employer’s Liability insurance (Washington Stop Gap Liability).

Whistling Ridge Energy LLC would require of the construction contractor and subcontractors working on the project similar compliance with the statutory requirements for worker’s compensation with respect to their employees performing work on the subject property and premises. Whistling Ridge Energy LLC also would require Employer’s Liability insurance for exposure under Washington Stop Gap Liability.

1.3.2 ENVIRONMENTAL IMPAIRMENT

Whistling Ridge Energy LLC and its operator(s) would be responsible, as required by law, for acts of environmental impairment related to the ownership and operation of the Whistling Ridge Energy Project. Such losses may, in some circumstances, be covered by general liability insurance, which Whistling Ridge Energy LLC and the construction contractor would carry. In addition, Whistling Ridge Energy LLC and/or its contracted operator(s) would obtain environmental impairment liability insurance to the extent such coverage is available on a commercially viable basis. This insurance would cover the acts of Whistling Ridge Energy LLC and its operator(s) at the site, consistent with or in excess of then-prevailing industry standards for such insurance in the wind power generating industry. Commercial viability would be determined by reference to the norm of the industry.

1.3.3 SITE CLOSURE BOND

No set-aside from operating funds is anticipated for site abandonment, but Whistling Ridge Energy LLC would obtain a site closure bond in an amount to be determined by Washington State Energy Facility Site Evaluation Council (EFSEC) upon approval of an initial site restoration plan. To the extent site facilities are not otherwise removed, recycled, or salvaged, Whistling Ridge Energy LLC would maintain ongoing responsibility for site facilities and site integrity as the site owner.
SECTION 1.4 MITIGATION MEASURES  
(WAC 463-60-085)

1.4.1 MITIGATION MEASURES

The following summarizes the mitigation measures in Part 3.0 – Natural Environment and Part 4.0 – Built Environment of this application.

1.4.1.1 Section 2.15, Protection from Natural Hazards

Earthquake Hazards

All structures on the site would be built in accordance with the seismic design provisions presented in the 2006 version of the International Building Code (IBC), and the American Society of Civil Engineers 07-05 standard. The site soil is best represented as Stiff Soil (Soil Site Class D). Based on the site location and site conditions described above, we recommend that the values listed in the following chart be used for seismic design of the project in accordance with Section 1613.5.3 of the 2006 IBC. The occupancy category of the proposed structure is assumed III as per Section 1613.5.6 of the 2006 IBC.

<table>

</tr>
</tbody>
</table>

a. Assumes Seismic Use Group III

A visual inspection would be conducted following abnormal seismic activity. These inspections would look for signs of incipient mass movement in those areas identified as potentially susceptible to such failures.

Slope Failure and Mass Wasting

No mitigation measures are required.
1.4.1.2 Section 3.1, Earth

Seismicity

No mitigation measures are proposed beyond adhering to local building codes and standard turbine and foundation design. The proposed facility would comply with the state building code provisions for seismic hazards applicable to the proposed location.

Soils

Site-specific geotechnical engineering evaluations would be conducted prior to design of the project to identify design methods to address the potential impacts presented above. Mitigation of soil impacts at the site would be incorporated into the final design of the foundations and roadways. A SWPPP would be developed prior to construction or modification of any roads or facilities. The SWPPP would be submitted for approval to EFSEC and followed throughout construction at the site.

Topography

No mitigation measures for topography are anticipated at this time.

Unique Physical Features

At this time, no mitigation measures are anticipated. Additional geotechnical investigations for tower foundation design would provide deeper (> 16 feet) subsurface data. If the additional data indicates potential for slope instability, mitigation would be accomplished through engineering or avoidance.

Erosion/Enlargement of Land Area (Accretion)

BMPs and other measures would be taken to mitigate the erosion hazard at the project site.

Erosion control measures for construction at the site are outlined in Sections 2.10.2 and 2.14.1. The sequences and methods of construction activities would be controlled to limit erosion and are summarized below:

- Construction activities would be controlled to help limit erosion. Clearing, excavation and grading would be limited to those areas of the project absolutely necessary for construction of the project. Areas outside the construction limits would be marked in the field and equipment would not be allowed to enter these areas or to disturb existing vegetation.

- The construction contractors would implement the EFSEC-approved Erosion and Sedimentation Control Plan during construction to minimize soil loss due to surface water flows.

- The EFSEC-approved Environmental Protection Control Plan would be implemented to provide adequate maintenance and inspection of the erosion and sediment control
system. The plan specifies that control structures would be inspected at a frequency sufficient to provide adequate environmental protection. Such inspections would increase in frequency during rainfall periods. In addition, supplies including sandbags and channel-lining materials would be stored on site for emergency use.

- Surface runoff would be diverted around and away from cut and fill slopes and conveyed in pipes or protected channels. If the runoff is from disturbed areas, it would be directed to a sediment trap prior to discharge.

1.4.1.3 Section 3.2, Air

The following mitigation measures for construction-related air emissions and dust are proposed:

- All vehicles used during construction would comply with applicable Federal and state air quality regulations
- Operational measures would be implemented, such as limiting engine idling time and shutting down equipment when not in use
- Active dust suppression would be implemented on unpaved construction access roads, parking areas and staging areas, using water-based dust suppression materials in compliance with state and local regulations
- Traffic speeds on unpaved access roads would be kept to 25 mph to minimize dust generation
- Carpooling among construction workers would be encouraged to minimize construction-related traffic and associated emissions
- Disturbed areas would be replanted or graveled to reduce wind-blown dust
- Erosion control measures would be implemented to limit deposition of silt to roadways

No mitigation is proposed for project operations, as there would be no air or odor emissions.

1.4.1.4 Section 3.3, Water

Surface Water Resources (Movement/Quality/Quantity)

Permanent BMPs would be designed and incorporated into the final construction plans and specifications prepared by the site civil design engineer. These permanent BMPs would include erosion and sediment control through site landscaping, grass, and other vegetative cover. All final designs would conform to the applicable Stormwater Management Manual. Non-structural BMPs also would be incorporated into the operations manual including good housekeeping, preventative and corrective maintenance procedures, steps for spill prevention and response, employee training, and inspection and record-keeping procedures.
Runoff/Absorption

The required BMPs are expected to: minimize erosion, control sedimentation, prevent run-on of stormwater onto disturbed areas, and prevent runoff from disturbed areas. One measure may be treatment of stormwater exiting disturbed areas. Construction-phase erosion and sedimentation control BMPs, as described in Section 2.10, Surface Water Runoff, would be implemented to mitigate the expected impacts of soil disturbance. These may include chemical source control, silt fencing, stabilized construction entrances, street sweeping, straw bale check dams, and rock check dams. With implementation of BMPs, no negligible impacts on runoff or on adjacent surrounding properties are anticipated during construction activities. Construction BMPs are described in further detail in Section 2.10, Surface Water Runoff.

Permanent, operations-phase runoff control and water quality enhancement BMPs, also described in Section 2.10, Surface Water Runoff would be implemented to mitigate the expected impacts of increased runoff rate and pollution from vehicle traffic. These BMPs would include stabilized landscaped areas and vegetated ditches or swales, and would provide the necessary control of stormwater runoff.

Groundwater Resources

No impacts have been identified regarding the quantity of water infiltrating the site following construction. BMPs that are recommended for site development include stabilized landscaped areas and vegetated ditches or swales.

Storage of chemicals onsite is minimal; however, the site development plan would require an SPCC Plan that would protect groundwater (See Section 2.9, Spillage Prevention and Control). Therefore, mitigation for groundwater quality impacts is not necessary.

Public and Private Water Supplies

No impacts to public water supplies and no adverse impacts to private water supplies (water wells) are expected. Therefore, no mitigation measures are required.

1.4.1.5 Section 3.4, Habitat, Vegetation, Fish and Wildlife

Habitat and Vegetation

Mitigation for potential impacts resulting from the proposed project includes the following:

- The applicant has commissioned extensive studies by qualified biologists of rare plants and habitats at the project site to avoid impacts to sensitive populations. The results and recommendations of these studies have been incorporated into the proposed design, construction, and operation of the project. In the event that the final project layout includes areas that contain suitable habitat for rare plants which have not previously been surveyed, an additional rare plant survey would be conducted at the appropriate time of year.
The turbine strings have avoided sensitive riparian areas.

Locating wind turbines in an actively-managed commercial forest avoids impacts to higher quality habitats.

To the extent possible, new road construction and associated habitat impacts have been minimized by improving and using existing roads instead of constructing new roads.

Use of certified “weed free” straw bales during construction to avoid introduction of noxious weeds

All temporarily disturbed areas would be reseeded with an appropriate mix of native plant species as soon as possible after construction is completed to accelerate the revegetation of these areas and to avoid the establishment and spread of noxious weed species.

Implementation of a noxious weed control program, in coordination with the Skamania County Noxious Weed Control Board, to control the spread and prevent the introduction of noxious weed species.

**Fish**

Section 3.3, Water, lists the project BMPs that would be incorporated to protect water quality and quantity. Pursuant to an erosion control plan for the project and an NPDES permit, drainage improvements would be made as needed. All temporarily disturbed areas would be regraded and reseeded with an appropriate mix of native plant species to restore vegetation after the construction phase is completed.

**Wildlife**

The primary mitigation goal for the Whistling Ridge Energy facility is to avoid sensitive wildlife resources when siting turbines and access roads. Because of the relatively small footprint of wind energy facilities and the flexibility of the process, it is likely that avoidance can be achieved. Wind turbines would also be sited in areas already actively managed for timber harvest. New road construction would be minimized by improving and using existing roadways. All temporarily disturbed areas would be regraded and reseeded with an appropriate mix of native plant species to restore vegetation after the construction phase is over.

Mitigation for potential impacts resulting for the proposed project includes the following sequentially-performed actions:

- Rectify the impact by repairing, rehabilitating, or restoring the affected environment in consultation with relevant wildlife agencies.

- Conduct thorough analysis of sensitive natural resources to avoid impacts and increase avoidance during micrositing.
• Implement a two year minimum post-construction mortality study

• The Applicant plans to convene a Technical Advisory Committee to evaluate the mitigation and monitoring program and determine the need for further studies or mitigation measures. The Technical Advisory Committee would be composed of representatives from WDFW, USFWS, Skamania County, and the Applicant. The role of the Technical Advisory Committee would be to coordinate appropriate mitigation measures, monitor impacts to wildlife and habitat, and address issues that arise regarding wildlife impacts during construction and operation of the project. The post-construction monitoring plan would be developed in coordination with the Technical Advisory Committee.

• Implement project design features that would minimize project impacts, including:
  - Installing tubular steel turbine towers to eliminate perching opportunities provided by lattice towers
  - Burying electrical lines between turbines and from turbine strings to substation
  - Using the minimum amount of turbine lighting required by the FAA
  - Installing newer generation up-wind turbines

1.4.1.6 Section 3.5, Wetlands and Jurisdictional Waters

No impacts to wetlands are expected to occur and therefore no mitigation measures would be required.

1.4.1.7 Section 3.6, Energy and Natural Resources

No impacts to energy and natural resources are expected to occur and therefore no mitigation measures would be required.
1.4.1.8 Section 4.1, Environmental Health

Noise

Construction

Construction would generally occur only during daytime hours to reduce the potential for noise impacts from this activity. Construction noise is exempt from Washington noise limits during daytime hours. To ensure that construction noise emission assumptions relied upon herein are valid and acoustical design goals are met by the project during construction, the following mitigation measures are proposed:

- All noise-producing project equipment and vehicles using internal combustion engines would be equipped with mufflers, air-inlet silencers where appropriate, and any other shrouds, shields, or other noise-reducing features in good operating condition that meet or exceed original factory specification. Mobile or fixed “package” equipment (e.g., arc-welders, air compressors) would be equipped with shrouds and noise control features that are readily available for that type of equipment.

- All mobile or fixed noise-producing equipment used on the project that is regulated for noise output by a local, state, or federal agency, would comply with such regulation while in the course of project activity.

- The use of noise-producing signals, including horns, whistles, electronic alarms, sirens, and bells, would be for safety warning purposes only. Unless required for such safety purposes, and as allowable by applicable regulations, no construction-related public address, loudspeaker, or music system would be audible at any adjacent noise-sensitive land use.

- The EPC Contractor would implement a noise complaint process and hotline number for the surrounding community. Whistling Ridge Energy LLC would have the responsibility and authority to receive and resolve noise complaints.

Operation

The noise modeling analysis indicated that the noise levels at the three closest residences (located 0.38, 0.48 and 0.8 mile away) would be 37 to 42 dBA for the 9 m/sec wind speed case, at and above which the wind turbine generators are expected to produce the most noise. With averaged measured existing sound levels reasonably representing ambient noise levels at these nearest noise-sensitive receivers, the cumulative increase over ambient for most operating cases would remain below applicable thresholds, and less than or equal to 5 dBA, and would result in no need for operation noise mitigation.
Risk of Fire or Explosion

The construction manager would be responsible for staying abreast of fire conditions in the project area by contacting WDNR and implementing any necessary fire precautions. A Fire Protection and Prevention Plan would be developed for EFSEC approval and implemented, in coordination with the Skamania County Fire Marshall and appropriate agencies. The following chart lists sources of potential fire and explosion along with measures to mitigate the risk of either occurring.

Fire and Explosion Risk Mitigation Plan

<table>
<thead>
<tr>
<th>C / O</th>
<th>Potential Fire or Explosion Source</th>
<th>Mitigation Measures</th>
</tr>
</thead>
</table>
| C & O | General Fire Protection           | • All on-site service vehicles fitted with fire extinguishers  
|       |                                   | • Fire station boxes with shovels, water tank sprayers, etc. installed at multiple locations on site along roadways during summer fire season  
|       |                                   | • Minimum of one water truck with sprayers must be present on each turbine string road with construction activities during fire season |
| C & O | Dry vegetation in contact with hot exhaust catalytic converters under vehicles | • No gas powered vehicles allowed outside of graveled areas  
|       |                                   | • Mainly diesel vehicles (i.e. w/o catalytic converters) used on site  
|       |                                   | • Use of high clearance vehicles on site if used off-road |
| C & O | Smoking                           | • Restricted to designated areas (outdoor gravel covered areas) |
| C & O | Explosives used during blasting for excavation work | • Only state licensed explosive specialist contractors are allowed to perform this work – explosives require special detonation equipment with safety lockouts  
|       |                                   | • Clear vegetation from the general footprint area surrounding the excavation zone to be blasted  
|       |                                   | • Standby water spray trucks and fire suppression equipment to be present during blasting activities |
| C & O | Electrical Fires                  | • Use of generally high clearance vehicles on site  
|       |                                   | • No gas powered vehicles allowed outside of graveled areas  
|       |                                   | • All major construction equipment used is to be diesel powered (i.e. w/o catalytic converters) |
| C & O | Lightning                         | • Specially engineered lightning protection and grounding systems used at wind turbines and at substation  
|       |                                   | • Footprint areas around turbines and substation are graveled with no vegetation |
| C     | Portable Generators – hot exhaust | • Generators not allowed to operate on open grass areas  
|       |                                   | • All portable generators to be fitted with spark arrestors on exhaust system |
| C     | Torches or field welding on-site   | • Immediate surrounding area would be wetted with water sprayer  
|       |                                   | • Fire suppression equipment to be present at location of welder/torch activity |
| C & O | Electrical Arcing                 | • Electrical designs and construction specifications meet or exceed requirements of the National Electric Code and National Fire Protection Agency |

a. Indicated risk during construction (C) and/or operations (O)

Lightning-induced fires are rare in the project area and both the wind turbine generators and the substation are equipped with specially engineered lightning protection systems. With the types of modern wind turbines proposed for the project, however, turbine malfunctions leading to fires in the nacelle are extremely rare. The turbine control system detects overheating in turbine machinery, and internal fires would be detected by these sensors, causing the machine to shut down immediately and send an alarm signal to the central SCADA system, which would notify operators of the alarm by cell phone or pager.

The potential fire risks are similar in nature but lower for project decommissioning. Fire prevention measures during decommissioning would be similar to those for project construction.
1.4.1.9 Section 4.2, Land and Shoreline Use

Land Use

No impacts to land use are anticipated, and no mitigation measures are required.

Light and Glare

Mitigation measures for light and glare would be as follows:

- Most construction would occur during daylight hours, minimizing construction lighting at during hours of darkness
- Turbines and blades would be painted with a non-reflective gray finish to blend in with the background, and to eliminate the need for white daytime aviation warning lights
- To prevent glare, non-reflective earth-tone/light paint colors would be used on exterior surfaces of buildings or other facilities
- The facility lights outside the Operations and Maintenance area and the substation sites would be hooded and directed downward to minimize backscatter and illumination of off-site areas
- Lights would be the minimum wattage required for safety
- Sensors and switches would be used to keep lights turned off when lighting is not required

Aesthetics

Because the turbines are most frequently seen against the sky, particularly in close-range views where visual concerns are the greatest, a non-reflective flat neutral gray or light color is recommended to minimize aesthetic impacts.

Recreation

Impacts to recreation users during the construction phase would primarily result from dust and noise from construction equipment. While the project would not affect any trails or pathways in the Scenic Area, there may be some distant views of wind turbines from trails during operations. Because they are high on the ridge, no mitigation measures are proposed other than painting the turbines a flat gray.

Historic and Cultural Preservation

Because no cultural resources (archaeological sites or historic properties) were identified in the project area, no mitigation actions are required. If cultural resources are inadvertently discovered during project construction and operations, assessment of the find would be
necessary. If such cultural resources are found to be significant, mitigation measures would need to be devised and implemented.

**Agricultural Crops/Animals**

There would be no impacts to agricultural crops and animals, therefore mitigation measures are not proposed.

**1.4.1.10 Section 4.3, Transportation**

**Construction Traffic Control**

The following mitigation measures are proposed to reduce impacts from project construction on roadway traffic in the region:

- A Transportation Management Plan (TMP) would be prepared in consultation with both WSDOT and Skamania County and submitted to EFSEC for approval that would direct and obligate the contractor to implement procedures to minimize traffic impacts
- The TMP would include requirements for coordination of project-related construction traffic and WSDOT planned construction projects
- The TMP would include requirements for coordination of project-related construction traffic and Skamania County, City of Bingen, and City of White Salmon summer recreational traffic
- Whistling Ridge Energy LLC and its contractors would be required to comply with State and County permitting requirements for over-size and over-weight vehicles
- Whistling Ridge Energy LLC would be required to notify land owners in the project vicinity prior to construction of transportation routes that would be used for construction equipment and labor
- Approved State and/or County advanced warning construction signs would be placed prior to and during construction
- Certified flaggers would be used when necessary to direct traffic when over-size and over-weight trucks either enter or exit public roads, to minimize risk of accidents
- Pilot cars would be used both in front of and behind all trucks transporting over-size or over-weight loads on all public roadways
- Traffic flow would not be restricted for more than 20 minutes during the construction phase
Access Roadway Construction

All sections of the access roadway system that would require improvements or new construction would be designed and built according to WSDOT and Washington State access management standards.

Hazardous Materials Transport

Transport of hazardous materials would be conducted in a manner that would protect both human health and the environment and would be in accordance with applicable Federal and WSDOT requirements.

Roadway Maintenance

- Pre- and post-haul construction visual assessments of roadway surface conditions would be conducted identifying weak or deteriorated areas along the haul route that may require mitigation
- Should mitigation be required, a mitigation design program would be developed to repair all pavement sections to pre-construction conditions or better
- Whistling Ridge Energy LLC would be responsible for maintaining turbine string access roads, access ways, and other roads built to construct and operate the proposed project
- All snow removal would be performed in a safe manner that would not degrade roadway conditions

1.4.1.11 Section 4.4, Socioeconomic Impact

Socioeconomic impacts are expected to be beneficial in the form of additional jobs, increased sales, and increased tax revenues. Temporary increases in population due to worker relocation during construction are likely to be less than significant in view of the availability of housing, transient accommodations, and other public services in the region. Specific mitigation measures to lessen the impacts of the construction phase on public service providers in the Whistling Ridge Energy Project vicinity include:

- Construction activities would be coordinated with local police and fire departments, as well as emergency medical service providers, to ensure access to all locations in the project site vicinity in the case of an emergency.
- To help mitigate loss of access and other traffic-related impacts, adequate traffic control and signage, indicating closures and alternate routes, would be provided where needed.
• Construction vehicle trips in and out of the immediate construction zone would be coordinated and scheduled away from peak travel periods as much as possible, to minimize general traffic disruption.

• Noise and dust problems generated by construction would be mitigated through the use of properly muffled construction equipment, and by the use of approved dust control methods.

For related discussions of impacts and mitigation, see Section 3.2 Air, Section 4.1 Environmental Health, and Section 4.3 Transportation.

1.4.2 FAIR TREATMENT

No social or environmental justice impacts are anticipated to result from the construction and operation of the Whistling Ridge Energy Project. There will be no land use displacements or relocations as a result of project, nor will the developed area for the project extend beyond the private forestry land owned by S.D.S. Co., LLC and Broughton Lumber Companies. The construction and operation of the project is not predicted to result in potential disproportionately high and adverse effects to minority or low income populations.

The project would not displace any minority or low-income populations. The project would be constructed on private land not occupied by residents or businesses owned by anyone other than the Applicant. As discussed in Section 4.4.1.1, the area near the project does not have a substantially higher minority or low-income population when compared to larger reference populations. Section 4.1, Environmental Health, states that infrasound (noise) potential impacts are considered to be either non-existent or less than significant during operation. Permanent visual changes due to project operation would be low to moderate. Therefore, this analysis finds that high and disproportionate impacts upon minority and low-income populations would not occur.

The demographics of the project study area have been identified and a public involvement effort undertaken to reach all of the surrounding residents, including minority and low-income populations.

The overall population and minority population data for year 2008 for Skamania County are shown in Table 1.4-1, followed by Table 1.4-2 showing population living under the poverty level.

The race and ethnicity composition of the project area is estimated by analyzing the three census block groups that most closely match an area defined by a three-mile radius around the project site. When combined, the population in these three census blocks is approximately 12 percent minority. The second most common race and ethnicity category for residents in this area is (1) Hispanic/Latino, and (2) Some Other Race or Two or More Races.

The population living within three miles of the project site has a lower minority percentage than the two nearest cities (White Salmon and Hood River), Klickitat County, Hood River County, Washington State, and Oregon State. The population within three miles of the project site has a
higher minority percentage (12 percent) compared to the same measure for Skamania County as a whole (11 percent). Although minority residents do exist near the project site, the area near the project does not have a substantially higher minority population when compared to larger reference populations.

Source: Claritas (2009).

For the purpose of this analysis, minority includes those residents identified as Black or African American, American Indian or Alaskan Native, Asian Pacific Islander, Some Other Race, Two or More Races, or Hispanic/Latino.

Percentages may not total 100 percent due to decimal places not expressed in this table.

AIAN = American Indian or Alaskan Native
API = Asian Pacific Islander
B = Black
CBG = Census Block Group
CT = Census Tract
SOR = Some Other Race or Two or More Races
W = White

Poverty status in 2000 is available for all areas studied. More current poverty statistics (for the period 2005 to 2007 as an annual average) are only available for the areas with relatively larger populations (Klickitat County, Hood River County, Washington, and Oregon). Table 1.4-2 shows 2000 poverty statistics for all areas (for comparison purposes), and also shows more current poverty statistics where available. Poverty estimates for 2008 were not available.

In 2000, 17 percent of the populations of the cities of White Salmon and Hood River were living below the poverty level. This same measure was 13 percent for Skamania County, 17 percent for Klickitat County, and 14 percent for Hood River County the same year. The cities and counties near the project site had relatively more residents living below the poverty level compared to Washington as a whole, and Oregon as a whole in 2000.

Approximately nine percent of the population living within approximately three miles of the project site lived below the poverty level in 2000, indicating fewer people living in poverty compared to the cities and counties near the project site. The geographic areas for which more recent (2005–2007 annual average) poverty statistics are available have all increased in percentage of persons living below the poverty level, as shown in Table 1.4-2.

</tbody>
</table>

a. Estimates of this type of data for the areas with smaller populations (census block groups, cities, and Skamania County) were not available for more recent years from the US Census or from Claritas.

b. Poverty status was determined by dividing the population living below poverty by the population for whom poverty status is determined, which excludes those living in institutional housing.

Operation of the project would result in a positive economic impact to Skamania County and the state due to increased tax revenues, employment, and local expenditures. Operation of the project would require 8 to 9 full-time employees. These new jobs will increase the opportunities for all Skamania County residents, including minority and low-income populations.

SECTION 2.1 SITE DESCRIPTION
(WAC 463-60-125)

2.1.1 LOCATION OF WHISTLING RIDGE ENERGY PROJECT

The proposed Whistling Ridge Energy Project would be located on private land located approximately 7 miles northwest of the City of White Salmon in Skamania County, Washington (Figure 2.1-1, Location of Proposed Whistling Ridge Energy Project). The project would be located on commercial forestland owned by S.D.S. Co., LLC and Broughton Lumber Company in an unincorporated area of Skamania County, outside of the Columbia Gorge National Scenic Area.

The project site encompasses approximately 1,152 acres in Sections 5, 6, 7, 8, and 18 of Township 3 North, Range 10 East, and in Section 13 of Township 3 North, Range 9 East.

The Applicant seeks approval of construction of wind turbine generators, roads, and electrical collection cables and transmission lines within corridors that will be described and analyzed in the environmental impact statement (EIS). Actual final locations of wind turbine generators and other related and supporting facilities would be established during the micrositing process. During the micrositing process (when the final, exact locations of the turbines and other project elements and equipment are determined), the Applicant must balance a number of technical and engineering factors, including limitations posed by the terrain, wind data (speed, wind sheer, etc.), wake effects of turbines, location of roadways and transportation systems, and feasibility of access, setbacks (internally established or permit requirements), geotechnical considerations (subsurface conditions), environmental restrictions (avoidance of sensitive habitat), cultural/archeological restrictions (avoidance of cultural resource sites), telecommunications constraints (line of sight microwave paths), Federal Aviation Administration (FAA) lighting requirements, and other site-specific criteria that are not fully resolved until final engineering is completed.

Access to the project area is provided by county and private logging roads that extend north from State Route (SR) 14. From SR 14, access would be provided via County roads (Cook-Underwood Road to Kollack-Knapp-Willard Road onto Scoggins Road) and then via a new connection direct to West Pit Road, an existing private logging road. West Pit Road connects and then to a network of existing private logging roads. The private logging roads are on S.D.S. Co., LLC and Broughton Lumber Company property, and provide access to most areas where project facilities would be located.
As shown on Table 2.1-1, approximately 384 acres would be developed for the wind turbine foundations, connecting roadways, and overhead and underground transmission lines.

a. Project site is the area shown on Figure 2.1-1 bordered in black, encompassing approximately 1,152 acres in Sections 5, 6, 7, 8, and 18 of Township 3 North, Range 10 East, and in Section 13 of Township 3 North, Range 9 East.
b. Windfarm footprint is the total area of all corridors and development study areas in the project boundary with overlapping areas removed, in which development potentially will take place.
c. Total area of 650-foot corridor measured on either side of an imaginary line connecting each turbine in a string. Permanent impacts based on turbine clearance zone and permanent infrastructure in corridor but outside of clearance zone. Temporary impacts based on infrastructure in corridor but outside clearance zone, as described in Section 2.3 and shown on Figure 2.3-4.
d. Area encompassed by a 100-foot corridor along all roads within the project area minus any area that overlaps with 650-foot-wide turbine corridor, based on a roadway length of 7.5 miles.
e. Total area encompassed by a 200-foot corridor on the overhead transmission lines minus any area that overlaps with roadway or turbine string corridors.
f. Total area encompassed by a 100-foot corridor on the overhead or underground transmission lines minus any area that overlaps with roadway, overhead or turbine string corridors.
g. Area includes the 2-acre Operations and Maintenance site plus a 50-foot area around the perimeter.
h. Area includes the 5-acre substation site plus a 50-foot area around the perimeter.
i. Area based on 40-foot corridor (20-foot roadway; 12-foot existing, widened to 20 feet with 10 feet on either side) from project site boundary to intersection of Scoggins and CG2930 an intersect point with Willard Road, based on a length of 2.12.5 miles.

Because the project site already has a network of logging roads, relatively few new roads would have to be constructed. Approximately 27.9 miles of existing private logging roads located on land owned by SDS Co., LLC and Broughton Lumber Company would be improved. In areas where there are no existing logging roads near proposed wind turbine strings, approximately 2.4 miles of new gravel access roads would be constructed. All of these construction roads would continue to be used during the project’s operational phase.

Of the total 610.3 miles of access roads, approximately 57.8 miles would be located within the project area. The remaining approximately 42.5 miles would be located outside of the
project area within and outside of the Columbia River Gorge National Scenic Area. All new road construction would occur within the project area (Table 2.1-2).

Existing logging roads are constructed, and are regularly improved and maintained to enable large trucks and logging equipment to access the project site for ongoing commercial logging purposes. These roads are generally 8 to 12 feet wide, although some are currently as wide as 20 feet. Improvements to allow use by construction vehicles generally would involve widening and providing a gravel all-weather surface. Most of the roads used to provide access to the site by construction vehicles would be widened to approximately 25 feet (width of finished road), with an additional 5 feet of shoulder on either side.

The project proponent has requested to integrate power from the Whistling Ridge Energy Project into the Federal Columbia River Transmission System (FCRTS) that exists within the project area.

2.1.2 PROMINENT GEOGRAPHIC FEATURES

The project site is located on a series of north-trending ridges that range in elevation from approximately 2,100 to 2,300 feet above mean sea level (msl). The land west of the proposed project site drops sharply to a narrow river terrace and then to an elevation of less than 800 feet above msl in the Little White Salmon River valley. The topography northeast of the site drops gradually toward the White Salmon River or climbs gently up the northeast flank of Underwood Mountain (2,728 feet above msl). To the south, the topography drops to a terrace of largely agricultural use, then toward the Columbia River.

2.1.3 TYPICAL GEOLOGICAL AND CLIMATOLOGICAL CHARACTERISTICS

The following summarizes the geological and climatological characteristics of the site. For a more complete discussion of site geology, please see Section 3.1, Earth.

2.1.3.1 Geology

The White Salmon, Washington area is located within the Cascade Range and the Columbia Intermontane Physiographic Province. The project area is located just within the western boundary of the Columbia Plateau, which is located at the western edge of the Columbia Intermontane Physiographic Province (Freeman et al. 1945). This lowland province is surrounded on all sides by mountain ranges and highlands, and covers a vast area of eastern Washington and parts of northeastern Oregon and western Idaho.
A variety of younger volcanic rocks and sedimentary materials that range from Pliocene (1.8 to 5.3 million years before the present [BP]) to Holocene (less than 10,000 years BP in age) overlie the Columbia River Basalt Group (CRBG) in the project area. Sedimentary rocks are generally thought to underlie the basalts in the project area.

The proposed project site is located within the northern boundary of the structural Hood River Valley, which extends a few miles into southern Washington. In general, the geology of the area consists of basalt flows extruded from local vents, layer with conglomerate, tuff, tuff breccias, and other volcanoclastic deposits. These formations are typically overlain by silt and clay soil of varying thickness in the project vicinity. The bedrock underlying the proposed project site consists of Grande Ronde Basalt of the CRBG and Quaternary basalt of Underwood Mountain—a shield volcano that lies approximately midway between the lower reaches of the Little White Salmon and White Salmon Rivers. Its southern slopes drain to the Columbia River.

No faults are mapped within the footprint of the proposed Whistling Ridge Energy Project area. However, faults are mapped approximately 1.5 miles southwest and northeast of the proposed project area. Many of these faults are inferred and shown as dotted lines buried by younger surficial deposits. The activity of the area faults is unknown. However, a review of aerial photography shows no indication of recent movement along the trace of the inferred faults.

During the current subsurface exploration, groundwater was not encountered in the site up to a depth of 16 feet below ground surface (bgs). It should be noted that these observations reflect groundwater levels at the time of the field investigation. Actual groundwater levels may fluctuate significantly in response to seasonal effects, regional rainfall, and other factors not observed during this investigation. There may be regional or perched water tables at greater depth. Prior to final design of the tower foundations, additional subsurface investigations (boreholes) would be required to provide geotechnical data at foundation and anchor depths. Future deep foundation investigations will include observation of groundwater, if encountered.

2.1.3.2 Climate

Skamania County’s location, sheltered by the Cascade Mountains in the Columbia River Gorge, provides for a moderating climate between the storms rolling in from the Pacific Ocean and the extreme seasonal temperature shifts that occur in eastern Washington. Winters may be near freezing, depending on location, while summers are usually mild. Frequent strong winds and precipitation dominate the weather pattern within the Gorge throughout the year (Haagen 1990).

Temperature and precipitation data was recorded at Wind River, Washington and Bonneville, Oregon from 1951 to 1978 (Haagen 1990). Wind River is at about 1,100 feet above msl and about 15 miles northwest of the Whistling Ridge Energy Project site. Bonneville, Oregon is situated around 80 feet above msl and lies about 19 miles southwest of the project site. Average winter temperatures were 38 and 39 degrees Fahrenheit (°F), respectively, with average daily minimums of 33 and 28°F. The average summer temperatures are 63°F (Wind River, WA) and 65°F (Bonneville, OR) with an average daily maximum of 76°F.
Carson Fish Hatchery, located at 1,130 feet above msl and about 19 miles northwest of the project site, recorded slightly cooler winter and similar summer temperatures from 1977 to 2000 (USDA NRCS 2008). Average December and February temperatures settled around 34°F with average daily minimums around 28°F. Summer temperatures averaged 61°F with daily maximums averaging 80°F.

The average total annual precipitation from 1951 through 1978 is 77 inches at Bonneville, Oregon and 102 inches at Wind River, Washington. Twenty percent of the total precipitation for both areas falls between April and September. The average seasonal snowfalls are 13 and 109 inches, respectively (Haagen 1990). Carson Fish Hatchery received an average annual total precipitation of 88 inches from 1977 through 2000. Average seasonal snowfall during the same period at the fish hatchery totaled 77 inches (USDA NRCS 2008).

The prevailing winds though the Columbia Gorge shift seasonally. Gale force winds are not uncommon. Westerly winds prevail during the summer months. Cold easterly winds usually blow through the Gorge during winter months. These winter winds occasionally collide with the moist Pacific air masses leading to severe ice storms, locally described as silver thaws (Haagen 1990).

Wind power and wind speed maps published by the Northwestern U.S. Wind Mapping Project and verified by the U.S. Department of Energy’s National Renewable Energy Laboratory identify the ridge line where the Whistling Ridge Energy Project would be constructed as a viable wind energy resource. Models indicate that winds passing 50 meters above the ground surface in this vicinity reach sustained speeds of between 15.7 and 17.9 miles per hour depending upon location (NWSEED 2002a). Such wind speeds rate this area as wind power potential of good (Class 4) to Outstanding (Class 5) (NWSEED 2002b). One concentrated area within the project area is identified as having outstanding (Class 6) wind power potential with sustained wind speeds of 17.9 to 19.7 miles per hour.

2.1.4 LAND USE PLANS AND ZONING ORDINANCES

A description of the applicable comprehensive plans, zoning, and development regulations and other land use programs relevant to the Whistling Ridge Energy Project is included in Section 4.2.1, Land Use.

The site is located entirely within unincorporated areas of Skamania County. Portions of the land are designated as Conservancy in the Skamania County Comprehensive Plan. The majority of the land is currently zoned as Unmapped, except for a small part of the southwest portion of the project area where seven turbines are proposed, and the alternative site for the maintenance and operations facility located along West Pit Road. Pursuant to the locally adopted land use plans and ordinances in effect at the time of this application, wind energy facilities are an outright permitted use in the Unmapped (UNM) area of the project. In the southwest portion of the property where approximately seven proposed turbines would be located, approximately three to four turbines would be located on the property is zoned Resource Protection (For/Ag-20) and three to four turbines would be located on property zoned Residential 10, a transitional zone. The site proposed for the alternative Operations and Maintenance facility along West Pit Road, to the west of the project site,
is on land zoned Residential 5. A conditional use permit would be required only for these two areas of the project.

Skamania County is in the process of considering amendments to its zoning code. In the current draft ordinance, the entire project area is proposed for Forest Land 20 (FL-20) zoning. This proposed zoning code amendment is being challenged by a variety of parties, including a pending appeal of the County’s State Environmental Policy Act (SEPA) determination related to the proposed zoning code. Under the proposed FL-20 zoning, the code would allow “Large-Scale Wind Energy Facilities,” subject to conditional use approval.
SECTION 2.2 LEGAL DESCRIPTIONS AND OWNERSHIP INTERESTS
(WAC 463-60-135)

2.2.1 INTRODUCTION

The proposed Whistling Ridge Energy Project would be located on private land approximately 7 miles northwest of the City of White Salmon in Skamania County, Washington. The project would be located on commercial forestland owned by S.D.S. Co., LLC and Broughton Lumber Company in an unincorporated area of Skamania County, outside of the Columbia River Gorge National Scenic Area.

An alternative site is proposed for a maintenance and operations facility, located outside of and to the west of the project site along West Pit Road. This land is owned by the Broughton Lumber Company.

Whistling Ridge Energy LLC, a special purpose corporation operating in the State of Washington, is developing and would own the project.

The total project area encompasses approximately 1,152 acres in Sections 5, 6, 7, 8, and 18 of Township 3 North, Range 10 East, and in Section 13 of Township 3 North, Range 9 East.

The alternative operations and maintenance yard along West Pit Road would encompass approximately 5 acres in Section 1 of Township 3 North, Range 9 East.

2.2.2 LEGAL DESCRIPTION OF PROPERTY

Real property situated in the County of Skamania, State of Washington, hereby described as follows:

Township 3 North, Range 10 East of the Willamette Meridian:

Section 5: The West Half of the Southwest Quarter.
Section 6: All except for the West Half of the Southwest Quarter.
Section 7: The South Half of the Southwest Quarter, the Northeast Quarter of the Southwest Quarter, the West Half of the Southeast Quarter, the East Half of the Northwest Quarter and the Northeast Quarter excluding lands within the Columbia River Gorge National Scenic Area
Section 8: The West Half of the Northwest Quarter excluding lands within the Columbia River Gorge National Scenic Area
Section 18: The Northwest Quarter, and the Northwest Quarter of the Southwest Quarter excluding lands within the Columbia River Gorge National Scenic Area

Township 3 North, Range 9 East of the Willamette Meridian:

Section 13: The East Half of the Southeast Quarter excluding lands within the Columbia River Gorge National Scenic Area.
2.2.3 LEGAL DESCRIPTION OF ALTERNATIVE MAINTENANCE AND OPERATION FACILITY

Township 3 North, Range 9 East of the Willamette Meridian:

Section 1: Portions of The Southeast Quarter of the Southeast Quarter, and the Southwest Quarter
SECTION 2.3 CONSTRUCTION ON SITE  
(WAC 463-60-145)

2.3.1 WHISTLING RIDGE ENERGY PROJECT SUMMARY

The Whistling Ridge Energy Project would be constructed in south-central Washington on an approximately 1,152-acre site approximately 7 miles northwest of the City of White Salmon in Skamania County, Washington. The project would be located on commercial forestland owned by S.D.S. Co., LLC and Broughton Lumber Company in an unincorporated area of Skamania County, outside of the Columbia River Gorge National Scenic Area. See Figure 2.1-1, Location of Proposed Whistling Ridge Energy Project.

Turbines would be located on the forested ridges of Saddleback Mountain. The final locations of wind turbine generators and other related and supporting facilities would be established during the final design process (see Section 2.1, Site Description for more information).

The planned facility would have an installed capacity of up to 75 megawatts (MW) of electricity.

2.3.2 PROJECT OVERVIEW

The planned facility is shown on Figure 2.3-1, and would have:

- An installed capacity of up to 75 MW of electricity
- Up to fifty 1.2- to 2.5-MW wind turbines
- Electrical transformers
- 34.5 kilovolt (kV) collector lines and systems (primarily underground)
- Permanent meteorological towers
- Two alternative locations for an Operations and Maintenance facility
- A substation located adjacent to BPA’s existing North Bonneville to Midway 230-kV transmission line
- Approximately 2.4 miles of newly-constructed and 7.9 miles of improved roads to provide access to the wind turbine locations during construction and for Operations and Maintenance

The project substation would be built on the project site adjacent to BPA’s North Bonneville to Midway 230-kV transmission line, facilitating interconnection with the BPA grid. The proposed electrical interconnection to BPA would provide the access to the regional transmission grid for sales to the wholesale electric market. The development of the proposed interconnection requires a federal action, limited exclusively to the interconnection with the BPA grid.
Proposed Project Elements

Whistling Ridge Energy Project
Skamania County, Washington

Source: GeoDataScape.

Job No. 33758687

Revised Figure 2.3-1
The construction phase is anticipated to last approximately one year, during which a total of approximately 330 workers would be employed. Eight to nine permanent full- or part-time Operations and Maintenance staff would be required once the project is operational. See Section 2.12, Construction and Operation Activities for more information.

The Whistling Ridge Energy Project is expected to function for at least 30 years.

2.3.3 PROJECT COMPONENTS

2.3.3.1 Wind Turbines

The project would consist of up to 50 wind turbines. Because of the heightened activity in the wind energy industry, pricing and availability of turbines are highly variable. Consequently, the specific turbine type and manufacturer has not been selected. However, it is likely that the turbines would be in the 1.2- to 2.5-MW range, and the range of key parameters (such as turbine height and diameter) can be anticipated, even if the turbine manufacturer is not yet known.

Each turbine would be up to approximately 426 feet tall (262-foot hub height and 164-foot radius blades, measured from the ground to the turbine blade tip), and would be mounted on a concrete foundation. Wind turbines would be grouped in “strings,” each spaced approximately 350 to 800 feet from the next (or approximately 1.5 to 2.5 times the diameter of the turbine rotor). The electrical output of each string would be connected to the project substation by underground 34.5-kV collector cables, and from there would be directly interconnected with the adjacent BPA transmission system. The project would be monitored and controlled from an Operations and Maintenance building centrally located on the project site.

Wind turbines consist of four main aboveground components: the turbine tower (described below), the nacelle, the rotor hub, and the blades. The nacelle is encased in fiberglass, and is mounted at the top of the tower to house the gearbox, the generator, and the control system. The rotor hub is attached to the nacelle, and holds the blades in place. Each turbine has three laminated fiberglass blades, each approximately 129 to 164 feet long, depending on which turbine is selected. The diameter of the circle swept by the rotors would be approximately 264 to 320 feet, depending on which turbine is selected. Together, each turbine’s blades, hub, and nacelle would weigh between 95 and 150 tons, depending on the turbine size and model selected.

The wind turbines would operate at wind speeds from 9 to 56 miles per hour (mph), with a rotor speed range of 10 to 20 revolutions per minute (rpm). The turbines operate on a variable pitch principal in which the rotor blades rotate to keep them at the optimum angle to maximize output for all wind speeds. At speeds exceeding 56 mph, the blades feather on their axis and the rotor stops turning. Each turbine is equipped with a wind vane that signals wind direction changes to the turbine’s electronic controller. The electronic controller operates electric motors (the yaw mechanism), which turn the nacelle and rotor so that each turbine faces into the wind.
2.3.3.2 Turbine Towers

Depending on which manufacturer is selected, each turbine would be approximately 221 to 262 feet tall at the turbine hub, and with the nacelle and blades mounted, the total height of each wind turbine (to the turbine blade tip) would be up to approximately 426 feet. The towers would be tapered, hollow tubular structures, approximately 14 feet in diameter at the base and weighing approximately 30 tons each. The towers would likely be painted a flat neutral gray or white color. A controller cabinet would be located at the base inside each tower. Cables and a ladder would ascend to the nacelle to provide access for turbine maintenance. A locked door would provide access to the base of the tower. Some of the towers would be furnished with blinking lights visible to aircraft. The need for turbine lights and the type of lighting would be determined in consultation with the FAA.

Each tower would be mounted on a concrete foundation with a diameter up to approximately 60 feet. Tower foundations would be spread footing or pier-type footings.

2.3.3.3 Electrical System

The project’s electrical system would consist of two key elements: (1) a collector system, which would collect energy generated at approximately 575 volts from each wind turbine, transform the voltage to 34.5 kV using a pad-mounted transformer, and deliver the energy via underground cables to (2) the project substation, which would further transform the energy delivered by the underground collector system from 34.5 kV to 230 kV and deliver it to the adjacent BPA transmission line and into the regional transmission system.

2.3.3.4 Collector System

Each turbine’s 575V/34.5kV transformer adjacent to each tower would be located on a transformer pad, or enclosed in the nacelle, depending on the turbine model. If required, the transformer pad would be approximately 9 feet by 9 feet square and 12 inches thick, constructed approximately 5 feet away from the tower pad. From there, power would be transmitted via underground 34.5-kV electric cables, buried directly in the soil approximately 3 to 4 feet bgs, in a trench up to 5 feet wide. In areas where collector cables from several strings of turbines follow the same alignment (for example, near the substation), multiple sets of cables would be installed within each trench where possible. A disturbed area approximately 30 feet in width is anticipated; however, impacts would be temporary, and the areas outside of roadways would be revegetated after the cable installation is completed. There would be approximately 8.5 miles of underground collector cable trenches. In areas where environmental constraints, geologic features, or cultural features necessitate, minor aboveground placement of collector cables may occur.

2.3.3.5 Substation

The substation site would occupy a portion of a fenced 5-acre area at the southwest end of the project site, immediately adjacent to the BPA 230-kV transmission line. A 50-foot cleared area would be maintained around substation. The substation site would be a graveled, fenced area
with transformer and switching equipment and an area to park utility vehicles. Transformers would be non-polychlorinated biphenyl oil-filled types.

2.3.3.6 Operations and Maintenance Facility

A permanent Operations and Maintenance facility would be constructed on an approximately 25-acre area located at one of the following two alternative locations: (1) adjacent to the substation; or (2) to the west of the project site along West Pit Road. It would have approximately 3,000 square feet of enclosed space, including office and workshop areas, a kitchen, bathroom, shower, and utility sink. It would be constructed of sheet metal, and would be approximately 16 feet tall (to the roof peak). Water for the bathroom and kitchen would come from a new on-site well. Water use would be less than 5,000 gallons per day. The bathroom and kitchen would drain into an on-site septic system. A graveled parking area for employees, visitors, and equipment would be located adjacent to the building. The entire area would be fenced and have a locked gate.

2.3.3.7 Access Roads

Access to the project site is provided by county and private logging roads that extend north from State Highway 14. From Highway 14, access would be provided via County roads (Cook-Underwood Road to Kollack-Knapp-Willard Road onto Scoggins Road) and then via a new connection to West Pit Road, an existing private logging road. West Pit Road connects to a network of existing private logging roads (Figure 2.3-1, Proposed Project Elements). The private logging roads are on S.D.S. Co., LLC and Broughton Lumber Company property, and provide access to most areas where project facilities would be located.

Because the project site already has a network of logging roads, relatively few new roads would have to be constructed. Approximately 7.2-7.9 miles of existing private logging roads would be improved. In areas where there are no existing logging roads near proposed wind turbine strings, approximately 2.4 miles of new gravel access roads would be constructed. All new roadway construction would occur on private lands owned by S.D.S. Co., LLC and Broughton Lumber Company. Approximately 2.4-2.5 miles of roadway improvements would occur on West Pit Road, a gravel-dirt road covered in light pit run, that connects the project site via Willard Road to the Cook-Underwood Road. West Pit Road is located entirely outside of traversing the Columbia River Gorge National Scenic Area. West Pit Road currently varies in width between 20 and 26 feet. To create a drivable surface of 25 feet with 5 feet of of clearing on each side, some widening would be required for the roadway, the existing culvert and some corners. Some of these construction roads West Pit Road would continue to be used during the project’s operational phase.

Existing logging roads were originally built to enable large trucks and logging equipment to access the project site for ongoing commercial logging purposes. These roads are generally 8 to 12 feet wide, although some are currently as wide as 20 feet. Improvements to allow use by construction vehicles generally would involve widening and providing a gravel all-weather surface. Most of the roads used to provide access to the site by construction vehicles would be widened to approximately 25 feet (width of finished road), with an additional 5 feet of shoulder on either side.
Once assembled, the construction cranes required to erect turbine and tower sections require a 40-foot-wide road (of which 25 feet needs to be graveled). Therefore, the roads that run adjacent to turbine strings and roads that connect turbine strings to a central staging area would be approximately 35 feet wide (25 feet plus 5 feet of shoulder on either side). Because cranes might be needed to maintain turbines over their operational life, the 35-foot-wide roads would be kept as maintenance access roads for the expected 30-year life of the project.

All private roadway improvements required prior to hauling and new private roadway construction at the proposed project site would be designed and constructed under the direction of a licensed engineer, in accordance with the standards for the applicable road classifications as set forth in the Skamania County Private Road Guidelines and Development Assistance Manual, as adopted by the County Resolution in 2008. All existing county roadways requiring improvements prior to hauling would be designed and constructed in accordance with the WSDOT Design Manual (WSDOT 2007) and A Policy on Geometric Design of Highways and Streets (AASHTO 2004). A gravel surface would be installed, compacted to meet all equipment load requirements, and maintained to reduce wind erosion and dust. Existing culverts across intermittent streams would be replaced with wider or stronger culverts as necessary, and drainage improvements would be made (pursuant to a Project Erosion Control Plan and National Pollutant Discharge Elimination System [NPDES] permit) as necessary to control runoff.

In addition to the permanent access roads described above, temporary access may be required for constructing some facilities. For example, constructing the underground collector cables would require that heavy equipment be able to access trench locations where they are not directly adjacent to roads. Generally, equipment would be driven across open ground to accomplish this construction; in some locations minor grading may be required to allow safe access to construction locations (that would be determined only after final pole locations have been selected). These temporary access roads would be regraded and reseeded as necessary to restore vegetation after the construction phase is over.

After the project is constructed, use of the improved and new access roads on private lands would be limited to the landowner and to project maintenance staff.

2.3.4 TRANSMISSION INTERCONNECTION

Power generation resources typically require interconnection with a high-voltage electrical transmission system for delivery to purchasing retail utilities. BPA owns and operates the FCRTS, which includes more than three-fourths of the high-voltage transmission grid in the Pacific Northwest and includes extra-regional transmission facilities. BPA operates the FCRTS, in part, to integrate and transmit “electric power from existing or additional Federal or non-Federal generating units” (16 United States Code [USC] 838b). Interconnection with the FCRTS is essential to deliver power from many generation facilities to loads both within and outside the Pacific Northwest.

In summary, electrical consumers served by the Northwest Power Pool and in other western states need increased power production to serve increasing demand, and high-voltage transmission services to deliver that power. The project proponent has requested to integrate
power from the Whistling Ridge Energy Project into the FCRTS that exists within the project area.

### 2.3.5 CONSTRUCTION

Construction is expected to take approximately one year, and would likely occur from early spring through late fall. Construction of the project would involve the following tasks:

- Harvesting trees in areas that are not already cleared
- Constructing roads and turbine crane pads
- Constructing foundations for turbine and meteorological towers
- Trenching for underground utilities
- Placing underground electrical and communications cables in trenches
- Constructing the substation
- Constructing interconnections between the substation and the existing BPA transmission line
- Constructing the Operations and Maintenance building
- Transporting tower sections to the site and assembling towers
- Transporting nacelle, rotor, and other turbine equipment to the site and installing the equipment on the assembled towers
- Final testing
- Final road grading, final erosion control, and site cleanup

After the project has been constructed, trees on most of the site would be allowed to mature on a normal forest management schedule (according to the SDS Lumber Company staff, trees in the project area grow about 2 foot per year on average). Figure 2.3-2, Forest Management, shows the current forest types in the project area.

The exception would be in an area immediately surrounding the turbines and the access roads to the turbines. To allow for safe access to each tower for maintenance, to eliminate the potential for trees falling against the towers during storms, and for fire protection, an area extending approximately 150 feet from the center of each tower would be managed to maintain vegetation below approximately 15 feet in height. These dimensions may be adjusted during the final micrositing process to best balance the interest of maximizing electrical generation, along with maximizing replanting of all trees to ensure the best possible operation of the site for ongoing commercial forestry purposes.
2.3.6 FOREST HARVEST

The project site is on land managed for commercial forestry by S.D.S. Co., LLC and Broughton Lumber Company. All of the parcels on which the project is located are managed for a continual cycle of growth, harvest, and replanting. As a longstanding commercial forestry site, no old-growth forests exist in areas where the project is proposed. Many of the remaining stands of trees on the sections of land that would have turbines on them are near maturity and S.D.S. Co., LLC and Broughton Lumber Company implemented timber harvest plans on portions recently. Harvests have occurred in the project area over time, pursuant to long-established harvesting schedules (Figure 2.3-3, Harvesting Schedule).

Harvests have typically occurred approximately every 50 years; however, the harvest periods vary depending on the market and the demand for the type of timber. As a result, some harvests have occurred as frequently as 40 years, and some have been up to 65 to 70 years. Additional harvests are planned, subject to requirements of a Forest Practice Application.

In areas surrounding the proposed wind turbines that have not been recently harvested or that are not planned to be harvested before project construction, trees would be harvested and the land would be replanted with seedlings. This clearing would allow for safe construction, and would reduce the potential for tree growth to interfere with the wind resource on the site during the commercial life of the project (that is, during the 30-year commercial life of the project, trees that are planted at the time of construction in the cleared area would regrow at a rate that would not interfere with wind energy production). Typically, the cleared area would extend approximately 50 feet in all directions from each turbine. From a distance of approximately 50 feet to 150 feet from the base of the turbines, tree heights would be limited to a height of approximately 15 feet above the elevation of the base of the turbine. Extending from approximately 150 feet to 500 feet from the base of the turbines, there would be a restriction of approximately 50 feet in height above turbine foundation level for trees located within an area formed by a 90-degree angle centered on the prevailing wind direction and on the downwind side of the prevailing wind direction. Final locations and dimensions would be determined during the final design, micrositing and construction process (Figure 2.3-4, Turbine Timber Buffer).

In addition to the clearing around turbines, there would be an approximately 100-horizontal-foot limitation placed on trees along any overhead electrical cable corridors, or such standards as are determined by the project engineers in consultation with BPA or others, as applicable.

The permanently disturbed, cleared area described above would be considered a “forest conversion” under the Washington Forest Practices Act (WFPA) because it is being implemented for the purpose of the project. However, to the extent feasible for the project, cleared areas would be reforested in accordance with typical commercial forestry management practices.

Job No. 33758687

Whisting Ridge Energy Project
Skamania County, Washington
The areas where tree clearing is required would be clear-cut using crawler tractors, rubber-tired skidders, and mobile feller-bunchers, as has been done on other stands on the property. Logs would be transported by truck to SDS Lumber Company facilities in Bingen, Washington. Except for areas to be maintained and permanently cleared for the construction of permanent improvements and ongoing maintenance and operation access needs (which would be replanted with appropriate native grasses and low-growing shrubs), cleared areas would be replanted with trees within one year after completion of construction (note: tree planting is done in the spring of each year).

2.3.7 DECOMMISSIONING

For financial evaluation and contractual purposes, the Whistling Ridge Energy Project is expected to have a useful life of at least 30 years. The trend in the wind energy industry has been to “repower” older wind energy projects by upgrading equipment with more efficient turbines. It is likely that the project would be upgraded with more efficient equipment, and therefore have a useful life longer than 30 years. However, if the project were terminated, the necessary authorization from the appropriate regulatory agencies would be obtained to decommission the facilities. All aboveground facilities would be removed from the site, and unsalvageable material would be disposed of at authorized sites. To avoid unnecessary future ground disturbance and related environmental impacts, the turbine foundations would likely be removed to a depth of three to four feet bgs, and underground electrical cables would likely be abandoned in place. The soil surface would be restored as close as reasonably possible to its original condition. Reclamation procedures would be based on site-specific requirements and forest management techniques commonly employed at the time the area is to be reclaimed, and would include regrading, adding topsoil, and replanting of all disturbed areas. Decommissioned roads would be reclaimed or left in place based on landowner preference, and right of way would be surrendered to the landowner.

2.3.8 CAPITAL AND OPERATING COSTS

The total estimated cost of the Whistling Ridge Energy Project at the completion of construction would be over $150 million, which includes the wind turbines and associated equipment.

Whistling Ridge Energy LLC estimates that the annual operating and maintenance costs would be approximately $3.75 million, including the following:

- Wages and salaries of operation, maintenance, and administrative personnel
- Procurement of goods and services
- Insurance
- Sales and other state and local taxes
SECTION 2.4 ENERGY TRANSMISSION SYSTEMS
(WAC 463-60-155)

The project’s electrical system would consist of two key elements: (1) a collector system, which would collect energy generated at 575 volts from each wind turbine, transform the voltage to 34.5 kV using a pad-mounted transformer, and deliver the energy via underground cables to (2) the project substation, which would further transform the energy delivered by the underground collector system from 34.5 kV to 230 kV and deliver it, via new interconnection facilities to be built by BPA, to the adjacent existing BPA transmission line and into the regional transmission system. The BPA transmission lines are outside the scope of this application. Please see Section 2.3.3.4 for a more detailed description of the collector system.

No transmission facilities would be constructed by Whistling Ridge Energy LLC.
SECTION 2.5 WATER SUPPLY SYSTEM  
(WAC 463-60-165)

2.5.1 WATER INTAKE AND CONVEYANCE FACILITIES

Project operations would not require the use of any water for cooling or any other use aside from the limited needs of the Operations and Maintenance facilities. There would be no industrial wastewater stream from the project. Wastewater discharge would come from the Operations and Maintenance building discharging to an on-site septic system. The anticipated use is expected to be less than 5,000 gallons per day for kitchen and bathroom use. Potable water intake would be in the form of a well accommodating the Operations and Maintenance facilities’ needs. Whistling Ridge Energy LLC would seek and obtain approval for the new well from EFSEC, in consultation with Skamania County Environmental Health Department and the Washington State Department of Ecology (Ecology). No wastewater would be used, discharged or recycled for wind turbine operations.

2.5.2 WATER SUPPLY AND USAGE ALTERNATIVES

2.5.2.1 Water Supply Alternatives

Due to the low volume of water that would be required for operational use (approximately 5,000 gallons/day), Whistling Ridge Energy LLC did not consider alternatives to reclaim water or other water reuse projects.

2.5.2.2 Water Conservation Methods

The project would not generate process water or any point source discharge to surface waters or ground waters beyond the Operations and Maintenance facilities. The potable water well and septic system provide bathroom and shower facilities to the maintenance personnel. Additional water for daily operational use is minimal and would not result in a long-term increase on current demands. Where appropriate, water use for Operations and Maintenance, and daily operational needs would be minimized.

2.5.3 WATER RIGHTS AND AUTHORIZATIONS

Whistling Ridge Energy LLC is not requesting any new water rights or authorizations beyond the well for the Operations and Maintenance building described above. Operational daily water needs would be acquired from the well, and water needs related to construction would be purchased by the contractor from an off-site vendor with a valid water right and transported to the site in water-tanker trucks. This would be a short-term construction related impact on water use.

2.5.4 PROCESS WATER

No process water would be required for the project beyond daily water needs for the Operations and Maintenance building.
2.5.5 POTABLE WATER

Potable water would be supplied by the well that would be drilled for the Operations and Maintenance facilities.

2.5.6 MITIGATION MEASURES

Mitigation measures and best management practices (BMPs) have been incorporated in the project design features. These measures include avoidance of stream crossings to the maximum extent feasible; complying with federal, state, and local ordinances; and implementing a Stormwater Pollution Prevention Plan (SWPPP) and BMPs during and after construction.
SECTION 2.6 SYSTEM OF HEAT DISSIPATION  
(WAC 463-60-175)

Pursuant to WAC 463-60-115, Whistling Ridge Energy LLC requests a waiver of the information required by WAC 463-60-175, which calls for a description of the heat dissipation systems.

The heat dissipation from a wind turbine is minimal. Air cooling would be used to cool the operating machinery, such as the generator and gearbox inside the wind turbines, and no water resources would be used.
SECTION 2.7 CHARACTERISTICS OF AQUATIC DISCHARGE SYSTEMS (WAC 463-60-185)

Pursuant to WAC 463-60-115, Whistling Ridge Energy LLC requests a waiver of the information required by WAC 463-60-185, which calls for a description of the discharge to a watercourse. The project would use wind as its source of energy production only. There would be no discharge to a watercourse.

The water use of the proposed facility would be from a small well at the Operations and Maintenance building. This well would provide water for bathroom and kitchen use, as well as for some minor normal maintenance use, and would be expected to consume less than 5,000 gallons per day. Wastewater from the Operations and Maintenance facility would be discharged to a septic tank permitted and installed according to Skamania County Community Development Department standards.
SECTION 2.8 WASTEWATER TREATMENT  
(WAC 463-60-195)

Pursuant to WAC 463-60-115, Whistling Ridge Energy LLC requests a waiver of the information required by WAC 463-60-195, which calls for a description of wastewater treatment. The project would use wind as its source of energy production only and no water or wastewater would be used or discharged in that process. There would be no wastewater treatment or discharge to a watercourse.

The water use and disposal of the proposed facility would be from a small well at the Operations and Maintenance building. This well would provide water for bathroom and kitchen use, as well as for some minor normal maintenance use, and would be expected to consume less than 5,000 gallons per day. Wastewater from the Operations and Maintenance facility would be discharged to a septic tank permitted and installed according to Skamania County Community Development Department standards.
SECTION 2.9 SPILLAGE PREVENTION AND CONTROL
(WAC 463-60-205)

2.9.1 PURPOSE AND SCOPE

This section establishes requirements for a construction spill prevention, control, and countermeasure plan (SPCCP) for activities at the Whistling Ridge Energy Project, as required by the State of Washington Site Certification Agreement, and by state and federal requirements. A revised procedure would be issued as the project moves to operation, or if new requirements or organizational changes require revision. The procedure would be reviewed annually at a minimum, and updates made as needed.

2.9.2 SPILL PREVENTION PLAN

Responsibilities would be established for the construction period, in which the construction contractors would have primary responsibility for overseeing compliance with state and federal environmental regulations and compliance with environmental commitments made to EFSEC. Construction contractor personnel would oversee field activities; coordinate resolution of deviations from BMPs, commitments and regulations; and identify any process changes that could require revision to the environmental procedures.

Whistling Ridge Energy LLC shall have the overall responsibility to ensure compliance with state and federal environmental regulations and compliance with environmental commitments made to EFSEC.

2.9.2.1 Construction Spill Prevention

Fuel and lubricating oils from construction vehicles and equipment and the mineral oil used to fill the transformers are the only potential sources for a spill prevention control program during construction activities. The contractor would be responsible for training its personnel in spill prevention and control and, if an incident occurs, would be responsible for containment and cleanup.

During construction, the contractor would utilize fuel trucks for refueling of construction vehicles and equipment at existing licensed gas stations in nearby communities. There would be no fuel storage tanks used at the project site; instead, fuel trucks would refuel vehicles and equipment. The fuel trucks would be properly licensed.

The project would have up to 50 pad-mounted transformers (one at the base of each wind turbine) which arrive on site pre-filled with mineral oil. As part of the commissioning process of the main substation transformers, they would be filled and tested. The fuel and oil trucks would incorporate features in equipment and operation, such as automatic shut-off devices, to prevent accidental spills. Lubricating oils used during construction would mostly be contained in the vehicles and equipment for which they are used.

A Construction SPCCP would be submitted and approved by EFSEC prior to construction.
2.9.2.2 Operations Spill Prevention

Project operations would not require the use of a permanent fuel storage tank, as fuel use during operations is limited to maintenance vehicle fueling, which would be done at existing licensed gas stations in nearby communities (White Salmon and Hood River). The potential for accidental spills during operation is minimal, as the only materials used during project operations that present any potential for accidental spills are lubricating oils and hydraulic fluids used in the wind turbine generators and transformers.

Table 2.9-1 lists the fluids contained on site, including fluids for the turbines.

Table 2.9-1

It is anticipated that an Operation SPCCP would be submitted and approved by EFSEC prior to operation.

Wind Turbine Generator Fluids

Each turbine model has different specification for lubricating oil and hydraulic fluid quantities. There are three main types of fluid in a wind turbine generator: cooling fluid for the generator (a mix of glycol and water, similar to that used in automobile radiators), lubricating oil for the gearbox (typically a synthetic lubricating oil), and hydraulic oil for operating the blade pitch system, yaw mechanism, and brakes.

All of the wind turbine generators being considered for the project are equipped with sensors to automatically detect loss in fluid pressure and/or increases in temperature that enable them to be shut down in case of a fluid leak, as well as fluid catch basins and containment systems to prevent any accidental released from leaving the nacelle. Based on the limited quantities of fluids contained in the wind turbine generators and the leak detection and containment systems engineered into their design, the potential for an accidental spill from wind turbine generator malfunction is extremely limited. Furthermore, any accidental gear oil or other fluid leaks from the wind turbines would be contained inside the turbine towers, which are sealed around the base.

The fluids within the turbines are checked by staff periodically and must be replenished or replaced on an infrequent basis (generally less than once per year and sometimes only once every five years). When replacing these fluids, the typical current practice is for staff to climb up to the nacelle and remove the fluids in small (typically five-gallon) containers and lower them to the ground using a small maintenance crane built into the nacelle itself. The containers would then be transferred to a pickup truck for transport to the Operations and Maintenance facility for...
temporary storage (typically less than one month) before being picked up by a licensed transporter for recycling. Replacement fluids are added in the same method, only in reverse. Small quantities of replacement fluids, typically no more than a few 50-gallon drums, of lubricating oil and hydraulic oil may be stored at the Operations and Maintenance facility for replenishing and replacing spent fluids. These fluids would be stored in appropriate containers. All operations staff would be trained in appropriate handling and spill prevention techniques to avoid any accidental spills. Because only small quantities of fluids are transported, added, or removed at any one time and are stored for short periods of time, the potential for an accidental spill during routine maintenance is extremely limited.

Transformer Mineral Oil Coolant

Pad Mounted Transformers. As described in Section 2.3, Construction on Site, each wind turbine generator has a pad mounted transformer located at its base. These transformers contain mineral oil which acts as a coolant. Each pad mounted transformer contains up to 500 gallons of mineral oil. The transformer is designed to meet stringent electrical industry standards, including containment tank weldment and corrosion protection specifications.

Substation Transformer(s). As described in Section 2.4, Energy Transmission Systems, the entire project would be electrically connected to the grid at the BPA substation, which would be equipped with either one or two transformers. Each substation transformer contains up to 12,000 gallons of mineral oil for cooling. The transformer is designed to meet stringent electrical industry standards, including containment tank weldment and corrosion protection specifications. The substation transformers are equipped with an oil level sensor that detects any sudden drop in the oil levels, and sends an alarm message to the central supervisory control and data acquisition (SCADA) system. Finally, the substation transformers are supported by a concrete vault to ensure that any accidental fluid leak does not result in any discharge to the environment.

2.9.2.3 Spill Procedures

Procedures for what to do in the event of a spill shall be developed. These would include actions needed to contain the material in accordance with training received:

- Absorbent booms would be placed around the area of a spill if it is believed that the spill could travel outside immediate area. For spills to the ground, if appropriate for the material spilled, turn soil and use absorbent materials to collect additional spilled material. Contaminated absorbent materials shall be collected and disposed of in accordance with the SPCCP.

- If the spill is large enough to require a cleanup company’s assistance, or cleanup requires training beyond level provided to site personnel, a contractor for cleanup services would be hired to perform the work at the responsible party’s expense.

- Spills would be reported as required by the SPCCP
• All spills would be reported to EFSEC and Ecology using the guidance provided in the SPCCP.

2.9.2.4 Record Retention

All records pertaining to SPCCP shall be retained on site for a minimum of five years.
SECTION 2.10 SURFACE WATER RUNOFF
(WAC 463-60-215)

Surface water runoff without regulated controls can cause the erosion of topsoil, increase sediment load of surface water bodies, and increase the temperature and deteriorate the water quality of receiving creeks. These impacts are mitigated by the requirements of stormwater control programs.

The discharge of stormwater runoff from the Whistling Ridge Energy Project would be regulated by EFSEC based on Ecology’s stormwater pollution control program. This program is based on federal regulations adopted to implement Section 402(p) of the Federal Clean Water Act and Chapter 90.48 RCW, the state of Washington's Water Pollution Control Act. The goal of the stormwater program is to reduce or eliminate stormwater pollution from municipal and industrial point sources, by requiring the implementation of a technology-based SWPPP and to eliminate violations of surface water quality standards caused by stormwater.

Whistling Ridge Energy LLC may be required by EFSEC to obtain coverage under the Construction Stormwater General Permit because it would disturb more than one acre of land. Unless if is instructed by EFSEC that it is not necessary to do so, Whistling Ridge Energy LLC would file a notice of intent (NOI) to obtain coverage under the Construction Stormwater General Permit and the Industrial Stormwater General Permit. Even if coverage under this general permit is not required, the Applicant proposes to design and implement the same BMPs to prevent and minimize the discharge of pollutants in its stormwater runoff, and to prepare SWPPPs for the construction and operation of the Whistling Ridge Energy Project in substantially the same form and content.

The final design would conform to the applicable Ecology Stormwater Management Manual in effect at the time or as instructed by EFSEC.

The NOI for construction activities would be filed with EFSEC prior to the start of construction. A SWPPP meeting the conditions of the Stormwater General Permit for Construction Activities also must be prepared and implemented prior to the start of construction activities. The content of the SWPPP for construction activities is addressed in Section 2.10.1.

The NOI for Industrial Activities would be filed with EFSEC if required.

2.10.1 STORMWATER EROSION CONTROL DURING CONSTRUCTION

This section cites specific procedures and requirements that would be implemented at the construction site to reduce the discharge of contaminated stormwater runoff. It includes information on the erosion control practices to be followed during construction at the site (Section 2.10.1.1). Site-specific erosion control plans would be submitted to EFSEC prior to construction.

The main categories of information to be included in the SWPPP are construction BMPs, operating BMPs, construction phase enforcement, and establishment of the Whistling Ridge Energy Project stormwater pollution prevention team.
The SWPPP is most appropriately prepared when design-level topographic surveying and mapping is available, and the final configuration of proposed improvements is overlain on the existing topographic map. The civil site design engineer would establish the locations and types of construction BMPs to be required of the construction contractor, and would include these on an overall map of the site. A narrative section of the SWPPP would describe the intended installation sequence and function of the selected BMPs, and present the sizing calculations. The report also would identify the selected minimum standard to which each of the BMPs are to be constructed or installed. When prepared at this level of detail, the document would meet the requirements of the Stormwater Construction Activity NPDES permit system, and also accurately describe, to the construction contractor, the improvements and actions to be required during construction. The document would be submitted to EFSEC for approval prior to construction. Implementation of the construction BMPs is carried out by the site work contractor, with oversight by environmental monitors.

2.10.1.1 Site Construction

During construction, all new and improved roads would have a 20-foot-wide buffer on one side of the roadway, the maintenance yard and substation plot would have a 50-foot perimeter buffer, turbines would have 300-foot circular buffers, overhead transmission lines would have 50-foot-wide buffers, and underground transmission lines would have 15-foot-wide buffers. Trenches up to 3 feet wide and 3 to 4 feet deep would be dug along access roads for the underground electric cables, with an anticipated 30-foot-wide disturbance area during construction. Trenching would occur simultaneously with roadway construction and improvements to minimize impacts.

Site-specific BMPs for temporary erosion and sedimentation control during construction would be identified on the construction plans submitted to EFSEC, to mitigate impacts associated with construction activities. BMPs would be selected from the applicable Stormwater Management Manual as appropriate for the site slopes, the construction activities, and weather conditions.

The sequence and methods of construction activities would be controlled to limit erosion. Clearing, excavation, and grading would be limited to the minimum areas necessary for construction of the project, and would not be performed far in advance of facility construction. Slopes would be graded to no steeper than 3 feet horizontal (H) to 1 foot vertical (V). Ground surface restoration shall be completed within fourteen days of the area’s final disturbance. Interim surface protection measures, such as erosion control blankets or straw matting, also may be required prior to final disturbance and restoration if warranted by the potential for erosion.

Sediment control measures used during construction would be based on a 10-year design storm. Water quality measures (other than sediment removal) would be based on the 6-month, 24-hour design storm.

All construction practices would emphasize erosion control over sediment control through non-quantitative activities such as:

- Straw mulching and vegetating disturbed surfaces
- Retaining original vegetation wherever possible
• Timing grading operations to dry seasons
• Directing surface runoff away from denuded areas
• Keeping runoff velocities low through minimization of slope steepness and length
• Providing and maintaining stabilized construction entrances

In order to prevent erosion and control sediment migration, the following BMPs could be used.

**Sediment Traps**

Sediment traps are temporary or permanent basins used to intercept stormwater runoff and allow sediment to settle, thereby minimizing the amount of sediment flowing off site. Sizing criteria for the traps include inflow and sediment load. Sediment traps would be sized for the specific disturbed area, for bare soil conditions, and typically for 75 percent sediment removal efficiency.

**Silt Fences**

Slopes less than 3H:1V would be protected with silt fencing as appropriate. Silt fences would be installed in locations where they would trap silt eroded from slopes during construction and prior to reestablishing vegetation. The maximum flow path to each silt fence would be approximately 100 feet. No concentrated flows greater than 1 cubic foot per second would be directed toward any fence for the 25-year storm. Silt fences would be maintained throughout the construction period, and beyond until disturbed surfaces have been stabilized with vegetation. Silt fence construction specifications including fabric equivalent open size, support spacing, and total length would be determined by local construction conditions during final design of the facilities.

**Grade Control Structures and Slope Ditches**

Grade control structures such as rock check dams, hay bale check dams, dikes, and swales would be used where appropriate to reduce runoff velocity, as well as to direct surface runoff around and away from cut-and-fill slopes. Swales and dikes also would be used to direct surface water on top of the filled pad toward sediment traps and away from flowing over the bank, which may contribute to sheet and rill erosion.
Matting and Erosion Control Blankets

Depending on weather conditions during the construction period, straw or jute matting or other suitable erosion control blankets would be used on any disturbed slopes to prevent erosion and control sediment migration.

Quarry Spall Construction Entrances

Quarry spall construction entrances would be used to reduce migration of construction dirt to public roads. Placing the construction entrances is one of the first activities required at the site, but the rock bed also must be periodically replenished as it becomes dirty or migrates into the subgrade. All construction traffic would be directed to use the construction entrances.

Chemical Source Control

In addition to erosion and sedimentation control on the site, it is also important to reduce potential for chemical pollution of surface waters during construction. Since source control is the most effective method of preventing chemical water pollution, careful control must be exercised over potentially polluting chemicals used on site during construction. The EPC Contractor with oversight from Whistling Ridge Energy LLC would be responsible for planning, implementing, and maintaining BMPs for:

- Neat and orderly storage of construction chemicals and spent containers in lined, bermed areas
- Prompt cleanup of construction phase spills
- Regular disposal of construction garbage and debris

The SWPPP would identify all areas of potential chemical storage during construction, and provide appropriate control measures.

2.10.2 PERMANENT STORMWATER MANAGEMENT

Vegetation in the project area consists of Grass-forb Stand, Brushfield/Shrub Stand, Conifer-Hardwood Forest, Conifer Forest, and Riparian – Deciduous. The current vegetation conditions are heavily influenced by the commercial forest production activities that occur in the area. The total site area is approximately 1,152 acres; however, stormwater impacts from disturbed areas would be generated from less than 110 acres. Approximately 7.2 miles of gravel roads would be improved, and approximately 2.4 miles of gravel roads would be constructed. During operation, all roads would be maintained to a width of approximately 25 feet, with a 5-foot shoulder on each side, with the exception of roadways adjacent to turbine strings, which would be 40 feet wide with a 25-foot graveled corridor and 5-foot shoulder on each side. The maintenance yard would cover approximately 2 acres, which would include an approximately 3,000-square-foot Operations and Maintenance building and an adjacent gravel parking area for employees, visitors, and equipment. Other additions to the site include a 5-acre gravel substation site, a collector system transformer on a
9’x9’ concrete pad, and concrete pads for the approximately 50 wind turbines. These permanently improved areas would cover approximately 55 acres (less than 5% of the total project area).

Permanent stormwater management requires construction of appropriate stormwater hydraulic and treatment facilities, routine maintenance thereof, and prevention of chemical pollution through source control. Whistling Ridge Energy LLC would be responsible for developing, implementing, maintaining, and modifying the SWPPP.

As described above, improvements to the site would cover only a small portion of the project area (less than 5%), most of which would be graveled surfaces. Completely impervious surfaces would be limited to the concrete pads for the turbines and the Operations and Maintenance building, totaling less than one acre. The majority of the improved area is composed of roads or parking surface, which are likely to be compacted over time due to vehicular traffic, causing a decrease in the infiltration capability of those areas. However, some infiltration in those areas is still expected, and they are not classified as impervious. Due to the relatively small areas of impact, site surface water runoff is expected to increase only slightly due to these activities, and considered to be negligible. Vegetated ditches would be installed along roads to provide for hydraulic and treatment facilities. Stormwater would be conveyed via these vegetated roadside ditches and pass through culverts prior to discharging to the natural drainage ways on site. Inlets and outlets of culverts would be stabilized to prevent scour.

Due to the steep nature of the site, some of the improved and constructed roadways would be relatively steep. After construction, until the site has been stabilized, these areas would be most susceptible to erosion and sediment migration. Steep slopes with exposed soil would be seeded with a native mix and protected with mulch or something equivalent until the vegetation is established. Vegetation of disturbed areas and roadside ditches, as well as stabilization of inlets and outlets to culverts, would be the primary permanent stormwater management control measures.

The SWPPP would contain pre-design level of detail for these permanent stormwater BMPs, and would establish the permanent operations stormwater pollution prevention team from appropriate employee categories. Final designs for the permanent BMPs would be incorporated into the final construction plans and specifications prepared by the civil site design engineer. An operations manual for the permanent BMPs would be prepared by the civil site design engineer, if necessary, and the stormwater pollution prevention team members.

The constructed permanent stormwater BMPs would include:

- Vegetated drainage ditches
- Culverts with stabilized inlets and outlets
- Permanent erosion and sedimentation control through site landscaping, grass, and other vegetative cover

Due to the small area of impervious surface in the project area, no detention storage is required.
Runoff treatment BMPs facilities would be designed to conform to the applicable Stormwater Management Manual.

Operational BMPs would be adopted as part of the SWPPP to implement good housekeeping, preventive and corrective maintenance procedures, steps for spill prevention and emergency cleanup, employee training programs, and inspection and record keeping practices as necessary to prevent stormwater pollution.

Examples of good operational housekeeping practices that would be employed at the Whistling Ridge Energy Project site include:

- Neat and orderly storage of chemicals under cover in the Operations and Maintenance facilities
- Prompt cleanup and removal of spillage
- Regular pickup and disposal of garbage and rubbish
- Prevention of accumulations of liquid or solid chemicals on the ground or the floor

At least annually, facility operators would receive spill response training and training in the applicable pollution control laws and regulations. Additional support staff would be trained in the following spill response procedures:

- Recognizing areas that may be affected by a spill and potential drainage routes
- Reporting spills to appropriate individuals
- Employing appropriate material handling and storage procedures
- Implementing spill response procedures

Whistling Ridge Energy Project site operators must periodically review the SWPPP against actual practice. They must confirm that the controls identified in the plan are adequate, and that employees are following them. They must further test and confirm that non-permitted discharges to the stormwater system are not occurring. A summary of these in-house compliance inspections shall be kept with the SWPPP, along with any notifications of non-compliance and reports on incidents such as spills. If the SWPPP has been followed but still proves inadequate to prevent stormwater pollution, Whistling Ridge Energy LLC would amend the SWPPP and seek EFSEC concurrence with the improvements.
2.10.3 PERMANENT WATERWAYS

No perennial streams are located in or adjacent to the Whistling Ridge Energy Project. Five intermittent drainage ways have been identified on site, ultimately draining to the east of the project site. Runoff is conveyed via these drainage ways, and additional ditches in the southwest portion of the site downslope to perennial streams outside the project site that eventually drain to the Columbia River. Additional details regarding water sources and pathways are identified in Sections 3.3, Water and Section 3.5, Wetlands.
SECTION 2.11 EMISSION CONTROL  
(WAC 463-60-225)

2.11.1 INTRODUCTION

Pursuant to WAC 463-60-115, Whistling Ridge Energy LLC requests a waiver of the information required by WAC 463-60-225 for operation, which calls for a demonstration that the highest and best practicable treatment for control of emissions would be utilized. The air quality impacts from construction of the project would be temporary and minor, and would be limited to vehicle emissions and fugitive dust emissions. No air emissions would be generated from operation of the Whistling Ridge Energy Project, as the operation of wind turbine generators does not involve the combustion of any fuels. The project site is located outside of any air quality non-attainment areas, according to Ecology.

2.11.2 CONSTRUCTION

During construction of the project, the use and operation of construction equipment and vehicles would result in minor air emissions. The main sources of these emissions are expected to be:

- Earth-moving equipment for road construction and site preparation
- Excavating equipment for turbine foundation excavation
- Transport vehicles for delivery of construction materials and equipment
- Worker vehicles
- Small electric generators for on-site power during construction

Fugitive dust emissions would be caused by disturbing the land for construction of project facilities and construction traffic.

The primary types of air emissions are expected to be those typically associated with internal combustion engines, e.g., carbon dioxide, nitrogen oxides, sulfur oxides, carbon monoxide and particulate matter.

2.11.3 OPERATION

The generation of electricity using wind turbines does not produce air emissions. During project operation, small amounts of fugitive dust emissions would be caused by occasional maintenance vehicles traveling on the gravel access roads. However, the number of vehicle trips associated with ongoing Operations and Maintenance would be minor and it is unlikely that the resulting dust would reach nuisance levels or would be substantially different in quantity or type from dust caused by existing logging operations and related traffic.
Operation of the proposed project would not result in emissions that exceed that significant emission rates and would not contribute to violations of the National Ambient Air Quality Standards (NAAQS). Impacts to air quality from project operation would be insignificant.

2.11.4 MITIGATION

All construction and operations vehicles and equipment would comply with all applicable state and federal emissions standards. Measures to control dust during construction would include the use of a dust control agent such as magnesium chloride, or possibly wetting down roadbeds and controlling construction vehicle speeds. Use of a dust control agent would be the preferred method over the use of water as it would also minimize water truck traffic.

The certificate holder would instruct the contractors to minimize the idling of engines when not in active use to minimize emissions.
Whistling Ridge Energy LLC would be responsible for the construction of the Whistling Ridge Energy Project.

2.12.1 INTRODUCTION

The construction of the Whistling Ridge Energy Project would be performed in several stages and would include the following main elements and activities:

- Grading the field construction office area (also used for Operations and Maintenance facilities)
- Constructing site roads, turn-around areas, and crane pads at each wind turbine location
- Constructing the turbine tower foundations and transformer pads
- Installing the electrical collection system – underground and some overhead lines
- Assembling and erecting the wind turbines
- Constructing and installing the substation
- Plant commissioning and energization

The Applicant intends to enter into two primary agreements for the construction of the project: (1) an agreement for the supply, erection and commissioning of the wind turbines, and (2) an Engineering, Procurement, and Construction (EPC) contract for the construction of the balance of the project, which includes all other project facilities and infrastructure such as the roads, electrical collection system, substation, Operations and Maintenance facility, etc. The turbine supplier and the EPC Contractor would be selected during the EFSEC Application review process.

The construction schedules discussed below are based on obtaining a site certificate from Washington EFSEC by April October 2010.

The construction schedule would closely follow the construction methodologies discussed in Section 2.14, Construction Methodology.

2.12.2 CONSTRUCTION SCHEDULE AND MILESTONES

Table 2.12-1 identifies the major schedule milestones, engineering and procurement, construction and start-up. Assuming the Governor’s approval of the Site Certification agreement in April October 2010, Whistling Ridge Energy LLC anticipates beginning design and construction in 2010-2011 and operation by 2014-2012. The construction schedule would be
revised according to the actual approval of the Site Certification Agreement, and a copy provided to EFSEC at least sixty (60) days prior to the start of construction.

SECTION 2.13 CONSTRUCTION MANAGEMENT  
(WAC 463-60-245)

2.13.1 CONSTRUCTION MANAGEMENT ORGANIZATION

Whistling Ridge Energy LLC would enter into two primary agreements for the construction of the project: (1) agreement for the supply, erection and commissioning of the wind turbines, and (2) an EPC contract for the construction of the balance of the project, which includes all other Project facilities and infrastructure such as the roads, electrical collection system, substation, Operations and Maintenance facility, etc.

2.13.1.1 Project Construction Management

The project management organizational structure would include two support groups: an engineering and design specifications team and the field site management team. Figure 2.13-1 illustrates the construction management organizational structure for the project. The Project Manager would handle contractual aspects of the agreements with the project managers of the wind turbine vendor and the EPC contractor. This organization chart represents a typical structure for wind power projects. The exact organization may change after award of the turbine supply contract, EPC contract, or other subcontracts.

2.13.1.2 Engineering and Design Specifications Team

The engineering and design specifications team would be responsible for establishing the design and construction specifications for the various portions of the project. The engineering team acts as a third party verification group in conjunction with the project’s field quality assurance/quality control (QA/QC) team. The engineering team would review proposals from the various turbine suppliers and EPC contractors for equipment supply and construction work. The turbine supplier and EPC contractor would be responsible for the detailed design work for the project and for submitting these designs and equipment specifications to the project engineering team for review. Review by the project engineering team would ensure that the detailed construction plans would meet the required design specifications, codes, and standards for the project.

2.13.1.3 Field Site Management Team

The field site management team would oversee construction on site and ensure that construction on site is performed in accordance with the engineering plans and specifications, environmental requirements and good industry practice. The field site team would generally be involved in day-to-day issues that arise throughout the construction phase. The Project Site Manager would have a support team consisting of QA/QC specialists, environmental inspectors, and site safety officers. The site team also would rely on the engineering team for support in the field during critical operations such as energizing of the substation and any technical issues that arise during project construction.
Project Construction Management Organizational Structure

Whistling Ridge Energy Project
Skamania County, Washington

Figure 2.13-1
2.13.1.4 EPC Contractor’s Construction Management Team

The EPC Contractor would be responsible for managing several construction subcontractors including those for the balance of plant items, such as the roads, electrical and communications system infrastructure, substation and Operations and Maintenance facility. The EPC Contractor would have a lead Project Manager, a Project Engineer, and a Site Manager supported by their field engineering team, QA/QC specialists, environmental monitors, and site safety officers. The EPC Contractor would be required to implement and perform a safety plan, a QA/QC plan and an environmental protection plan, including the SWPPP.

2.13.1.5 Wind Turbine Vendor’s Construction Management Team

The wind turbine supplier would be responsible for the supply, delivery, erection and commissioning of the wind turbines. The turbine supplier’s construction team would include a lead Project Manager, a Site Manager, transportation specialists, and several lead technicians. The turbine vendor’s site team would be supported by their own QA/QC specialists and site safety officers. The EPC Contractor would be required to implement and perform a safety plan, a rigorous QA/QC plan, and a detailed commissioning plan.

2.13.1.6 Project Operations and Maintenance Team

The project Operations and Maintenance group would be on site during the commissioning and start-up phase of construction. Once a turbine is commissioned, it is turned over to the Operations and Maintenance group control. The Operations and Maintenance team generally consists of a Project Site Manager, a team of wind turbine field technician specialists, and an administrative support staff.

2.13.2 SAFETY PROGRAM

Prior to the commencement of any construction work, the EPC Contractor would be required to prepare a safety plan that would apply to EPC Contractor personnel and all subcontractor personnel working at the site. The plan would be designed to ensure compliance with all laws, ordinances, regulations, and standards concerning health and safety. The EPC Contractor would have a safety manager with the authority to issue a “stop work” notice when health and safety issues are violated, including any subcontractor safety issues, and the health and safety of construction personnel are in danger. Upon identification of a health and safety issue, the safety manager would work with the responsible department or subcontractor to correct the issue.

2.13.3 ENVIRONMENTAL PROTECTION PROGRAM

The environmental compliance program would ensure that construction activities meet the conditions, limits, and specifications set in environmental standards established in the Site Certification Agreement and all other environmental regulations.

Copies of all applicable construction permits would be kept on site. The lead project construction personnel and construction Project Managers would be required to read, follow, and
be responsible for all required compliance activities. A project Environmental Monitor would be responsible for ensuring that all construction permit requirements are adhered to, and that any deficiencies are promptly corrected. The Environmental Monitor also would have the authority to stop work. The environmental compliance program would cover avoidance of sensitive areas during construction, waste handling and storage, stormwater management, spill prevention and control, and other components required by State and County regulations.

2.13.4 TRAINING PROGRAMS

Each EPC Contractor would be required to have a training program to ensure that safety and environmental regulations and permits are followed. The program would include training on:

- Drug and alcohol free workplace policy
- Personal health and safety
- Fall safety
- Confined space
- Excavation
- Crane and rigging
- Equipment and operations safety
- Fire prevention
- Electrical safety
- Emergency response
- Hazards communication
- Stormwater pollution prevention
- SPCCP
- Uptower rescue plan

During operations, personnel would receive initial and annual training. In addition to training to support proficiency on the Operations and Maintenance required for the facility, personnel would receive training related to health and safety, hazards communication, stormwater pollution prevention, and SPCCP.
2.13.5 QUALITY CONTROL SYSTEMS AND RECORD KEEPING

A QA/QC program would be implemented during all phases of the project to ensure that the engineering, procurement, construction, and startup of the facility are completed as specified. The elements of the QA/QC program would include:

- A formal QA/QC program would be in place to ensure that the equipment suppliers deliver their components as designed and specified and that the installation of equipment is completed as specified.

- A procedures manual would be developed that describes Whistling Ridge Energy Project activities from the initiation of final design activities through startup of the plant.

- The EPC Contractors would describe the activities and responsibilities within their organizations, and measures taken to assure quality work. Some of the topics would include design control, configuration management, and drawing control.

- Independent QA/QC personnel would review all documentation and witness field activities as a parallel organization to that of the construction organization to assure compliance with the specifications.

- Field inspectors’ acceptance would be required for the installation, alignment, and commissioning of all major equipment.

Typical QA/QC checks include:

- Factory QA/QC
  - Inspection of major equipment at manufacturer’s facilities
  - Review and inspection of third party test verification reports
  - Review and inspection of manufacturer’s QA/QC procedures
  - Manufacturing drawing review and verification
  - Visual inspection
  - Witness and/or review of testing
  - Verification of welding procedure specifications compliance
  - Inspection of flange interface flatness measurements, finishing, and protection
  - Witness or review of turbine run-in load testing
  - Inspection of paint finishing and protection
  - Shipment packaging and handling, tracking, and identification
  - Pre-commissioning field testing and verification

- Field Inspection QA/QC
  - Reviewing equipment and material delivery acceptance inspection procedures
  - Inspection of all critical interfaces
  - Verification of all mechanical assembly work including erection of major components
- Verification of field wiring and tagging
- Pre-commissioning field testing and verification

- Concrete/Structural
  - Inspection of forms, structural steel, and rebar prior to backfilling and prior to casting
  - Field engineer’s witness of concrete pouring
  - Inspection of concrete testing during pour (slump) and verification of break test results

- Roads
  - Field verification of road locations to site plan and survey markings
  - Review of clearing process (if necessary)
  - Verification of adequate road materials and compaction to engineer’s specifications
  - Verification of road grade to plans

- Electrical Collection System
  - Inspection of cables and trenches prior to burial and backfilling
  - Witness of proper backfilling procedures
  - Inspection of terminations and termination hardware
  - Witness and/or review of polarity, cable marking, and phase rotation tests
  - Witness and/or review of grounding system resistance measurements
  - Inspection of all lock-out/tag-out locations and energizing sequences and plan

- Transformers
  - Inspection of transformers at manufacturer’s facilities
  - Witness and/or review of winding resistance, polarity and phase displacement tests
  - Witness and/or review of no load losses and excitation current at rated voltage and frequency
  - Witness and/or review of impedance voltage and load losses at rated current and rated frequency
  - Witness and/or review of high potential and induced potential tests
  - Witness and/or review of impulse tests, reduced full wave, chopped wave and full wave tests
  - Witness and/or review of regulation and efficiency calculations
  - Verification of compliance to engineering specifications
  - Inspection of painting/tagging/preparation for shipment
  - Verification of field wiring and tagging

- Breakers
  - Witness and/or review of rated continuous current and short circuit tests
  - Witness and/or review of dielectric withstand tests
− Witness and/or review of switching tests
− Witness and/or review of insulator tests
− Witness and/or review of mechanical life tests
− Witness and/or review of terminal loading tests
− Witness and/or review of partial discharge tests
− Verification of compliance to engineering specifications
− Inspection of painting/tagging/wiring/preparation for shipment
− Verification of field wiring and tagging

Whistling Ridge Energy LLC would periodically audit the EPC Contractor, including reviews of documentation and surveillances of field activities, to ensure compliance with the specifications and with the requirements of the QA/QC plan. Checks may include:

• Verification of drawings
• Verification of materials
• Verify compliance to engineering specifications
• Verify compliance with environmental permits and regulations
• Verify compliance with health and safety program

Records would be maintained at the on-site Operations and Maintenance building in accordance with Whistling Ridge Energy LLC’s records management program and state archivist requirements.
SECTION 2.14 CONSTRUCTION METHODOLOGY  
(WAC 463-60-255)

2.14.1 CONSTRUCTION SUMMARY

The proposed Whistling Ridge Energy Project would be located on private commercial forestland owned by S.D.S Co., LLC and Broughton Lumber Company in an unincorporated area of Skamania County, approximately 7 miles northwest of the City of White Salmon. Several private logging roads exist around the site. The project site is composed of complexes of very deep soils that formed in alluvium, colluvium, and residuum weathered primarily from basalt and mixed with volcanic ash (USDA NRCS 2003). The land is in commercial forest production and has been harvested.

Stormwater pollution prevention activities would occur prior to any clearing and site preparation. Measures would include installation of a stabilized construction entrance, wheel wash, silt fences, hay bales, temporary and/or permanent water conveyance systems, and installation of temporary and/or permanent retention ponds.

Before construction can commence, a site survey would be performed during the micrositing process to stake out the exact location of the wind turbines, the site roads, electrical cables, access entryways from public roads, substation areas, etc.

Once the surveys are complete, a detailed geotechnical investigation would be performed to identify subsurface conditions which would dictate much of the design work of the roads, foundations, underground trenching and electrical grounding systems. Typically, the geotechnical investigation involves a drill rig which bores to the engineer’s required depths (typically 8 inch diameter drill to 30-40 feet deep) and a backhoe to identify the subsurface soil and rock types and strength properties by sampling and lab testing. Testing is also done to measure the soil’s electrical properties to ensure proper grounding system design. A geotechnical investigation is generally performed at each turbine location, the substation location and at the Operation and Maintenance building location.

During construction, foundations would be installed, followed by installation of the equipment and construction of the Operations and Maintenance building. Approximately 5,000 amperes of 480-volt, three-phase temporary power would be installed within the site boundary to supply construction power. Startup power would be obtained by a step down transformer located adjacent to the high voltage switching station.

Field toilets and temporary holding tanks would be placed on site for use by construction personnel. During construction, potable water would be provided in containers until the potable water supply system is installed.

Construction worker parking would be provided primarily at the Operations and Maintenance/construction office area and throughout the project area where major activities are occurring. Materials to be used during construction are expected to be staged primarily at the
Operations and Maintenance building complex within a fenced storage yard and in two to three other areas to be determined after site surveys are completed.

### 2.14.2 SITE PREPARATION AND ROAD CONSTRUCTION

Preliminary analysis by URS Corporation indicates that the potential for liquefaction is very low at this site. Based on test pits and field observations, unconsolidated soils extend up to 3 feet below ground surface. The surficial soils are primarily characterized as soft, moist sandy silt, clay and sand. Immediately beneath the unconsolidated soils, rock with variable strength and weathering properties is present. It is anticipated that rock quality of the basalts would improve with depth but that weaker interflow zones consisting of volcanioclastic material and paleosols are possible at any depth. Prior to final design and location of the tower foundations, additional subsurface investigations (boreholes) would be required to provide geotechnical data at foundation and anchor depths. The final determination of foundation type would be determined by the EPC contractor’s geotechnical engineer in consultation with the turbine manufacturer.

During site preparation, the contractor would install storm water pollution prevention measures. Dust would be controlled as needed by spraying water on dry, exposed soil. A Certified Erosion and Sediment Control Lead would be responsible for ensuring that storm water pollution prevention measures meet BMPs in accordance with the most recent version of Ecology’s applicable Stormwater Management Manual.

Roadway access would be provided using Cook-Underwood Road to Willard Road. A new connection would be made directly from Willard Road to West Pit Road and West Pit Road would be improved. West Pit Road is an existing private logging road of approximately 2.5 miles in length. West Pit Road was originally built to enable large trucks and logging equipment to access the project site for ongoing commercial logging purposes. This road was generally 8 to 12 feet wide, however improvements were made during summer 2009 for logging purposes to widths between 20 and 26 feet. Improvements to allow use by construction vehicles generally would involve additional widening to the roadway and the existing culvert, widening of some corners, and providing a gravel all-weather surface. West Pit Road would be widened to approximately 25 feet (width of finished road), with an additional 5 feet of shoulder on either side to provide access to the site by construction vehicles, and to continue to provide access for logging activities.

The project roads would be gravel surfaced and generally designed with a low profile. Road construction would be performed in multiple passes starting with the rough grading and leveling of the roadway areas, if necessary. Once rough grade is achieved, a fabric layer would be installed, base rock would be trucked in, spread and compacted to create a road base. A capping rock would then be spread over the road base and roll-compact to finished grade.

There are two existing quarry pits, one located on site and one on the project boundary along West Pit Road (see Figure 2.3-1). Both are under 3 acres in size and were established to support the commercial forestry use. There is a potential that some rock used for roadway surfacing of West Pit Road may come from one or both of these quarry pits. The quarries will remain at or below 3 acres in size, and West Pit Road will continue to be used for forest access. Alternatively, rock would be hauled in from off-site commercial quarries.
Excavated soil and rock that arises through grading would be spread across the site to the natural grade and would be reseeded with native grasses to control erosion by water and wind. Approximately 50 percent of excavated soils are anticipated to be too large for re-use as backfill at foundations. These larger cobbles would be crushed into smaller rock for use as backfill or road material or disposed of off-site. Those materials that cannot be reused on site would be disposed of in accordance with Skamania County and Ecology regulations for clean fill materials.

2.14.3 FOUNDATION CONSTRUCTION

The Project would require several foundations including bases for each turbine and pad transformer, and the Operations and Maintenance facility. Often, separate subcontractors are mobilized for each type of foundation they specialize in constructing.

Foundations and buildings would be designed for Seismic Zone 2. The initial phase of foundation construction would include foundations for all heavy equipment except for transformers and other electrical switchyard foundations, which would be constructed at a later time.

The presence of relatively shallow rock indicates that the proposed structures would be supported on rock anchored mat-slab foundations. Foundation construction would occur in several stages including drilling, blasting and hole excavation, outer form setting, rebar and bolt cage assembly, casting and finishing of the concrete, removal of the forms, backfilling and compacting, construction of the pad transformer foundation, and foundation site area restoration.

Excavation and foundation construction would be conducted in a manner that would minimize the size and duration of excavated areas required to install foundations. Portions of the work may require over excavation and/or shoring. Foundation work for a given excavation would commence after excavation of the area is complete. Backfill for the foundations would be installed immediately after approval by the engineer’s field inspectors. The Applicant plans on using on-site excavated materials for backfill to the extent possible.

Based on preliminary calculations and depending on the type of foundation design used, approximately 20 cubic yards of excavated soil would remain from each turbine foundation excavation. The excess soils not used as backfill for the foundations would be used to level out low spots on the crane pads and roads consistent with the surrounding grade and reseeded with a designated mix of grasses and/or seeds around the edges of the disturbed areas. Larger cobbles would be disposed of off-site, or crushed into smaller rock for use as backfill or road material. All excavation and foundation construction work would be done in accordance to a formal SWPPP for the project as outlined in Section 2.10, Surface Water Runoff.

Construction of foundations would require the use of a number of types of heavy equipment, including excavation equipment, concrete-pumping equipment, and concrete finishing equipment. In addition, light and medium duty trucks, air compressors, generators, and other internal combustion engine driven equipment are anticipated.
The EPC contractor, in consultation with the Applicant, would determine the need for an on-site concrete batch plant, rock quarries, and rock crushers.

### 2.14.4 ELECTRICAL COLLECTION SYSTEM CONSTRUCTION

Once the roads and turbine foundations and transformer pads are complete for a particular row of turbines, underground cables would be installed on the completed road section. If any unanticipated environmental, geological, or historic constraints are discovered, limited portions of above-ground electrical collection lines may be proposed. A trench is cut to the required depth with a rock trencher. Clean fill would be placed above and below the cables for the first several inches of fill to prevent cable pinching. All cables and trenches would be inspected before backfilling. Once the clean fill is covering the cables, the excavated material would then be used to complete the backfilling. Blasting would be used in areas where solid rock is encountered close to the surface, or a shallower trench would be cut using rock cutting equipment and the cables may be covered with a concrete slurry mix to protect the cables and comply with code and engineering specifications if site conditions warrant such coverage.

The high voltage underground cables are fed through the trenches and into conduits at the pad transformers at each turbine. The cables run to the pad transformers’ high voltage (34.5 kV) compartment and are connected to the terminals. Low voltage cables are fed through another set of underground conduits from the pad transformer to the bus cabinet inside the base of the wind turbine tower. The low voltage cable would be terminated at each end and the whole system would be inspected and tested prior to energization.

For overhead transmission, once the survey and design work are done, the installation of poles and cross-arms to support the conductors can commence. The poles are first assembled and fitted with all of their cross-arms, cable supports and insulator hardware on the ground at each pole location. Holes for each pole would then be excavated or drilled and the poles would be erected and set in place using a small crane or boom truck. Once it is set in place, concrete would be poured in place around the base of the pole, or clean fill would be compacted around the tower base according to the engineer’s specifications. The overhead lines would connect to underground cables at each end through a switchable, visible, lockable riser disconnect with fuses.

Excavated soil and rock that arises through grading would be spread across the site to the natural grade and would be reseeded with native grasses to control erosion by water and wind. Approximately 50 percent of excavated soils are anticipated to be too large for re-use as backfill at foundations. These larger cobbles may be crushed into smaller rock for use as backfill or road material or disposed of off-site. Those materials that cannot be reused on site would be disposed of in accordance with Skamania County and Department of Ecology regulations for clean fill materials. All excavation, trenching and electrical system construction work would be done in accordance to a SWPPP for the project as outlined in Section 2.10, Surface Water Runoff.

The electrical construction work would require the use of several pieces of heavy machinery including a track-hoe, a rock trencher, rock cutting equipment, front-end loaders, drill rigs for the pole-line, dump trucks for import of clean back fill, transportation trucks for the materials, small cranes and boom trucks for off-loading and setting of the poles and pad transformers, concrete
trucks, cable spool trucks used to un-spool the cable, man-lift bucket trucks for the pole-line work and a winch truck to pull the cable from the spools onto the poles.

2.14.5 WIND TURBINE ASSEMBLY AND INSTALLATION

The wind turbines consist of three main components: the towers, the nacelles (machine house) and the rotor blades. Other smaller components include hubs, nose cones, cabling, control panels and tower internal facilities such as lighting, ladders, etc. All turbine components would be delivered to the Project site on flatbed transport trucks and main components would be off-loaded at the individual turbine sites.

Turbine erection is performed in multiple stages including: setting of the bus cabinet and ground control panels on the foundation, erection of the tower (usually in 3-4 sections), erection of the nacelle, assembly and erection of the rotor, connection and termination of the internal cables, and inspection and testing of the electrical system prior to energization.

Turbine assembly and erection involves mainly the use of large truck or track mounted cranes, smaller rough terrain cranes, boom trucks, rough terrain fork-lifts for loading and off-loading materials and equipment, and flat bed and low-boy trucks for transporting materials to site.

In sequence with the installation of component equipment, support systems would be installed, including electrical equipment, control equipment, piping installation, wiring cable, and conduits. Typical construction activities would include mechanical fastening, welding, preparation, and painting.

2.14.6 STARTUP TESTING

At the completion of the construction sequence, each system would be energized and operational testing undertaken. This would include testing of each of the major component systems in a predetermined sequence and completion of QA/QC checks to ensure that each system is ready for full operation. At the end of the startup testing phase, each unit would be separately certified for commercial operation.

2.14.7 PROJECT CONSTRUCTION CLEAN-UP

Since project clean-up generally consists of landscaping and earthwork, it is very weather and season sensitive. Landscaping clean-up is generally completed during the first allowable and suitable weather conditions after all of the heavy construction activities have been completed. Disturbed areas outside of the graveled areas would be reseeded to control erosion by water and wind. To the extent feasible for the Project, cleared areas would be reforested in accordance with typical commercial forestry management practices. All construction clean-up work and permanent erosion control measures would be done in accordance to a SWPPP for the Project as outlined in Section 2.10, Surface Water Runoff.

Other project clean-up activities may include interior finishing of the Operations and Maintenance building, landscaping around the substation area, washing of towers, painting of scratches on towers and exposed bolts as well as other miscellaneous tasks that are part of
normal construction clean-up. Construction clean-up would require the use of a motor grader, dump trucks, front-end loaders, and light trucks for transportation of any waste materials, packaging, etc.
SECTION 2.15 PROTECTION FROM NATURAL HAZARDS  
(WAC 463-60-265)

2.15.1 INTRODUCTION

This section describes conditions that exist on site or measures that are planned as part of the Whistling Ridge Energy Project design to protect the facility from natural hazards.

2.15.2 EARTHQUAKE HAZARD

Earthquake-related damage to industrial facilities, such as the Whistling Ridge Energy Project facility, typically arises from surface fault rupture, liquefaction and lateral spreading of soils, slope failures, or ground shaking. In addition, tsunamis or seiches may impact facilities located near the Pacific Coast or adjacent to other water bodies in seismically active areas. Due to the project site location and elevation, impacts from tsunamis or seiches are not expected to occur.

The Pacific Northwest has four types of seismic sources due to the presence of the Cascadia subduction zone: (1) the subduction zone megathrust, which represents the boundary (interface) between the subducting Juan de Fuca plate and the overriding North American plate; (2) faults located within the Juan de Fuca plate (referred to as the intraplate or intraslab region); (3) crustal faults principally in the North American plate; and (4) volcanic sources beneath the Cascade Range (Wong and Silva 1998). Each of these events has different causes, and therefore produces earthquakes with different characteristics (that is, peak ground accelerations, response spectra, and duration of strong shaking).

Because of their proximity, crustal faults are possibly the most significant seismic sources to inland sites. Studies by Pezzopane (1993) and Geomatrix Consultants (1995) show that at least 70 crustal faults with earthquake potential exist in southwest Washington and northwest Oregon. Many of these faults were unknown or not recognized as being seismogenic a decade ago. Although the largest known crustal earthquake in southwest Washington and western Oregon is only about moment magnitude (Mw) 6 (Wong and Bott 1995), potential exists for events of Mw 6.5 or greater along several recognized faults including the Portland Hills and the recently discovered East Bank faults in Portland and the Gales Creek-Mt. Angel fault zone.

2.15.2.1 Surface Fault Rupture

Coseismic surface rupture occurs when a fault breaks to the land surface during an earthquake. Surface rupture is usually associated with moderate to large earthquakes (magnitude 6.5 or greater) or, rarely during smaller, very shallow events. Surface rupture is highly unlikely at the project site because of the absence of known faults beneath the site and the absence of evidence of historical or geologically recent surface rupture in the project site area. No surface fault movement has been recorded in Washington within historic time (McCrum et al. 1989, Rogers et al. 1996, Lidke et al. 2003). In general, faults that have had a surface rupture during the Holocene epoch (last 10,000 years) or multiple ruptures during the Pleistocene epoch of the Quaternary period (last 10,000 to 1.8 million years) are considered to have a potential for future surface rupture. The known faults with Holocene or late Pleistocene surface displacement within the Puget Sound and Willamette lowlands are distant from the site. No Quaternary faults have
been previously mapped or inferred within the site boundaries (Walsh et al. 1987, Noson et al. 1988, Rogers et al. 1996, Lidke et al. 2003). Due to the lack of recognized Quaternary faults at the project site, the potential for surface fault rupture is considered remote.

### 2.15.2.2 Strong Ground Motion

The southwestern Washington and northwestern Oregon region, in which the project site is situated, is an area of low to moderate historical seismicity but characterized as one of high seismic hazard due to the potential for strong earthquake ground motion (see Section 3.1.3, Seismicity) from regional potential seismic sources. These sources include the Cascadia Subduction Zone (CSZ) located offshore of the west coast of the US, deep intraplate earthquakes beneath the site vicinity within the subducted plate slab, and shallow crustal faults from the Puget Sound and Willamette lowlands and eastward. According to the US Geological Survey (USGS) probabilistic Seismic Hazard Maps published in 2008 (Peterson et al. 2008 and [http://earthquake.usgs.gov/research/hazmaps/](http://earthquake.usgs.gov/research/hazmaps/)), the estimated peak ground acceleration for the site is on the order of 0.18g for a 475-year return period earthquake (10 percent chance of being exceeded in 50 years). For a 2,475-year return period earthquake (2 percent of being exceeded in 50 years), the estimated peak acceleration for the site is on the order of 0.40g. Design of facilities for the USGS estimated levels and potentially higher levels of ground shaking can be accommodated within the current level of earthquake engineering design practice and applicable building codes.

### 2.15.2.3 Liquefaction and Lateral Spreading

Liquefaction is a phenomenon whereby soils undergo significant loss of strength and stiffness when they are subjected to vibration or large cyclic ground motions produced by earthquakes. Typically, cyclic loading of saturated soils leads to the buildup of excess pore-water pressure as a result of soil particles being rearranged with a tendency toward denser packing. Under undrained conditions (such as during earthquake shaking), loads are transferred from the soil skeleton to the pore-water with consequent reduction in the soils’ shear strength.

Saturated granular soils without cohesive fines (i.e., gravels, sands, and silts) are most susceptible to liquefaction. Other factors affecting the potential for liquefaction in soils are density, amplitude of loading, confining pressure, past stress history, age of soil deposit, the size, shape and gradation of particles, and the soil fabric structure. Liquefaction-induced ground settlement and lateral spreading have been the primary cause for extensive damage to aboveground structures, foundations, and pipelines during many earthquakes.

Test pits excavated at the project site encountered shallow bedrock covered with a combination of cohesive and cohesionless soil. No groundwater was observed in any of the test pits. Based on the soils encountered during the field explorations, it is URS’s opinion that the potential for liquefaction at this site is very low.

The risk of seismically induced settlement and lateral spreading is low due to the low liquefaction potential. It is URS’s opinion that settlements and lateral spread induced by a seismic event would be minimal. If, during additional subsurface investigations at the site, liquefiable soils and high groundwater are observed, design of the facilities can be
accommodated within the current level of earthquake engineering design practice and applicable building codes.

2.15.2.4 Tsunamis and Seiches

Tsunami waves may enter the Columbia River from distant circum-Pacific earthquakes, local offshore earthquakes on the CSZ, or submarine landslides in the adjacent Pacific Ocean offshore area. The project site is located on a series of north-trending ridges that range in elevation from approximately 2,100 to 2,300 feet above msl and would be above the area potentially affected by a tsunami wave.

Although seiches have been observed in the Pacific Northwest during the 1949 Queen Charlotte Islands, Canada, and the 1964 and 2002 Alaskan earthquake of approximately $M_w$ 8 or greater, seiches have not been reported in the Columbia River, except in the reservoir directly behind the Grand Coulee Dam farther upstream. In our judgment, the seiche potential in this river near the site is minimal, and, due to the elevation of the site, the potential for damage from any seiche that might occur is considered to be remote.

2.15.2.5 Mitigation Measures for Earthquake Hazards

All structures on the site would be built in accordance with the seismic design provisions presented in the 2006 version of the International Building Code (IBC), and the American Society of Civil Engineers 07-05 standard. The site soil is best represented as Stiff Soil (Soil Site Class D). Based on the site location and site conditions described above, we recommend that the values listed in Table 2.15-1 be used for seismic design of the project in accordance with Section 1613.5.3 of the 2006 IBC. The occupancy category of the proposed structure is assumed III as per Section 1613.5.6 of the 2006 IBC.

a. Assumes Seismic Use Group III

A visual inspection would be conducted following abnormal seismic activity. These inspections would look for signs of incipient mass movement in those areas identified as potentially susceptible to such failures.
2.15.3 SLOPE FAILURE AND MASS WASTING

Pursuant to Skamania County Code (SCC) Title 21A, Chapter 21A.06 - Landslide Hazard Areas, URS has conducted a preliminary landslide hazard evaluation of the proposed Whistling Ridge Energy Project wind turbine site. The project location is shown in Figure 3.1-1, Site Geology.

A URS Licensed Engineering Geologist conducted a site-specific landslide hazard investigation. The investigation consisted of:

- Review of Sections of the County Code that address Geologically Hazardous Areas
- Review of existing available topographic, geologic and soils literature and maps
- Analysis of project-specific stereo aerial photographs
- Review of project test pit logs and soil samples
- A one day site reconnaissance

According to the County Code, the primary criteria for landslide hazard designations are: presence of pre-existing, known mappable landslides; slope angle; and/or composition of the near-surface soils or rock.

URS has created a color-coded map of the study area using an existing USGS 10 meter digital terrain model (DTM) to segregate slopes into three categories: slopes less than 20%; slopes between 20% and 30%; and slopes greater than 30%. We then superimposed the Natural Resources Conservation Services (NRCS) soil survey map onto the slope map to provide soil type information. The resulting Landslide Hazard Map is presented herein as Figure 2.15-1.

2.15.3.1 Landslide Hazard Area Delineation

Skamania County recognizes three classes of landslide hazard areas (LHAs). Class I (Severe) LHAs are considered to present a severe landslide hazard and are distinguished as areas of known mappable landslide deposits which have been designated landslide hazard areas by the local legislative body. Class II (High) LHAs are areas with slopes between twenty and thirty percent that are underlain by soils that consist largely of silt, clay or bedrock, and all areas with slopes greater than thirty percent. Class III (Moderate) LHAs are areas with slopes between twenty percent and thirty percent not included in Class II.
URS reviewed available geologic and soils literature to develop a landslide hazard classification for the proposed Whistling Ridge Energy Project. An existing published regional geologic map (partially recreated in Figure 3.1-1 of this report) indicates a large landslide in the northeast corner of the study area underlying Tower Line C. Review of stereo photographs of the area where the landslide deposits are mapped, coupled with a site reconnaissance, indicate that there is little geomorphic evidence for landslide activity such as obvious scarps, hummocky or benchend terrain, lobate toe areas, or redirected watercourses. No deep subsurface investigations have been carried out at the site to date, but future explorations in support of design for the turbine tower foundations would provide subsurface information regarding the presence of landslide deposits in the area. Based on our preliminary investigation, there does not appear to be any area of the site that meets Skamania County’s criteria for a Class 1 LHA.

Class II LHAs are shown in green on Figure 2.15-1. The Class II LHAs at the site are predominantly associated with the steep slopes to the west of proposed Tower Lines A and B. There are also steep slopes east of the seven southernmost Tower Line A towers, and on both sides of Tower Line C.

### 2.15.3.2 Impacts

Although none of the proposed turbines are located within Class II LHAs, several of the towers along the western side of the project site (Tower Lines A and B) are located along ridgelines with descending slopes that are locally greater than 35 degrees (70%). The heads of some of the drainages along these slopes are arcuate, indicating possible mass wasting activity such as landslides, debris flows, and/or earthflows.

Based on aerial photo and field observations, the primary mass wasting process below the ridgelines appears to be debris flows and soil creep. No evidence for deep-seated, block failure type landslides was observed. Local surficial creep of near-surface soils is indicated by the presence of pistol-butted trees on some of the slopes, primarily on the descending slope west of the northern portion of Tower Line A. Other slopes have mature conifer stands that indicated little or no soil creep. Further subsurface investigation in support of final tower foundation design would help determine if there are weak rock or soil layers that could contribute to more deep-seated failure of the ridges and provide information on the quality of the rock mass underlying the ridgelines.

It appears that the primary concern for towers located adjacent to the Class II LHAs is the potential for headward erosion of the steep drainages by debris or earth flow processes. Erosion rates of these drainages are unknown, but no obvious recent mass wasting features were observed in the aerial photos or during the site reconnaissance.

Class III LHAs have been delineated adjacent to proposed wind turbines along the southern Tower Line A, and Tower Line C. Class III LHAs are not anticipated to have any impact on the proposed facilities, due to the robust nature of the proposed foundation designs.

The Landslide Hazard Evaluation identified several areas where the proposed wind turbine generators are located adjacent to slopes that meet Skamania County’s criteria for Class II and Class III Landslide Hazard Areas. The primary hazard to the proposed towers appears to be the
potential for exposure to headward erosion of steep drainages on the slopes below some of the
tower locations. Exposure of the towers to headward erosion of the steep slope drainages can be
minimized by providing maximum possible setbacks from the tops of the steep slopes and/or by
siting the turbines along portions of the ridgelines that are above intervening spur ridges. The
most critical area of exposure to Class II LHAs is the narrow ridge at the southern portion of
Tower Line A.

It is URS’s opinion that the proposed project can be constructed and operated without danger to
human life or the surrounding environment due to landslide hazards.

2.15.3.3 Mitigation Measures

No mitigation measures are required.

2.15.4 VOLCANIC ERUPTION

The Cascade Mountains of the Pacific Northwest region contain sixteen major volcanoes which
extend from Mount Garibaldi in British Columbia to Lassen Peak in California (Harris 1988).
Four of the volcanoes within Washington and Oregon have experienced activity within historic
time: Mount Baker, Mount Rainier, Mount Hood, and Mount St. Helens. Mount Adams is the
closest volcano to the project site, situated approximately 30 miles due north, but is not
historically active. Mount St. Helens is the closest historically active volcano to the project site,
situated approximately 42 miles to the northwest (see Figure 2.15-2).

Effects of volcanic activity may include lava flows, mudflows, pyroclastic flows, and ash-fall.
Volcanic flows are typically limited to the flanks of the volcano and major drainage channels
extending from the volcano. The USGS has estimated the areas most likely to be affected by
future eruptions of Mount St. Helens. The site is not situated in an area identified as having a
potential hazard from a pyroclastic flow or lahar (Wolfe and Pierson 1995). Of greatest impact
in terms of area affected by an eruption is the tephra, or ash, carried aloft that subsequently falls
to the land surface. Modern meteorological records show that both high altitude wind directions
and speeds in Washington have been more prevalent and stronger toward east than toward the
west in the site region. The USGS (Wolfe and Pierson 1995) estimates that there is between a
0.02% and 0.1% annual probability that there would be 4 inches (10 cm) or more of ash
deposited at the site from eruptions throughout the Cascade Range (Figure 2.15-2). Therefore,
no mitigation measures are proposed for direct volcanic hazards.

Secondary processes associated with volcanic eruption, such as lahars, flooding and sediment
loading can result in more serious damage. The Whistling Ridge Energy Project site is not
located within the modern floodplain of rivers within the watershed of Mt. St. Helens or Mount
Adams.
Annual probability of accumulation of ten or more centimeters (four or more inches) of tephra in Washington and Oregon from eruptions throughout the Cascade Range. Probability distribution reflects the frequency of explosive eruptions at each major Cascade volcano, the variability in the thickness of tephra that could be deposited at various downwind distances, and the variability in wind direction.

SOURCE: Wolfe and Pierson, 1995
In the event that a volcanic eruption would damage or impact project facilities, the project facilities would be shut down until safe operating conditions return. If an eruption occurred during construction, a temporary shut-down would most likely be required to protect human health and equipment.

2.15.5 FLOODING

The Whistling Ridge Energy Project site is not located within any 100-year floodplains as currently mapped by the Federal Emergency Management Agency (FEMA). The current elevation of the site is above the 100-year floodplain of the Little White Salmon and Columbia Rivers, and mitigation measures for flooding are not planned.
SECTION 2.16 SECURITY CONCERNS  
(WAC 463-60-275)

2.16.1 SECURITY PLAN

The Whistling Ridge Energy Project site is located on private land approximately 7 miles northwest of the City of White Salmon in Skamania County, Washington. The project would consist of a substation, an Operations and Maintenance building, and graveled site access roads which lead to the wind turbines. Security is primarily a function of controlled access to the project site and lock-out provisions to major equipment and controls.

A thorough review with WindPro Insurance of Palm Desert, CA, a major insurer of wind power projects around the world, found no recorded cases of terrorism, sabotage, or other similar security threats in the past 15 years of their knowledge for more than 17,000 wind turbines operating in 14 different countries. Vandalism has occurred on some wind power projects, which generally has been limited to petty theft of tools and/or equipment.

A full time security plan would be implemented during project construction. Once construction is completed, a comprehensive operations security plan would be prepared along with a detailed emergency plan.

2.16.1.1 Construction Phase

The Site Project Manager would work with a security contractor to develop a plan to effectively monitor the overall site during construction including drive-around security and specific checkpoints. The security inspection and monitoring plan would be changed throughout the course of construction based on the level of construction activity and amount of sensitive or vulnerable equipment and materials in specific area. Much of the security monitoring activities would be straightforward since all site access ways would be accessible from private logging roads.

Security

All site staff and subcontractors would be required to wear an identity badge and display vehicle clearance tags at all times. Newcomers to the project site would be required to check in, log in, and log out at the main site construction trailers. The main site construction trailers would be equipped with outdoor lighting and motion sensor lighting as required.

Parking for the construction contractor employees would be in an assigned parking area. A barrier or other device would be erected around protected areas to exclude vehicles and pedestrians until protection is no longer required.

Secured Lay-Down Areas

Construction materials would be stored at the individual turbines locations, or at the lay-down area around the perimeter of the Operations and Maintenance facility and site construction trailers. Temporary fencing with a locked gate would be installed for a roughly 1.5-acre area adjacent to the site trailers for the temporary storage of any special equipment or materials. After construction is
completed, the temporary fencing would be removed and the area re-seeded with an appropriate seed mix.

2.16.1.2 Operation Phase

Site visitors including vendor equipment personnel, maintenance contractors, material suppliers and all other third parties would be required to obtain permission for access from authorized Whistling Ridge Energy Project staff prior to entrance. The Plant Operations Manager, or designee, would grant access to any critical areas of the site on an as-needed basis.

Access ways to the main Operations and Maintenance facility area, site trailers, and all wind turbine roads would be constructed with lockable access gates. The access gates would be open during working hours and be secured by project site security personnel after working hours.

Both the Operations and Maintenance facility and the main substation would be equipped with outdoor lighting and motion sensor lighting. The substation would be surrounded by an eight-foot-tall chain-link fence with razor wire along the top. All wind turbines, pad transformers, pad mounted switch panels and other outdoor facilities would have secure, lockable doors.

The plant operations group would prepare a detailed security plan to be implemented to protect the security of the project and project personnel.

2.16.2 EMERGENCY RESPONSE PLAN

Whistling Ridge Energy LLC would establish an emergency response plan for the plant to ensure employee safety from the following emergencies: on-site chemical release, medical emergency, major power loss, fire, extreme weather, earthquake, volcano, and bomb threat. The plan would be established prior to completion of construction. The plan would follow the requirements of WAC 296-24-567 and 296-62-3112 and 29 Code of Federal Regulations (CFR) 1910.38, Emergency Action Plan. All hourly and salaried employees, including administrative staff as well as contractors and visitors, would be covered by the plan. The Emergency Response Plan would be administered by the Plant Manager who would be responsible for overall coordination of the plan. See Section 4.1.6, Emergency Response Plans.

The plan elements would include:

- General evacuation
- Downed power system hazards with specific attention to power lines and the substation
- Personnel injury
- Uptower rescue
- Construction emergencies
- Fire/explosion on-site
• Natural gas release off-site
• Chemical release
• Oil release
• Tornado
• Earthquake
• Emergency freeze protection
• Volcanic eruption (ashfall)
• Injury
• Facility blackout
• Facility bomb threat
SECTION 2.17 STUDY SCHEDULES  
(WAC 463-60-285)

2.17.1 INTRODUCTION

Surveys of the project site have been completed in full consultation with wildlife agencies. Habitat areas have been fully mapped and included in this Application. Additional surveys are planned for northern goshawks and bats to augment information already obtained, as described in Section 2.17.2. Subsequent to the March 2009 submittal of the Application for Site Certification, additional surveys were performed for the roadway corridor within the Columbia River Gorge National Scenic Area in the spring of 2009, and existing surveys will be confirmed. All will be included in the information prepared for the environmental impact statement.

2.17.2 ADDITIONAL STUDIES

Additional northern goshawk and anabat surveys will be made in the project area:

- The northern goshawk is not listed as “threatened” or “endangered” by either the state of Washington or federal agencies. The applicant completed northern goshawk surveys in accordance with protocols accepted and recommended by the Washington Department of Fish & Wildlife (WDFW). The surveys were conducted during the relevant seasons in 2004, 2005, 2008 and again in 2008 spring and summer, 2009, in accordance with agreed upon protocols. No goshawks were found on the project site, nor were any observed on any surrounding properties. It is highly unlikely that goshawks will be found on the project site or in areas to the north, owned and managed by Washington State Department of Natural Resources (WDNR). The applicant will conduct an additional survey on the project site in spring 2009 to confirm these findings, in accordance with agreed protocols. The WDNR property near the project site has similar habitat characteristics to the project site, and was recently logged. While no goshawks are expected on the area to the north, due to the proximity of turbines to the WDNR property to the north, the Applicant will conduct an intensive survey effort on approximately 360 acres to the north of the project site to confirm that the project does not present any significant impact to this species.

- Anabat detection surveys proposed for 2009 were started in July and will be implemented through the months of July continue through October, and will augment our understanding of bat activity within the vicinity of the proposed micrositing corridors. Anabat detectors also will be elevated to gain a better understanding of bat activity at rotor swept height.

The access roadway has been revised to use West Pit Road, that would traverse the Scenic Area is an existing road in a developed area managed for commercial forestry that connects the project area to the Cook-Underwood Road (via Willard Road), entirely outside of the Columbia River Gorge National Scenic Area. The roadway would be widened to provide access for construction vehicles. The following Plant and wildlife surveys are planned for were performed in June--spring 2009 and the results have been incorporated into this amended application.
• Scenic Area Wetland and Habitat Survey
• Scenic Area Sensitive Plant Field Survey
• Scenic Area Wildlife Survey
• Scenic Area Cultural Resource Reconnaissance Survey
SECTION 2.18 POTENTIAL FOR FUTURE ACTIVITIES AT THE SITE  
(WAC 463-60-295)

2.18.1 EXPANSION OF WHISTLING RIDGE ENERGY PROJECT

Depending on market conditions and the ability to lease land from the WDNR, there is a potential that the Whistling Ridge Energy Project could be expanded in the future. The potential expansion area would be directly north of the existing project site and consist of the lease of up to four sections\(^1\) from WDNR for the placement of approximately 50 additional wind turbines. The potential expansion would be located in Klickitat County in an area studied during that County’s Energy Overlay Zone process. See Figure 2.18-1, Potential Expansion Area.

At this time, such expansion is speculative, and sufficient environmental and engineering information and analyses are not available to pursue permitting. If the project is ultimately expanded to include the WDNR property, revenues generated from these lands would benefit the State School Trust, including local public schools.

The expanded site and the existing and planned facilities (both the transmission and the Operations and Maintenance facilities) would support an expansion in the future, should the expected demand for clean renewable energy continue to grow.

\(^{1}\) A “section” is one square mile, consisting of 640 acres.
SECTION 2.19 ANALYSIS OF ALTERNATIVES
(WAC-463-60-645)

2.19.1 INTRODUCTION

This section summarizes the alternatives that were explored during the development of the Whistling Ridge Energy Project.

2.19.2 SITE SELECTION

The Whistling Ridge Energy Project would be a wind-powered energy facility constructed by Whistling Ridge Energy LLC. Whistling Ridge Energy LLC is a special-purpose corporation formed to develop, permit, finance, construct, own and operate the Whistling Ridge Energy Project. Whistling Ridge Energy LLC is a Washington corporation formed under Title 23B of the RCW. It is wholly-owned by S.D.S Co., LLC and proposed to be constructed on land owned by S.D.S. Co., LLC and Broughton Lumber Company. The project site, north of the Columbia River Gorge, is optimally suited for wind energy, and is crossed by two BPA high voltage transmission lines. The project site already has a network of logging roads, requiring the construction of relatively few new roads. Approximately 7.27.9 miles of existing private logging roads would be improved. In areas where there are no existing logging roads near proposed wind turbine strings, approximately 2.4 miles of new gravel access roads would be constructed. Some of these construction roads would continue to be used during the project’s operational phase.

As described in the Introduction, the objective of the Whistling Ridge Energy Project is to construct and operate a wind energy generation resource to meet a portion of the projected growing regional demand for new energy resources. The Energy Information Administration projects total electricity demand growth between 1.8% and 1.9% per year from 2001 through 2025. The Western Electricity Coordinating Council forecasts that, due to cooler than normal temperatures, peak demand requirement will increase at a compound rate of 2.4% per year (WECC 2005). Based on data published by the Northwest Power and Conservation Council, electricity demand for the Council’s four-state Pacific Northwest planning region (Washington, Oregon, Idaho, and Montana) was 20,080 average MW in 2000 and is estimated to grow to 22,105 average MW by 2015, based on medium demand (NWPCPC 2005). The Northwest Power and Conservation Council’s Sixth Electric Power and Conservation Plan is expected to be published in draft in August 2009.

Washington and the Northwest region face a growing medium and long-term demand for power. Many regional utilities are seeking to acquire new generating resources to meet their loads. More specifically, several regional utilities, including Avista, Puget Sound Energy, and PacifiCorp (doing business as Pacific Power in Washington) have all completed detailed studies and demand forecasts of their own systems as part of their Integrated Resource Plan or Least Cost Plan process with oversight from the Washington Utilities and Transportation Commission. As a result of their formal Integrated Resource Plan or Least Cost Plan processes, these three utilities have issued Requests for Proposals specifically for wind power and/or other renewable
resources. Finally, Washington now requires that utilities meet the state’s Renewable Portfolio Standards requirements, which will likely be confirmed nationally.

The proposed project is intended to help meet this growing regional demand for renewable, wind-generated electricity.

The project is not considered a reasonable alternative to any other wind energy facility or wind energy facility site. No project, on its own, can meet the forecasted or immediately requested demand for power in the region.

EFSEC has previously supported the application of certain criteria for the evaluation of wind energy project sites. While Whistling Ridge Energy LLC is not a developer of multiple sites, and only proposes the site described in this application, the selection of this site conforms to accepted site selection criteria:

- Commercially viable wind resource
- Access to high voltage (115kV or 230 kV) transmission lines within a reasonable distance to a project site, with sufficient available capacity to carry the project’s output
- Absence of significant environmental constraints (i.e., no threatened or endangered species, major archeological resources, critical wetlands, etc.)
- Willing landowner(s) with sufficient undivided acreage to support a project
- Accessible site with sufficient road access to permit delivery of large wind turbine components and allow construction of project infrastructure
- Appropriate and compatible zoning designation and/or lack of conflicting land uses

The Whistling Ridge Energy Project site appears to meet all of the above criteria. Other potential sites are not owned and controlled by the Applicant, and they are not deemed to be viable alternatives to the proposed project. Because the site is optimally suited for the production of wind energy, has been used for forestry, has existing roads suitable for wind turbine placement and maintenance, is adjacent to BPA transmission lines, and is owned by the Applicant, no additional sites were considered.

2.19.3 ELECTRICAL TRANSMISSION ROUTING ALTERNATIVES

The project site is crossed by two BPA high voltage transmission lines. A substation with a 230 kW overhead line is proposed to be located immediately adjacent to the BPA right-of-way. The proposed location of the substation was selected to be placed in a relatively clear and low level area adjacent to the planned Operations and Maintenance facility. The elevation was selected to minimize impacts from winter snow. To minimize the need for creating new transmission corridors, no alternative transmission routing corridors were considered.
2.19.4 ALTERNATIVE TECHNOLOGIES AND FUEL

Whistling Ridge Energy LLC has proposed the project to provide an alternative source of energy that does not generate air or water emissions and does not produce hazardous waste. Wind energy is considered a renewable resource, and its operation does not deplete natural resources such as coal, oil, or gas; cause environmental damage through resource extraction and transportation; or require significant amounts of water during operation. Because of the environmental benefits of wind energy, and the suitability of the site already owned by the Applicant for wind energy, no alternative technologies or fuel sources were considered.

2.19.5 ALTERNATIVE CONSTRUCTION ACCESS

There are only two potential ways to access the project site. Both are via County roads from SR 14 to Cook-Underwood Road. From Cook-Underwood Road the project site can either be accessed by:

- **Route 1**: Ausplund Road to a private logging road vacated by Skamania County in 1987, which crosses private property (not owned by the Applicant) that is currently used for residential, agricultural orchards, and commercial timber production and harvest.

- **Route 2**: Kollock-Knapp Road to Scoggins Road to a private logging road called the CG2930 road on County Assessor’s maps, which crosses property owned by the Applicant that is currently used for commercial timber production and harvest. (See Figures 4.3-1 and 4.3-2 in Section 4.3 Transportation for the location of CG2930.)

- **Route 3**: Cook-Underwood Road to Willard Road to a new connection to West Pit Road. West Pit Road is a private logging road that is currently used for commercial timber production and harvest. (See Figures 4.3-1 and 4.3-2 in Section 4.3 Transportation for the location of West Pit Road.)

The private logging road in Route 1 was made a County right of way in 1923. It was vacated for public use in 1987 by resolution of the Skamania Board of County Commissioners; however, the rights to use the road by abutting property owners remain. Additionally, road improvements to this route would be required for access to construct the wind energy facility and for ongoing Operations and Maintenance traffic. Impacts to a non-project landowner from these activities would occur if Route 1 were used.

Route 2, on the other hand, would require minor roadway improvements that would not directly impact any non-project landowners. However, these roadway improvements would require construction within the Columbia River Gorge National Scenic Area (CRGNSA). Therefore, Route 2 is the preferred, and perhaps the only practicable, access alternative.

Route 3 would require a new direct connection from Willard Road to West Pit Road, and improvements to the West Pit Road. The roadway is located entirely on private property outside of the CRGNSA. Route 3 is the preferred, and perhaps only practicable, access alternative.
2.19.6 ALTERNATIVE HAUL ROUTES AND METHODS OF TRANSPORT

All wind energy components, including tower sections, the nacelle and turbines, and blades would be shipped to either the Port of Longview or Port of Vancouver and then be transported by any or all of the following three modes of travel:

- Specialized trucks along State, County, City, and private roadways
- Burlington Northern Santa Fe (BNSF) rail lines running parallel to SR 14
- Barge and tug boat up the Columbia River and through the lockage facility at the Bonneville Dam to the SDS Lumber Company industrial dock in Bingen

Wind energy components transported on specialized trucks from either of the Ports would be delivered directly to the proposed project site. Components transported either by rail or barge from either of the Ports could be delivered to the SDS Lumber Company industrial facility in Bingen, loaded onto specialized trucks, and then transported to the proposed project site. Fuel would be delivered to the proposed site by truck as needed.

Trucks transporting wind energy components could have loads as high as 17.5 feet measured from the ground to the highest point of the load, as wide as 14.5 feet or as long as 150 feet. Specialized trucks may be used to transport wind energy components from either the Port of Longview or the Port of Vancouver to the west junction of Cook-Underwood Road with SR 14 at MP 56.28. East of that intersection trucks traveling along SR 14 between Vancouver, Washington and Cook-Underwood Road would be physically constrained by a series of three very narrow tunnels with height restrictions as low as 13 feet 9 inches measured vertically from the edge of the roadway. Over-size loads that would include transport of the tower sections, the nacelles and turbines, and blades would encounter restrictions and/or prohibitions along SR 14 between Vancouver, Washington and the junction of SR 14 and Cook-Underwood Road at MP 63.3256.28 due to the length and/or width of the loads. Cook-Underwood Road near its northern most point at approximate MP 5.5 contains a bridge that crosses the Little White Salmon River. Crossing this bridge with specialized trucks transporting wind energy components would require special provisions agreed upon between S.D.S Co., LLC and Skamania County.

An alternate route for transport of wind energy components from either of the Ports to the east junction of SR 14 and Cook-Underwood Road at MP 63.32 would include trucks traveling on Interstate 84 (I-84) through Oregon to the Boardman junction, then along SR 730 to the junction of I-82 with SR 395, across the Columbia River back into Washington State, and then to SR 14. Trucks traveling on SR 14 between the junction of I-82/SR 395 and Cook-Underwood Road would be physically constrained by one very narrow tunnel with a height restriction of 13 feet 3 inches measured vertically from the edge of the roadway.

The option of using rail to transport the wind energy components from either of the Ports to the SDS Lumber Company facility also was analyzed. Wind energy components on rail cars can be up to 14.5 feet in width, up to approximately 15 feet in height, and as long as 150 feet. The BNSF rail line between Vancouver, Washington and the SDS Lumber Company facility in Bingen, Washington may not be able to accommodate loads with widths in excess of 14 feet.
This may preclude transport of the bottom tower sections using rail. The wind energy nacelles, turbines, and blades could be transported along the BNSF line to the SDS Lumber Company facility. BNSF could transport the wind energy components on standard or heavy-duty 89-foot long flat rail cars. The wind energy components would be off-loaded at the SDS Lumber Company industrial facility to a staging location to be determined and loaded onto specialized trucks for transport to the proposed project site. Transport of wind energy components using specialized trucks from the SDS Lumber Company industrial facility to SR 14 would require the use of Maple Street in the City of Bingen, Washington for approximately 0.25 mile.

The third option analyzed for transporting the wind energy components from either of the Ports to the SDS Lumber Company industrial facility was by using barges. The wind energy components would be off-loaded from a ship at either of the Ports, loaded onto barges, and then transported upriver to the Bonneville Dam using tug boats. The barges and tugs would by-pass the Bonneville Dam via the lockage facility, and continue upriver to the SDS Lumber Company industrial facility. There would be no over-size or over-weight restrictions using barges as a transport mode for wind energy components at either of the Ports, on the Columbia River, or at the lockage facility at the Bonneville Dam. Coordination with the Bonneville Dam Project Office would be required to determine optimal times for lockage use. The Bonneville lockage facility accommodates commercial, government, and recreational vessels. The heaviest lockage traffic on average occurs during the month of August. Vessel traffic is typically heaviest on Thursdays, Fridays, Saturdays, and Sundays. The wind energy components would be off-loaded at the SDS Lumber Company industrial facility to a staging location to be determined and loaded onto specialized trucks for transport to the proposed project site. Transport of wind energy components using specialized trucks from the SDS Lumber Company industrial facility to SR 14 would require the use of Maple Street in the City of Bingen, Washington for approximately 0.25 mile. There are currently no over-size or over-weight restrictions for this roadway. Like the use of rail, this option would still require using specialized trucks to transport the wind energy blades from the SDS Lumber Company industrial facility to the junction of SR 14 and Cook-Underwood Road at milepost (MP) 63.32, and this section of SR 14 has a length restriction of 125 feet.

In Section 4.3 Transportation, there is a detailed description of the limitations on area roadways in terms of the width, height, length and weight of the loads to be transported, and the needed roadway improvements.

**2.19.7 ALTERNATIVE SITE FOR OPERATIONS AND MAINTENANCE FACILITY**

Two sites are being considered for the operations and maintenance facility, either adjacent to the substation on site or along West Pit Road to the west of the project site. Both sites would be approximately 5 acres in size and include an approximately 3,000 square foot enclosed space, including office and workshop areas, a kitchen, bathroom, shower and utility sink. The building would be constructed of sheet metal, and would be approximately 16 feet tall (to the rook peak). The site along West Pit Road provides the advantage of being at a lower elevation than the site adjacent to the substation which would make it more accessible during winter months. The West Pit site is located on land zoned Residential 5, whereas the alternative site is Unmapped (UNM).
The maintenance and operations use would be allowed by conditional use approval in the Residential 5 zone and is allowed outright in the UNM area.

2.19.7 2.19.8 NO ACTION ALTERNATIVE

Under the No Action Alternative, the proposed Whistling Ridge Energy Project would not be constructed or operated, and the environmental impacts described in this Application would not occur. The No Action Alternative assumes that future development would comply with existing zoning requirements for the project area, which include Unmapped, Forest/Agriculture 20 and Residential 10. The project area is designated in the County’s Comprehensive Plan as “Conservancy.” According to the County’s Comprehensive Plan, the Conservancy land use is intended to provide for the conservation and management of existing natural resources in order to achieve a sustained yield of these resources, and to conserve wildlife resources and habitats (Skamania County 2007). Logging, timber management, agricultural and mineral extraction are the main activities that take place in this area. Among the uses identified in the 2007 Comprehensive Plan as appropriate in the Conservancy designation are: public facilities, utilities, utility substations, forest management (including temporary logging and mining camps) and surface mining (by conditional use). Wind energy is considered to be a utility and could be proposed by another applicant.

If the proposed project is not constructed, Washington electrical utilities would lose an important non-polluting renewable resource alternative close to the region’s major metropolitan areas. The economic benefits associated with this capital investment and the economic activity associated with construction and operation of the facility would be foregone.

It is likely that the region’s need for power would be addressed by some combination of user-end energy efficiency and conservation measures, by existing power generation sources, or by the development of new renewable and non-renewable generation sources. Base load demand would likely be filled through the expansion of existing thermal generation or development of new thermal generation, such as gas-fired combustion turbine technology. Such development could occur at appropriate locations throughout the state of Washington.

A base load natural gas-fired combustion turbine would have to generate approximately 41 average MW of energy to replace an equivalent amount of power generated by the project (75 MW at 33% net capacity). An average MW (aMW) is the average amount of energy supplied over a specified period of time, in contrast to MW, which is the maximum or peak output or capacity that can be supplied for a short period.
SECTION 2.20 PERTINENT FEDERAL, STATE AND LOCAL REQUIREMENTS
(WAC 463-60-297)

2.20.1 APPLICABLE FEDERAL, STATE AND LOCAL PERMIT REQUIREMENTS

Table 2.20-1 lists all applicable federal, state, and local permits and related requirements that would apply to construction of the Whistling Ridge Energy Project if Whistling Ridge Energy LLC had not elected to request approval under EFSEC jurisdiction. The table lists the permits or requirements, identifies the permitting agency, and cites the authorizing statute or regulation. The table also identifies the section(s) in the application relating to each permit or requirement.

### 2.20.2 FEDERAL PERMITS

#### 2.20.2.1 National Environmental Policy Act (NEPA)

Due to the interconnect with the BPA system, and the need for a Large Generator Interconnection Agreement, the project must undergo National Environmental Policy Act (NEPA) review. The Applicant anticipates that BPA and EFSEC will be jointly preparing a joint NEPA/SEPA process. Environmental Impact Statement.

**Interconnection Agreement**

The Applicant filed for an interconnection on June 2002 and it is presently under study.

#### 2.20.2.2 Threatened or Endangered Species Assessments

*National Environmental Policy Act (federal) lead agency*

**Endangered Species Act, § 7; 16 U.S.C. § 1531 et seq.; 50 CFR Pt 402**

The Endangered Species Act (ESA) provides for the conservation of endangered and threatened species and the ecosystems upon which they depend. The ESA establishes, for federal agency actions, a “procedural obligation to consult” with the US Fish and Wildlife Service (USFWS) or the National Marine Fisheries Service (NMFS).

The consultation process generally involves three steps. First, a federal agency proposing to take action inquires with USFWS and NMFS as to whether a protected species may be present in the area affected by the project. Second, if there is reason to believe the federal action will likely affect a protected species the agency must consult with USFWS and NMFS and avoid jeopardizing the species. The agency prepares a Biological Assessment to determine whether the species (if present) or its habitat would likely be affected by the action. USFWS and NMFS will review the Biological Assessment for completeness and determine whether the federal action will jeopardize the species or not, and will suggest alternatives to reduce or eliminate impacts of the action on the species.

With regard to potential mortalities to avian species, under the Migratory Bird Treaty Act, the USFWS has jurisdiction over the taking of migratory birds. The applicability of the Migratory Bird Treaty Act to wind energy facilities has been debated. However, enforcement under the Migratory Bird Treaty Act has not been initiated for projects like this one that have undergone extensive pre-
application avian survey work, have conferred with wildlife agencies, and can show that potential impacts are insignificant through sound protocols and efforts to minimize and mitigate impacts, including through compliance with voluntary wind energy siting guidelines.

**Compliance Plan**

The Applicant has completed extensive pre-application habitat and wildlife surveys, conducted pursuant to best industry standards, in consultation with wildlife agencies. A Biological Assessment will be prepared and consultation initiated with the USFWS concurrent with the preparation of the NEPA/SEPA EIS. Compliance is further documented in Section 3.4 Habitat, Vegetation, Fish and Wildlife.

### 2.20.2.3 Historic Preservation/Landmark Review

*National Environmental Policy Act (federal) lead agency (OFE)*

The National Historic Preservation Act authorizes the Secretary of the Interior to expand and maintain a National Register of districts, sites, buildings, structures, and objects significant in American history, architecture, archeology, engineering and culture. Federal agencies having authority to license any undertaking must, prior to approval of funds or issuance of any license, take into account the effect of the undertaking on any district, site, building, structure or object that is included in, or eligible for, inclusion in the National Register.

The purpose of the Natural Landmarks program is to identify and encourage the preservation of nationally significant examples of the full range of ecological and geological features that constitute the nation’s natural heritage. Federal agencies are responsible for considering the existence and location of natural landmarks when assessing the effects of their actions on the environment pursuant to NEPA.

**Compliance Plan**

A survey for potential historic sites has been prepared and a new survey will be performed and included in the EIS. No evidence of prehistoric activity was observed during the cultural resource survey. No archaeological sites or historic properties were identified, although two historic archaeological isolates were found and documented (Section 4.2.5, Historic and Cultural Preservation). Federal and state regulations require consideration of project effects on historic and/or cultural resources. Cultural resources must undergo a Section 106 Review Process for projects with a federal nexus under the National Historic Preservation Act. Section 106 review will be included in an EIS as a part of the NEPA compliance documentation.

### 2.20.2.4 No Hazard Determination

Pursuant to Title 14 of the CFR, Part 77 Objects Affecting Navigable Airspace, notice shall be made to the FAA of any construction of more than 200 feet above the ground level at its site. The wind
turbines, estimated at approximately 426 feet in height (262-foot hub height and 164-foot radius blades, measured from the ground to the turbine blade tip), would exceed the 200-foot measure. If a structure exceeds obstruction standards but does not result in a substantial adverse effect, a determination of no hazard would be required to be obtained from FAA prior to construction.

**Compliance Plan**

Whistling Ridge Energy LLC will send one executed form set (four copies) of FAA Form 7460-1, Notice of Proposed Construction or Alteration, to the Manager, Air Traffic Division, FAA Regional Office having jurisdiction over the area within which the construction or alteration will be located. The notice required under Sec. 77.13(a) (1) through (4) will be submitted at least 30 days before the earlier of the following dates: (1) the date the proposed construction or alteration is to begin; or (2) the date an application for a construction permit is to be filed.

All no hazard determinations shall address or include:

1. **Full Description.** A full description of the structure, project, etc., including all submitted frequencies and effective radiated power shall be included. Use exact information to clearly identify the nature of the project (e.g., microwave antenna tower; FM, AM, or TV antenna tower; suspension bridge; four-stack power plant; etc.).

2. **Latitude, Longitude, and Height.** Specify the latitude, longitude, and height(s) of each structure. When an obstruction evaluation study concerns an array of antennas or other multiple-type structures, specific information on each structure should be included.

3. **Marking and/or Lighting.** A marking and/or lighting recommendation shall be a condition of the determination when aeronautical study discloses that the marking and/or lighting are necessary for aviation safety.

**2.20.3 STATE PERMITS**

**2.20.3.1 State Environmental Policy Act**

*EFSEC*

*Ch. 463.47 WAC*

Compliance with SEPA is required before any state or local permits or approvals can be issued for the construction or operation of the facility. Skamania County would be the SEPA lead agency for local compliance absent EFSEC review at the State level. EFSEC is lead agency according to Chapter 463-47 WAC. The SEPA process is generally the same, regardless of lead agency.

**Compliance Plan**

On April 6, 2009 EFSEC will issue a Determination of Significance, a threshold determination requiring the preparation of a SEPA EIS, likely a Determination of Significance. This
will be followed by the preparation and issuance of a Draft EIS. The Final EIS will be published following the close of adjudicatory hearings.

It is anticipated that EFSEC will join BPA in the preparation of a joint NEPA-SEPA EIS that will suffice for both Federal and State permitting decisions. It is further anticipated that EFSEC and BPA will coordinate this effort with Skamania County to ensure that the County has ample opportunity to participate in the process, potentially as a cooperating agency.

2.20.3.2 Temporary Air Permit (for Concrete Batch Plant and for Rock Crushing)

*Southwest Clean Air Agency (SWCAA)*

*Ch. 70.94 RCW; Chs. 173-400; 173-460 WAC*

Ecology has regulations governing the operation of portable rock crushers and concrete batch plants. Both may be utilized during the construction of roadways and wind turbine foundations.

**Compliance Plan**

A temporary air permit would have been required for rock crushing for roadbeds and for one or more portable concrete batch plants (for mixing material for foundations) absent EFSEC jurisdiction. Whistling Ridge Energy LLC will comply with all substantive requirements of such permits. It is anticipated based on past practice that EFSEC would coordinate with the Southwest Clean Air Agency and Ecology as appropriate to ensure compliance with local, state and federal air pollution standards and regulations for the construction phase.

2.20.3.3 Forest Practices Application

*Washington State Department of Natural Resources (WDNR)*

*Ch. 76.09 and 76.13 RCW; Ch 222 WACA*

Forest Practices Application/Notification (FPA/N) would be required for activities on forest lands including timber harvest, construction of forest roads, installation or replacement of culverts or bridges on forest roads, and constructing or expanding gravel pits on forest land for forestry use absent EFSEC jurisdiction. Chapter 222-20-050 WAC and RCW 76.09.060(3) regulates portions of forest lands that are permanently removed from forestry use within three years of harvest, the forest practice as a Class IV General conversion. Reforestation of permanently converted areas is not required. The harvest must comply with applicable water typing, riparian management zone, and channel migration zone standards limiting the amount and location of timber removed in or near streams. A WDNR-approved Road Maintenance and Abandonment Plan would be required to inventory all existing and constructed forest roads, and to schedule any needed road work. All boundaries would be marked in the field prior to submittal of the FPA/N to WDNR.

**Compliance Plan**

The Whistling Ridge Energy LLC will comply with the substantive requirement and it is anticipated that EFSEC will coordinate with WDNR.
EFSEC will issue a SEPA determination specifying areas to be temporarily and permanently converted to non-forestry use because of the wind energy facility, and areas that are to remain in commercial forest production.

2.20.3.4 Construction Stormwater General Permit

Washington Department of Ecology
Federal Clean Water Act; 40 CFR Parts 122, 123 & 124, Subchapter D; Chs. 80.50 & 90.48 RCW; Chs. 173-216 & 220 WAC

Coverage under the 2005 Construction Stormwater General Permit will be required for stormwater discharges resulting from construction of the Whistling Ridge Energy Project. Construction activities that disturb more than five acres of land and certain industrial activities typically must file a notice of intent with Ecology and comply with the conditions of the general permits. Permit conditions include the preparation of SWPPPs to implement BMPs to prevent or control stormwater pollution, monitoring of discharges during construction, and regular reporting to Ecology.

Compliance Plan

EFSEC has jurisdiction regarding the NPDES Permit over the project, pursuant to WAC Chapter 463-38. Construction of the facility would disturb more than five acres of land, and EFSEC may require that the Whistling Ridge Energy Project obtain coverage under Ecology’s Stormwater General Permit for construction activities.

If coverage is deemed necessary by EFSEC, at least 30 days prior to beginning construction, Whistling Ridge Energy LLC would develop and submit to EFSEC a notice of intent to be covered by Ecology’s 2005 Construction Stormwater General Permit for discharges associated with construction. Pursuant to the general permit, Whistling Ridge Energy LLC would prepare SWPPPs that identify appropriate BMPs to reduce the pollution loadings resulting from construction activities and industrial operations. These BMPs would be incorporated into project design, and Whistling Ridge Energy LLC would ensure that they are observed during construction of the project. Monitoring and reporting would be carried out in accordance with permit requirements.

2.20.3.5 Approval for Over-Height and Over-Length Loads on State Highways

Department of Transportation
Road and Bridge Restrictions
Goldendale Office 509-773-4533

WSDOT has restrictions in place for portions of state highways that may be used for the transport of wind turbine equipment to the site. These load restrictions include limits on width, height, length, and weight, and vary depending on the specific roadway.

Compliance Plan

Whistling Ridge Energy LLC will work with WSDOT to select the preferred route for the transport of equipment from either the Port of Longview or the Port of Vancouver to the site. Options include
trucking, rail, and/or use of barges on the Columbia River. Depending on the option selected, the Applicant would comply with the requirements imposed by EFSEC and WSDOT.

2.20.3.6 Right of Way

Department of Transportation
Road and Bridge Restrictions
Goldendale Office 509-773-4533

There may be a need to improve and widen the turning radius of the intersection of SR 14 and Cook-Underwood Road for the deliver of turbines. Widening may require use of WSDOT right of way.

Compliance Plan

The Applicant will work with the WSDOT Goldendale Office to determine optimal intersection design and obtain right of way approval if necessary.

2.20.3.7 Water Well

Department of Ecology
Federal Safe Drinking Water Act; 42 USC § 300(f) Parts B & C
Ch. 18.104, 70.119A, and 90.44 RCW; Ch 173-160 and 246-291 WAC

Absent EFSEC jurisdiction, these matters would have been enforced by Ecology and Skamania County. Groundwater withdrawal wells for industrial use, including irrigation, of up to a maximum of 5,000 gallons per day are exempt from Ecology’s water right permit requirements. However, these permit-exempt wells must still comply with the minimum construction standards set forth in Chapter 18.104 RCW and the “first in time, first in right” clause of Washington State Water Law. The well/property owner and the well driller share responsibility for ensuring compliance with the standards. A Notification of Intent to Construct a Water Well form would be submitted to Ecology at least 72 hours prior to well construction. The well driller must file a copy of a Water Well Report with Ecology upon completion of well construction and must attach a well identification tag to the well. Wells must be located at least 100 feet from septic tanks, privies, and other sources of contamination as specified in Chapter 173-160-171 WAC.

Wells to be used for potable water must receive an approved Water Availability Verification Evaluation (WAVE) from Skamania County Community Development Department in accordance with SCC 8.68 and SCC Title 15. Permit-exempt wells not meeting the elimination conditions in Chapter 246-291 WAC are classified as Group B Public Water Systems and subject to standards in SCC 8.68 as administered by Skamania Community Development.

Compliance Plan

Whistling Ridge Energy LLC will comply with the substantive requirements. It is anticipated based on past practice that EFSEC would coordinate with Ecology and Skamania County.
2.20.3.8 Archeological Sites

Washington State Office of Archaeology and Historic Preservation

The Washington State Office of Archaeology and Historic Protection regulates and protects the cultural and historic resources on private and public lands in the State of Washington. The applicable statute is: Archaeological Sites and Resources, Chapter 27.53 RCW.

Compliance Plan

The project will comply with Chapter 27.53 RCW. The Applicant has researched state and federal registries along with all archaeological and historical files and maps located at the Washington State Office of Archaeology and Historic Preservation in Olympia.

2.20.3.9 Electrical Construction Permit

Department of Labor and Industries
Ch. 296-46 WAC

The Department of Labor and Industries is responsible for inspection of electric wires and equipment within the Whistling Ridge Energy Project, and requires that electric wires and equipment comply with National Energy Code standards.

Compliance Plan

Whistling Ridge Energy LLC will design and construct the project in compliance with the applicable electrical regulations and standards to ensure that the project complies with Department of Labor and Industries inspection requirements. Whistling Ridge Energy LLC will coordinate with EFSEC to ensure all necessary Department of Labor and Industries inspections and approvals are obtained.

2.20.4 SKAMANIA COUNTY

2.20.4.1 Skamania County Building Permit

Skamania County Building Official
Title 15 SCC

Absent EFSEC jurisdiction, a building permit is required for construction of the turbine foundations and permanent buildings, including the Operations and Maintenance building, and placement of identifying signs.

Compliance Plan

Whistling Ridge Energy LLC will comply with the substantive requirements for the building permit. It is anticipated based on past practice that EFSEC would coordinate with Skamania County.
2.20.4.2 Zoning

Skamania County Community Development Department
Title 21 SCC

SCC Title 21 governs all unincorporated areas of Skamania County except those portions located within the General and Special Management Areas of the Columbia River Gorge National Scenic Area. The proposed project lies within three zones designated in the existing SCC Title 21 (Figure 4.2-1, Zoning Map). No portion of the project or roads requiring improvements are located within the Scenic Area (Figure 2.1-1). However, some of the proposed improvements to existing roads are proposed in the General Management Area (GMA) of the Scenic Area (see Figure 2.1-1). Scenic Area compliance for the road improvements is discussed in Section 4.2 of this Application.

Turbine corridor A1-A7 falls into two zoning classifications. The south portion of the corridor, which could include up to a maximum of four turbines, is proposed in the Residential 10 (R-10) zone under SCC Title 21. The north portion of corridor A1-A7 will be in the Resource Production Zone (For/Ag 20). A maximum of three turbines could be located in this zone. The remaining turbine corridors are proposed in the unmapped zone. The alternative site for the Operations and Maintenance facility would be on land zoned Residential 5. Table 2.20-2 identifies the existing comprehensive plan designation and the zoning for each proposed turbine corridor in the project.

<table>
<thead>
<tr>
<th>Turbine Corridor</th>
<th>2007 Comprehensive Plan Designation</th>
<th>Zone Designation</th>
</tr>
</thead>
<tbody>
<tr>
<td>A8-A13, B1-B21, C1-C8, D1-D3, E1-E2 and F1-F3</td>
<td>Conservancy</td>
<td>Unmapped (UNM)</td>
</tr>
<tr>
<td>North portion of A1-A7 (maximum 3 turbines)</td>
<td>Conservancy</td>
<td>Resource Production Zone (For/Ag-20)</td>
</tr>
<tr>
<td>South portion of A1-A7 (maximum of 4 turbines)</td>
<td>Conservancy</td>
<td>Residential 10 (R-10)</td>
</tr>
<tr>
<td>Alternative Operations and Maintenance Site Along West Pit Road</td>
<td>Rural II</td>
<td>Residential 5 (R-5)</td>
</tr>
</tbody>
</table>

Compliance Plan

Turbines located within the unmapped zone are permitted outright by the County, limited only by an inquiry concerning whether the use would constitute a “nuisance.” Turbines located within the Resource Production Zone and Residential Zone are allowed by Conditional Use approval. The alternative location for the Operations and Maintenance facility would be on land zoned Residential 5, and would also be allowed by Conditional Use approval. Standards in SCC 21.40.050 and 21.56.050 include limitations as to lot size, density, setbacks, a 35-foot building height limit, off-street parking requirements, and prohibition of building location within easements. As proposed, the project meets all these requirements.

While EFSEC’s jurisdiction and authority over local land use requirements and determinations is now well established, the analysis contained in Section 4.2.1 of this application demonstrates that, as
of the date of this application, the project can and does comply with the 2007 Comprehensive Plan, and both the zoning code in effect at the time of this Application (SCC Title 21). The Applicant anticipates this project will be fully consistent with the Skamania County Code and that it will meet local requirements.

### 2.20.4.3 Noise Regulations

*Skamania County Sheriff Department*

*Ch. 8.22 SCC; Ch. 70.107 RCW; Ch. 173-60 WAC*

Although no permit is required, absent EFSEC jurisdiction the Skamania County Sheriff Department would be responsible for noise control and abatement under SCC Title 8. SCC Title 8 relies on State standards established for maximum environmental noise levels. Permissible noise levels established by state and local regulation vary depending on the source of the noise (which in this case is “industrial”) and the nature of the receiving environment (in this case, largely industrial and agricultural with some residential). Noise performance standards established by state regulation must be met during the construction and operation of the project.

#### Compliance Plan

The project will be designed to ensure that all noise generated will be below the applicable standards with noise mitigation measures. Modeling indicates that the Whistling Ridge Energy Project will meet all applicable noise regulations which will be enforced by EFSEC. See Section 4.1.1, Noise.

### 2.20.4.4 Critical Areas Ordinance

*Skamania County Community Development Department*

*Ch. 21A SCC; Ch 36.70; 36.70A RCW*

The Skamania County Critical Areas Ordinance would apply absent EFSEC Jurisdiction. SCC 21A.03.010 states that “no building, structure or land shall be used, and no building, structure or road shall be hereafter erected, altered or enlarged, including those proposed by State or Federal agencies, in any designated critical area governed by this title, except as allowed by this title.” The Critical Areas Ordinance includes a number of exemptions that may be applicable. Proposed improvements to existing private roads will extend outside previously-disturbed areas within critical areas outside the Scenic Area, so that they do not meet any of the allowed exemptions. SCC Title 21A would apply to the project. Two application types are established under SCC 21A.03.030:

1. Variances to buffers established under SCC 21A.04 governing watershed protection areas

2. Development reviews under SCC 21A.05 (Fish and Wildlife Protection Areas) and SCC 21A.06 (Geologically Hazardous Areas)

#### Compliance Plan

Title 21A does not apply in the Scenic Area. West Pit Road crosses one unnamed drainage in the Lapham Creek watershed. This stream had observed flow through the existing culvert under West
However, the surface flow and the channel disappear downstream of the culvert. West Pit Road and the underlying culvert would be widened to allow access to the site by construction vehicles. No new construction will occur within streams or their buffers outside the Scenic Area. The planned road improvements that will occur within stream buffers will result in expansion of existing roads to an extent that is less than 100% of the original footprint. Thus, no variance would be required under SCC Title 21A.03.030(1) to complete the project according to SCC SCC 21A.020(B)(2)(g and i).

Critical area mitigation requirements, if necessary, are site-related, and may be implemented by EFSEC. EFSEC requirements related to critical areas would be similar to the substantive requirements resulting from the implementation of SCC Title 21A.03.030(2). Watershed protection areas (streams and wetlands) are addressed in Sections 3.3 Water, 3.4 Habitat, Vegetation, Fish and Wildlife, and 3.5 Wetlands. Fish and Wildlife Protection Areas are addressed in Section 3.3, Water. Geologically Hazardous Areas are addressed in Section 3.1, Earth.

### 2.20.4.5 Clearing and Grading Permit

*Skamania County Community Development Department*

*Ch. 24 SCC; Ch 36.70; 36.70A RCW*

Absent EFSEC jurisdiction, a Skamania County Clearing and Grading Permit would be required. A new Chapter of SCC, Title 24 Clearing and Grading, was adopted by the Skamania Board of County Commissioners in February 2008. All grading activity not exempted under SCC 24.02.060 would be prohibited without first obtaining a Clearing and Grading Permit under SCC Title 24.

**Compliance Plan**

Detailed clearing and grading plans prepared by an Engineer licensed in the State of Washington will be prepared and submitted to EFSEC for review and approval prior to the start of construction. These plans will substantively comply with SCC Title 24 standards.

### 2.20.4.6 Water Availability Verification Evaluation and Group B Public Water System Approval

*Skamania County Community Development Department*

*Ch. 8.68 and 15 SCC; Ch 50.56 and 70.119A; Ch 246-291 WAC*

Absent EFSEC jurisdiction, a Group B Public Water System Approval would be required for permit-exempt industrial water wells that may be used as a drinking water source. The Operations and Maintenance facility proposed in conjunction with the project would be used as such a source.

To document proof of potable water, a WAVE approval would be required from Skamania Community Development.

**Compliance Plan**

The project will comply with applicable potable water and Group B Water System Standards. Based on past practice, it is anticipated that EFSEC will coordinate with Skamania County and Ecology.
2.20.4.7 On-Site Septic System Site Evaluation and Design Review

_Skamania County Community Development Department_
_Ch. 70.118 RCW; Ch. 246-272A WAC; Federal Safe Drinking Water Act 42 USC § 300(f) Parts B & C_

Absent EFSEC jurisdiction, Skamania Community Development would be responsible for ensuring site and design standards identified in WAC 246-272A are met. Generally, a Site Evaluation is requested to determine the type of system required prior to installation of a new on-site septic system. A Site Evaluation Results Letter is issued, which is valid for one year. The project proponent must then hire a qualified on-site septic system designer to design a system for the site in accordance with the Site Evaluation Results Letter. The design must then be submitted for Design Review. An approved Design Review is valid for five years from the date of issuance. Extensions may be granted under certain circumstances.

Compliance Plan

The project site will be evaluated as to applicable on-site septic system design standards and all systems will comply with these standards. It is anticipated that EFSEC will coordinate with Skamania County.

2.20.4.8 Road Approach Permit and Private Road Requirements

_Skamania County Public Works Department_
_Ch. 12.03 SCC; Skamania County Road Approach and Private Roads Standards Development Assistance Manual_

The proposed road improvements to West Pit Road required to access and construct the project include modifications to existing logging roads and new construction outside the Scenic Area. Improvements to an unnamed private road within the Scenic Area also are proposed. County Assessor’s maps identify the existing road in the Scenic Area as CG2930 (County Assessor maps 3-10, 3-10-19, 3-10-20). Figure 4-1 of the 2007 Skamania County Comprehensive Plan does not include the CG2930 road as part of the system of County roads. West Pit Road is an existing private logging road. All private roads in Skamania County must comply with guidelines in the Private Road Guidelines and Development Assistance Manual adopted by County Resolution in 2008 (SCC Title 12.03.030) “where a proposed change in use converts a private driveway (Category 1 road) to a higher category road (SCC 21.03.070).” Also, a road approach permit is required where a private road enters a County road.

SCC 12.03 classifies private roads by use (12.03.030). Current use of the CG2930 West Pit Road road is for access to ongoing forest operations taking place in and outside the Scenic Area. No homes are accessed via this road. Because it accesses fewer than four homes, the CG2930 road West Pit Road is a Category 1 road under SCC 21.03.030. Existing logging roads outside the Scenic Area are also currently Category 1 roads.

The Applicant’s proposed wind energy facility would establish a new use on property outside the Scenic Area. It is not likely this change in use will convert the existing Category 1 roads to
Category 6 roads (SCC 21.03.030). However, construction of the project would have impacts to existing County roads and to existing Category 1 private roads that would require road upgrades and repair before, during and after construction. The specifics of this work would be determined through negotiation of a Haul Route Agreement with the County Engineer, which will be approved by the Board of County Commissioners.

A Road Approach Permit may be required where the CG2930 road new connection of West Pit Road enters Scoggins–Willard Road. The specific requirements of this permit would be negotiated with the County Engineer and would likely exceed Category 6 (commercial) private road approach requirements due to the nature of the project. However, it is also likely the project’s access road would not be required to meet Category 6 standards for its full length as traffic volumes will remain very low.

Compliance Plan

Whistling Ridge Energy LLC will comply with Skamania County Private Road Requirements as administered through EFSEC. A Haul Route agreement and Road Approach permit will be negotiated to protect and repair Skamania County roads.

2.20.4.9 Columbia Gorge National Scenic Area Permit

Skamania County Community Development Department
Chapter 22.14 SCC

The Applicant proposes minor upgrades to access roads located on private lands (owned and controlled by S.D.S. Co., LLC), situated within the Columbia River Gorge National Scenic Area. No portion of the wind turbine generator corridors or any related facilities are proposed within the Scenic Area, and the Scenic Area does not regulate any development activity proposed outside the Scenic Area boundary.

Columbia River Gorge National Scenic Area Permit Requirements

The Columbia River Gorge National Scenic Area Act places restrictions on development within the Scenic Area. The boundaries of the Scenic Area are defined in the Act by reference to a “map entitled ‘Boundary Map, Columbia River Gorge National Scenic Area,’ numbered NSA-001 sheets 1 and 2, and dated September 1986,” which is on file with the Commission. Additionally, S.D.S. Co., LLC had the Scenic Area boundary surveyed by Terra Surveying, a licensed land surveyor, in 2006 and 2007. This survey was reviewed for accuracy by USFS Surveyor Don Karsch, who is responsible for reviewing such surveys to establish the Scenic Area boundaries. The survey was accepted by the USFS and recorded in Skamania County with an Auditor’s File Number of 2007167932. Certain uses are allowed without review, but some uses require prior approval and others are prohibited. The restrictions depend, in part, on whether the proposed use will take place in the General Management Area (GMA) or a Special Management Area (SMA). The boundaries of the SMAs are defined in the Act by reference to a “map entitled ‘Special Management Areas, Columbia River Gorge National Scenic Area,’ numbered SMA-002 sheets 1 through 17, and dated September 1986,” which is on file with the Commission.
The proposed access to the site would be via an existing private logging road, listed as CG2930, connecting to Scoggins Road, which is a County road. CG2930 is currently narrow, approximately 10 to 12 feet wide, and will require permanent widening to a minimum drivable section width of 16 feet with allowance for side slope and drainage from Scoggins Road to the proposed project site (see Figures 4.3-17 through 4.3-25 in Section 4.3). Widening would require possible removal of trees, and possible engineered fill and embankment cut sections. The engineered fill and embankment cut sections would not require paving, but would require an all-weather driving surface. There are two sharp left hand turns in the roadway enroute to the proposed project site (Figures 4.3-17, 4.3-23, and 4.3-24) that will require additional special considerations to accommodate the required truck turning radii for transport of the wind energy blades to the site. Road CG2930 is located within the CRGNSA and approval would be required under applicable standards in conjunction with SEPA and building permit approvals before making roadway improvements.

Certain uses are allowed without review in both the GMA and SMAs, including repair, maintenance and operation of roads. A person can also resurface or overlay existing paved roads and grade and gravel existing road shoulders, provided that the activity does not: (i) increase the width of the road; (ii) disturb the toe of adjacent embankments, slopes or cut banks; or (iii) change the existing structures or add new structures. Forest practices, including the construction of roads, are also allowed in the GMA as long as the practices do not violate conditions of approval for other approved uses and developments. However, a forest practice must relate to growing, harvesting, or processing timber.

The road improvements proposed within the Scenic Area do not fall within any of these exemption categories. The Applicant needs to improve, rather than repair, maintain, or operate, the road. Further, the necessary improvements include widening the existing road. While “forest practices” is a broad category that includes road construction, the improvement of roads for wind energy facility construction does not fall within the definition because wind energy facilities do not relate specifically to growing, harvesting, or processing timber.

The Applicant’s road improvements fall within the category of uses that “may be allowed subject to review by the County Administrator for compliance with all applicable provisions protecting scenic, cultural, natural and recreation resources.” In SMAs, the use must also be sited to minimize the loss of land suitable for the production of forest products. Uses the Administrator may allow subject to review on GMA lands designated as large-scale agriculture, commercial forest, large woodlands, or small woodlands include construction, reconstruction or modification of roads, not in conjunction with forest use or forest practices. Uses the Administrator may allow subject to review on SMA lands designated as forest include road and railroad construction and reconstruction. Therefore, but for EFSEC consideration of the ASC, the improvements would subject to an administrative review and approval, regardless of whether the road is located in the GMA or SMAs.

Compliance Plan

The Applicant proposes minor upgrades to access roads located on private lands (owned and controlled by S.D.S. Co., LLC) and County rights of way, all of which are situated within the Scenic Area GMA. No portion of the wind turbine generator corridors or any related facilities are proposed within the Scenic Area, and the Scenic Area does not regulate any development activity proposed outside the Scenic Area boundary. In a non EFSEC application, applicable approvals for road
improvement work within the Scenic Area would be administered through Skamania Community Development, with appeal to the Columbia River Gorge Commission, and ultimately resolved through the State of Washington judicial appeals system. Pursuant to RCW Ch. 80.50, in this Application, the EFSEC process preempts the local process for approval of the road improvements within the Scenic Area. However, the Applicant plans to comply with all requirements set forth below by satisfying the EFSEC that all Scenic Area requirements can be met through the EFSEC application process.

Whistling Ridge Energy LLC has included information within this Application that demonstrates project compliance with the requirements of the Scenic Area for the proposed roadway improvements. See Sections 3.1 Earth, 3.3 Water, 3.4 Habitat, Vegetation, Fish and Wildlife, 3.5 Wetlands, 4.2 Land and Shoreline Use, and 4.3 Transportation.
SECTION 3.1 EARTH  
(WAC 463-60-302)

3.1.1 INTRODUCTION

The proposed Whistling Ridge Energy Project would be located approximately 7 miles west of the town of White Salmon and approximately 2 miles east of the Little White Salmon River in Skamania County, Washington. The project area is located on private land immediately north of the Columbia River Gorge National Scenic Area boundary. Existing conditions, potential impacts, and, where appropriate, mitigation measures are discussed below. The following sections include detailed evaluation of geology, soils, topography, unique physical features, and erosion/enlargement of the land area.

URS conducted a preliminary geotechnical investigation in 2007, including review of aerial photographs, geologic reconnaissance, test pit analyses, field soil resistivity testing, dynamic cone penetration tests, laboratory testing of soil samples, data analyses, and preparation of design and construction recommendations for the wind energy tower foundation systems and design of approach roadways. See Appendix A for an updated version of the November 2007 geotechnical report.

Site-specific measures have been identified to mitigate potential hazards. With standard and site-specific mitigation measures, impacts on the natural earth environment from the construction and operation of the Whistling Ridge Energy Project are expected to be minor.

3.1.2 GEOLOGY

The White Salmon, Washington area is located within the Cascade Range and the Columbia Intermontane Physiographic Province. The project area is located just within the western boundary of the Columbia Plateau, which is located at the western edge of the Columbia Intermontane Physiographic Province (Freeman et al. 1945). This lowland province is surrounded on all sides by mountain ranges and highlands, and covers a vast area of eastern Washington and parts of northeastern Oregon and western Idaho. The Columbia Plateau is underlain by a series of layered basalt flows extruded from vents (located mainly in southeastern Washington and northeastern Oregon) during the Miocene epoch (between 5.3 and 23.8 million years BP). Collectively, these basalt flows are known as the CRBG. Individual basalt flows range in thickness from a few millimeters to as much as 300 feet. Where significant time elapsed between successive flows, interflow zones developed. The interflow zones are characterized by the presence of highly weathered basalt and paleosols. These interflow zones are generally significantly weaker than the surrounding basalt and sometimes form basal failure surfaces for large landslide complexes within the CRBG.

A variety of younger volcanic rocks and sedimentary materials that range from Pliocene (1.8 to 5.3 million years BP) to Holocene (less than 10,000 years BP in age) overlie the CRBG in the project area. Sedimentary rocks are generally thought to underlie the basalts in the project area.
The proposed project site is located within the northern boundary of the structural Hood River Valley, which extends a few miles into southern Washington. In general, the geology of the area consists of basalt flows extruded from local vents, layered with conglomerate, tuff, tuff breccias, and other volcanoclastic deposits. These formations are typically overlain by silt and clay soil of varying thickness in the project vicinity.

The bedrock underlying the proposed project site consists of Grande Ronde Basalt of the CRBG and Quaternary basalt of Underwood Mountain—a shield volcano that lies approximately midway between the lower reaches of the Little White Salmon and White Salmon Rivers. Its southern slopes drain to the Columbia River. Site geology excerpted from Korosec (1987) is presented on Figure 3.1-1.

**Underwood Mountain Basalt Unit:** The Pleistocene-epoch (1.8 million years to 10,000 years BP) basalts and cinders erupted from the Underwood Mountain vents and overlie the Tertiary CRBG Grande Ronde and Wanapum basalts. Public records of wells located within the Underwood volcanic field indicate a 310-foot-thick repetitive sequence of thin lava flows (two to eight feet thick), cinders and silty-clays overlying a productive confined aquifer consisting of intensely fractured Grande Ronde basalt. The Miocene-epoch Grand Ronde Basalt consists of multiple basalt flows that are a subgroup of the CRBG, and has been described to have a thickness of up to 1,000 feet, although the thickness in the project vicinity is not known.

Field observations of rock outcrop and test pits excavated during a geotechnical investigation at the proposed site indicate that the near-surface rock consists of yellow-gray volcanoclastic rocks, medium to dark gray, fine-grained to medium-grained basalt and andesite, which is fractured into angular gravels, cobbles, and boulders. The basalt observed in the test pits was most commonly vesicular, very soft to moderately hard, and decomposed to slightly weathered. Some zones displayed non-vesicular characteristics and were generally harder. In most exposures the basalt was moderately to highly weathered, with fractures and vesicles filled by clayey residual soil. In most of the test pits excavated in this basalt, the rock is weathered into varying layers of residual (clay) soil, and clayey gravelly cobble-sized basalt. The residual soil layers often exhibit remnant rock structure.

**Unconsolidated Deposits:** Unconsolidated deposits are thin to absent in the project vicinity. Based on observations made during field reconnaissance, the surficial materials consisted primarily of a thin veneer of brown, silty topsoil that is likely derived from forest duff and wind-blown deposits. The thickness of this material varied across the site from a few inches to three feet, based on test pit observations. In several areas, bedrock and talus were observed at the ground surface.
Revised Figure 3.1-1

Site Geology

Whistling Ridge Energy Project
Skamania County, Washington
**Landslide Deposits:** Regional geologic maps indicate the presence of Quaternary-age mass wasting landslide deposits located to the north of Underwood Mountain (Figure 3.1-1). These deposits are mapped as a large landslide, estimated to be approximately 1/3 square mile in area and almost a mile long. A URS engineering geologist reviewed stereo aerial photographs that were flown specifically for this project in 2007 and performed a one-day site reconnaissance. There is no obvious evidence, based on the review, to suggest the presence of a landslide as mapped on the 1:100,000 scale geologic map. If landslide deposits are present, they are so old that most or all of the geomorphic evidence has been removed by erosion.

During the current subsurface exploration, groundwater was not encountered in the site up to a depth of 16 feet bgs. It should be noted that these observations reflect groundwater levels at the time of the field investigation and actual groundwater levels may fluctuate significantly in response to seasonal effects, regional rainfall, and other factors not observed during this investigation. There may be regional or perched water tables at greater depth. Prior to final design of the tower foundations, additional subsurface investigations (boreholes) would be required to provide geotechnical data at foundation and anchor depths. Future deep foundation investigations would include observation of groundwater, if encountered.

### 3.1.3 SEISMICITY

Strong ground motions potentially affecting the site can be generated from earthquakes on several regional seismic sources. Earthquakes are the result of sudden releases of built-up stress within the tectonic plates that make up the earth’s surface. The stresses accumulate because of friction between the plates as they attempt to move past one another. Earthquakes in the Pacific Northwest can originate from four different types of sources: (1) interplate earthquakes on the CSZ, (2) intraplate earthquakes within the subducting Juan de Fuca plate as it sinks and breaks up below the North American plate, (3) shallow crustal earthquakes on faults within the North American plate, and (4) volcanic earthquakes such as those associated with the eruption of Mount St. Helens. These sources are depicted on Figures 3.1-2 and 3.1-3. The largest historical earthquakes in Washington, southern British Columbia, and northern Oregon are shown on Figure 3.1-4 and summarized in Table 3.1-1.

</table>
The historic record of seismicity in the Pacific Northwest (approximately 150 years) is insufficient to provide documentation of great earthquakes (i.e., $M_w$ 8 or greater) on the CSZ. There has been a low rate of instrumental seismicity recorded and the CSZ was originally thought to be incapable of generating great earthquakes. In the late 1980s, Rogers (1988) and Heaton and Hartzell (1986) inferred that an $M_w$ 9 CSZ earthquake could occur that would rupture the entire 900-kilometer length of the Juan de Fuca plate between the Explorer plate (offshore Vancouver Island, BC) and Gorda plate (offshore northeastern California). Geodetic data indicate that western Washington and southwest British Columbia are moving to the northeast with respect to stable North America and the rates of movement diminish landward (McCaffrey et al. 2007). Geologic studies along the Oregon and Washington coasts in the late 1980s through mid-1990s provided data that indicated that multiple great ($M_w$ 8+) earthquakes have occurred on the CSZ during the Holocene (Atwater 1987a, 1987b, and 1992; Carver and Burke 1987; Darienzo and Peterson 1987 and 1990; Grant and McLaren 1987; Peterson and Darienzo 1996; Savage et al. 1991; Adams 1996; Atwater et al. 1995; Nelson and Personious 1996; Shennan et al. 1996) and therefore could occur during the project lifetime. However, it was uncertain whether a single $M_w$ 9+ earthquake or several separate $M_w$ 8+ earthquakes closely spaced in time caused the geologic effects (e.g. subsidence, tsunami deposits, and drowned forests) with similar ages recorded at the various study locations along the Washington and Oregon coasts.

By the mid-1990s there was a general consensus that the CSZ has generated earthquakes of $M_w$ 8+ in the past few thousand years (Atwater et al. 1995, Nelson and Personious 1996, and Weaver and Shedlock 1996), and since then there is increasing evidence that the CSZ has had multiple $M_w$ 8+ and 9+ earthquakes in the last five thousand years (Kelsey et al. 2002 and 2005, Witter et al. 2003, Nelson et al. 1995). Geologic evidence for the most recent great earthquake in 1700 AD has been found at many coastal locations in Washington and Oregon, as well as northern California (Nelson et al. 1995, Yamaguchi et al. 1997). Analysis of historical records of tsunamis in Japan supports the interpretation that a 1700 AD great earthquake on the CSZ was about $M_w$ 9 (Satake and Tanioka 1996, Satake et al. 2003, Atwater et al. 2005).

A single great earthquake of $M_w$ 9+ or multiple $M_w$ 8+ earthquakes occur on the CSZ every several hundred years. At least 10 great earthquakes have occurred in Washington and northern
Oregon in the last 5,000 years with recurrence intervals between the earthquakes ranging from 250 to 900 years. Eight of these 10 events ruptured at least 460 km of the CSZ along the Washington and northern Oregon coasts and the earthquake approximately 1,600 years BP was of similar size and rupture length as the 1700 AD earthquake (Nelson et al. 1995). These earthquakes are expected to occur at depths of approximately 6 to 25 miles beneath coastal and offshore Washington and/or Oregon. An Mw 8+ earthquake on the CSZ offshore southwest Washington and northwest Oregon would generate long period ground motions for a relatively long duration at the Whistling Ridge Energy Project site.

Intraplate seismic events appear to be more widespread geographically and result from rupture within the subducted Juan de Fuca plate at depths of 20 to 55 miles. Based primarily on the historical seismicity of intraplate origin in western Washington and other subduction zones of the world, the intraplate zone is considered capable of generating earthquakes as large as Mw 7.5. Because intraplate earthquakes do not cause deformation at the ground surface that can be distinguished from other types of earthquakes, the typical frequency of these earthquakes cannot be readily assessed. However, these types of earthquakes have historically caused the greatest amount of damage in the Puget Sound region. This source has generated three of the largest historical seismic events to affect the Pacific Northwest: the 1949 Olympia earthquake of magnitude (M) 7.1, the 1965 Mw 6.5 Seattle earthquake, and the 2001 Nisqually Mw 6.8 earthquake. These earthquakes caused substantial damage in central and southern Puget Sound but no substantive damage in the White Salmon area. There have not been any historical, damaging intraplate earthquakes with epicenters located in Oregon or southern Washington in the northern portion of the Willamette Lowland.

There is increasing geologic and geodetic evidence that other regional seismic sources in western Washington and Oregon have the potential to produce shallow continental crust earthquakes. Shallow crustal seismic events appear to be more widespread geographically relative to the other sources of historical seismicity, and often occur along mapped or postulated faults exposed at the earth’s surface. A regional geologic fault slip model indicates that the predicted long term velocity of the Oregon Coast Ranges relative to stable North America in southern British Columbia is $1.8 \pm 0.4$ millimeters per year (mm/yr) east and $6.9 \pm 0.2$ mm/yr north measured at Astoria, Oregon. This is consistent with the geodetic data, which indicate a net velocity of $7.1 \pm 0.4$ mm/yr. Of this motion, $4.4 \pm 0.3$ mm/yr is likely accommodated by north-northeast shortening across western Washington and the Puget Sound region between Astoria and Bellingham, Washington (McCaffrey et al. 2007). Based primarily on historic and paleo-seismicity, Quaternary shallow crustal faults are considered capable of generating earthquakes greater than Mw 6 and potentially as large as Mw 7.0 to Mw 7.5. The largest historical shallow crustal earthquake is the 1872 North Cascade event, which was initially estimated to be M 7.3 (Noson et al. 1988), but more recently has been relocated to near Lake Chelan and is estimated to have been between Mw 6.5 and Mw 7.0 at the 95% confidence interval (Bakun et al. 2002). The largest instrumentally recorded shallow crustal earthquake in the Portland Basin area is the 1962 M 5.5 earthquake, located 15 km northeast of downtown Portland (Wong and Bott 1995). This has not been definitively associated with a recognized late Quaternary fault.

Studies by Pezzopane (1993), Geomatrix Consultants (1995), and Wong et al. (1999), among others, and more recent compilations by the USGS (Lidke et al. 2003 and Personius et al. 2003)
show numerous shallow crustal faults with evidence of Quaternary displacement and a potential to generate an \( M_w \) 6+ earthquake exist in southwestern Washington and northwestern Oregon (Figure 3.1-3). A decade ago, many of these faults were unknown or not recognized as being seismogenic.

No faults are mapped within the footprint of the proposed project area. However, faults are mapped approximately 1.5 miles southwest and northeast of the proposed project area. Many of these faults are inferred and shown as dotted lines assumed to be buried by younger surficial deposits. The activity of the area faults is unknown. However, a review of aerial photography shows no indication of recent movement along the trace of the inferred faults.

There has not been an historical surface-rupture earthquake on any fault within northwestern Oregon or southwestern Washington, and paleoseismic investigations of the regional faults have been limited to date. The closest Quaternary faults to the site are the Hood River fault south of the site in Northern Hood River County, Oregon (No. 29 in Figure 3.1-5), the faults near the Dalles east and west of the site (No. 48 in Figure 3.1-5), and the Columbia Hills fault zone on the north shore of the Columbia River southeast of the site (No. 45 in Figure 3.1-5).

According to the updated National Seismic Hazard Maps published by the USGS in 2008 (Peterson et al. 2008 and http://earthquake.usgs.gov/research/hazmaps/), the peak ground acceleration estimated for the Whistling Ridge Energy Project site area is 0.128\( \text{g} \) for a 475-year return period earthquake (i.e., ground motion with a 10 percent chance of being exceeded in 50 years) and 0.244\( \text{g} \) for a 2,475-year return period earthquake (i.e., ground motion with a 2 percent of being exceeded in 50 years).

### 3.1.3.1 Impacts

Liquefaction is a phenomenon whereby soils undergo significant loss of strength and stiffness when they are subjected to vibration or large cyclic ground motions produced by earthquakes. Typically, cyclic loading of saturated soils leads to the buildup of excess pore-water pressure as a result of soil particles being rearranged with a tendency toward denser packing. Under undrained conditions (such as during earthquake shaking), loads are transferred from the soil skeleton to the pore-water with consequent reduction in the soils’ shear strength.

Saturated granular soils without cohesive fines (i.e., gravels, sands, and silts) are most susceptible to liquefaction. Other factors affecting the potential for liquefaction in soils are density, amplitude of loading, confining pressure, past stress history, age of soil deposit, the size, shape and gradation of particles, and the soil fabric structure. Liquefaction-induced ground settlement and lateral spreading have been the primary cause for extensive damage to aboveground structures, foundations, and pipelines during many earthquakes.

Test pits excavated at the project site encountered shallow bedrock covered with a combination of cohesive and cohesionless soil. No groundwater was observed in any of the test pits. Based on the soils encountered during the field explorations, it is URS’s opinion that the potential for liquefaction is very low at this site.
Figure 3.1-5

Quaternary Faults and Seismic Source Zones in Northwest Oregon and Southwest Washington

Job No. 33758687
The risk of seismically induced settlement and lateral spreading is low due to the low liquefaction potential. It is URS’s opinion settlements and lateral spread induced by a seismic event would be minimal.

Coseismic surface rupture occurs when a fault breaks to the land surface during an earthquake. Surface rupture is usually associated with moderate to large earthquakes (Mw 6.5 or greater) or rarely during smaller, very shallow events. There are no mapped faults crossing the site. Therefore, the potential for coseismic primary surface rupture at the proposed project site is small.

Seismic slope instability could potentially affect the site access road. However, the proposed access road does not cross any mapped landslides, nor were any observed during a preliminary site investigation.

3.1.3.2 Mitigation Measures

No mitigation measures are proposed beyond adhering to local building codes and standard turbine and foundation design. The proposed facility would comply with the state building code provisions for seismic hazards applicable to the proposed location. Access road designs would comply with applicable county, state, and federal codes.

3.1.4 SOILS

3.1.4.1 Existing Environment

Whistling Ridge Energy Project Site

Soils in the project area are shown on Figure 3.1-6. The NRCS describes the soils in the project vicinity as follows (USDA 2003):

- **Chemawa Series:** The Chemawa series consists of very deep soils (up to five feet) formed in alluvium from volcanic ash and basalt. The soils exist on terraces, footslopes and backslopes at elevations between 800 and 2,500 feet in southeast Skamania County and southwest Klickitat County. Chemawa Soils are well drained with slow to medium runoff and moderate permeability. The Chemawa series soils are present in areas that would be crossed during access to the site, but are not present within the boundaries of the proposed wind turbine site.

- **McElroy Series:** The McElroy series consists of very deep soils (up to five feet) formed in colluvium and residuum from basalt with a mantle of volcanic ash that influences soils in the top nine to 13 inches. The soils exist on the footslopes and backslopes of mountains on slopes from five to 90 percent at elevations from 400 to 2,600 feet in eastern Skamania County and western Klickitat County. McElroy Soils are well drained with medium to rapid runoff and moderate permeability. The series was established in 1981 following the introduction of volcanic ash from the eruption of Mt. St. Helens.
Revised Figure 3.1-6

Soil Classifications

Whistling Ridge Energy Project
Skamania County, Washington

Source: GeoDataScape.
Job No. 33758687

URS
• **Timberhead Series:** The Timberhead series consists of very deep soils (up to five feet) formed in residuum and colluvium from basalt mixed with volcanic ash. The soils exist on mountain ridges between five and 30 percent at elevations from 2,000 to 3,600 feet in Skamania County and western Klickitat County. Timberhead Series soils are well drained with medium to rapid runoff and moderately high to high permeability.

• **Underwood Series:** The Underwood series consists of very deep soils (five feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between two and 50 percent at elevations between 500 and 2,700 feet in southeast Skamania County and west Klickitat County. Underwood Series soils are well drained with slow to medium runoff and moderately high permeability.

• **Undusk Series:** The Undusk series consists of very deep soils (five feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between five and 65 percent at elevations between 2,000 and 2,800 feet in southeast Skamania County and west Klickitat County. Undusk Series soils are well drained with slow to medium runoff and moderately high permeability.

Based on the current test pits and field observations, the site soil is best represented as **Stiff Soil/Soft Rock (IBC Soil Site Class D B)**. Rock, with varying strength and weathering characteristics, was encountered at shallow depths (ranging from three to 12 feet bgs).

Prior to final design of the tower foundations, additional subsurface investigations (boreholes) would be required to provide geotechnical data at foundation and anchor depths.

### 3.1.4.2 Impacts

**Whistling Ridge Energy Project Site**

Foundations for the wind turbines and the grading plan would be determined during final design.

Because surface soils on the project site are considered moderately susceptible to erosion, there is potential for adverse impacts on the site soil in areas of steep topography during grading and foundation construction activities.

**Roadway Improvements**

Improvements to existing roadways and construction of new access and maintenance roads are anticipated for construction and operations of the proposed facility. For the current proposed number of wind turbines, approximately 350 over-size and/or overweight loads would be required over the County and site roads for the towers only, in addition to construction equipment. This quantity does not include delivery of construction materials such as concrete required for the foundation, grading equipment to construct roads and prepare the site or other...
construction traffic not associated with the Whistling Ridge Energy Project. Improvements to the County roadways and the private logging roads would be necessary to support the long and heavy loads that would be required for the delivery of the wind energy components from SR 14 to the proposed project site are discussed in Section 4.3.2.2, Roadway Improvements.

URS drove and observed the haul roads on the property during our September 2007 and June 2009 site visits. The existing logging road (CG2930 West Pit Road) to the site has been used primarily for accessing stands of timber for harvesting and exporting timber from the site. At the time of the June 2009 site visit, the dirt road was surfaced with soil and rock, and is in poor condition, and is not suitable for the trucks that would be carrying the wind tower equipment. Roadway improvements were made during the summer 2009 to widen the road for logging purposes, however additional widening and surface improvements would be required for the wind project.

URS would analyze the existing topography and work within the equipment limitations of the haul trucks that would be transporting the equipment to the site. Likely this would include rebuilding large sections of the existing road and surfacing with rock. For areas with steep slopes, there may be a need to flatten and rebuild the slopes to allow access by the hauling equipment. In addition, a new connection would be made between West pit Road and Willard Road, and portions of the West Pit Road widened and realigned beyond the improvements made for logging access. These modifications would likely require construction of new cut and fill slopes.

3.1.4.3 Mitigation Measures

Site-specific geotechnical engineering evaluations would be conducted prior to design of the project to identify design methods to address the potential impacts presented above. Mitigation of soil impacts at the site would be incorporated into the final design of the foundations and roadways. A SWPPP would be developed prior to construction or modification of any roads or facilities. The SWPPP would be submitted for approval to EFSEC and followed throughout construction at the site.

3.1.5 TOPOGRAPHY

3.1.5.1 Existing Environment

**Whistling Ridge Energy Project Site**

The area of the proposed project is approximately 1,152 acres. The project site is located on a series of north trending ridges that range in elevation from approximately 2,100 to 2,300 feet above msl. The land west of the proposed project site drops sharply to a narrow river terrace and then to an elevation of less than 800 feet above msl in the Little White Salmon River valley. The topography northeast of the site drops gradually toward the White Salmon River or climbs gently up the northeast flank of Underwood Mountain at 2,728 feet above msl. To the south, the topography drops to a terrace of largely agricultural use and then toward the Columbia River. Site topography is shown on Figure 3.1-7.
3.1.5.2 Impacts

**Whistling Ridge Energy Project Site**

Impacts to the topography due to construction of the Whistling Ridge Energy Project would include grading of access roads and foundations. The areal footprint of the grading and total volume of material excavated would depend on the final foundation design(s) of the turbine towers.

**Roadway Improvements**

Roadway improvements would be necessary to accommodate the heavy and long loads associated with the turbine towers. It is anticipated that some steep sections of existing or new roads would be regraded to create shallower grades. Some tight-radius turns may require localized realignment of existing site roadways. These modifications would likely require construction of new cut and fill slopes.

3.1.5.3 Mitigation Measures

No mitigation measures for topography are anticipated at this time.
Figure 3.1-7

Site Topography

Job No. 33758687

Whistling Ridge Energy Project
Skamania County, Washington
3.1.6 UNIQUE PHYSICAL FEATURES

3.1.6.1 Existing Environment

URS conducted a preliminary landslide hazard evaluation of the proposed Whistling Ridge Energy Project wind turbine site pursuant to SCC Title 21A, Chapter 21A.06 - Landslide Hazard Areas.

A URS Licensed Engineering Geologist conducted a site-specific landslide hazard investigation that consisted of:

- Reviewing sections of the County Code that address geologically hazardous areas
- Reviewing existing available topographic, geologic, and soils literature and maps
- Analyzing project-specific stereo aerial photographs
- Reviewing project test pit logs and soil samples
- Performing a one day site reconnaissance

According to the County Code, the primary criteria for landslide hazard designations are: presence of pre-existing, known mappable landslides; slope angle; and/or composition of the near-surface soils or rock.

URS created a color-coded map of the study area using an existing USGS 10 meter DTM to segregate slopes into three categories: slopes less than 20%; slopes between 20% and 30%; and slopes greater than 30%. We then superimposed the NRCS soil survey map onto the slope map to provide soil type information. The resulting Landslide Hazard Map is presented as Figure 2.15-1.

Landslide Hazard Area Delineation

Skamania County recognizes three classes of LHAs. Class I (Severe) LHAs are considered to present a severe landslide hazard and are distinguished as areas of known mappable landslide deposits which have been designated landslide hazard areas by the local legislative body. Class II (High) LHAs are areas with slopes between twenty and thirty percent that are underlain by soils that consist largely of silt, clay or bedrock, and all areas with slopes greater than thirty percent. Class III (Moderate) LHAs are areas with slopes between twenty percent and thirty percent not included in Class II.

URS reviewed available geologic and soils literature to develop a landslide hazard classification for the proposed project. An existing published regional geologic map (partially recreated in Figure 3.1-1) indicates a large landslide in the northeast corner of the study area underlying Tower Line C. Review of stereo photographs of the area where the landslide deposits are
mapped, coupled with a site reconnaissance, indicate that there is little geomorphic evidence for landslide activity such as obvious scarps, hummocky or benched terrain, lobate toe areas, or redirected watercourses. No deep subsurface investigations have been carried out at the site to date, but future explorations in support of design for the turbine tower foundations would provide subsurface information regarding the presence of landslide deposits in the area. Based on our preliminary investigation, there does not appear to be any area of the site that meets Skamania County’s criteria for a Class 4-1 LHA.

Class II LHAs are shown in green on Figure 2.15-1. The Class II LHAs at the site are predominantly associated with the steep slopes to the west of proposed Tower Lines A and B. The proposed site access road, West Pit Road, ascends these slopes to reach the site from the Little Salmon River valley. There are also steep slopes to the east of the 7 southernmost Tower Lines A towers, and on both sides of Tower Line C.

### 3.1.6.2 Impacts

Although none of the proposed turbines are located within Class II LHAs, several of the towers along the western side of the project site (Tower Lines A and B) are located along ridgelines with descending slopes that are locally greater than 35 degrees (70%). The heads of some of the drainages along these slopes are arcuate, indicating possible mass-wasting activity such as landslides, debris flows, and/or earthflows. The access road from the Little Salmon River valley to the project site will traverse Class II LHAs.

Based on aerial photo and field observations, the primary mass wasting process below the ridgelines appears to be debris flows and soil creep. No evidence for deep-seated, block failure type landslides was observed. Local surficial creep of near-surface soils is indicated by the presence of pistol-butted trees on some of the slopes, primarily on the descending slope west of the northern portion of Tower Line A. Other slopes have mature conifer stands that indicated little or no soil creep. Further subsurface investigation in support of final tower foundation design would help determine if there are weak rock or soil layers that could contribute to more deep-seated failure of the ridges and provide information on the quality of the rock mass underlying the ridgelines.

It appears that the primary concern for towers located adjacent to the Class II LHAs is the potential for headward erosion of the steep drainages by debris or earth flow processes. Debris flows could potentially damage to the proposed site access road. Erosion rates of these drainages are unknown, but no obvious recent mass wasting features were observed in the aerial photos or during the site reconnaissance.

Class III LHAs have been delineated adjacent to proposed wind turbines along the southern Tower Line A and along Tower Line C. Class III LHAs are not anticipated to have any impact on the proposed facilities due to the robust nature of the proposed foundation designs.

The landslide hazard evaluation identified several areas where the proposed wind turbine generators are located adjacent to slopes that meet Skamania County’s criteria for Class II and Class III LHAs. The proposed site access road will traverse Class II LHAs as well. The primary hazard to the proposed towers appears to be the potential for exposure to headward erosion of
steep drainages on the slopes below some of the tower locations. Exposure of the towers to headward erosion of the steep slope drainages can be minimized by providing maximum possible setbacks from the tops of the steep slopes and/or by siting the turbines along portions of the ridgelines that are above intervening spur ridges. The most critical area of exposure to Class II LHAs is the narrow ridge at the southern portion of Tower Line A. The primary hazard to the access road would be damage sustained due to debris flow or mass wasting. This hazard would not pose an immediate threat to the operation of the towers, but could temporarily limit access to the site. Interruption to site access could be minimized with regular slope monitoring and contingency plans for slope instability (such as alternate access routes and identification of contractors available for emergency assistance).

It is URS’s opinion that the proposed Whistling Ridge Energy Project facilities can be constructed and operated without danger to human life or the surrounding environment due to landslide hazards.

3.1.6.3 Mitigation Measures

At this time, no mitigation measures are anticipated. Additional geotechnical investigations for tower foundation design would provide deeper (> 16 feet) subsurface data. If the additional data indicates potential for slope instability, mitigation would be accomplished through engineering design or avoidance.

3.1.7 EROSION/ENLARGEMENT OF LAND AREA (ACCRETION)

Erosion is the breakdown and transport of soils and bedrock by natural processes, including water, wind, and glaciation. The susceptibility of any material to erosion depends on 1) chemical and physical characteristics (e.g., cohesion); 2) topography; 3) the amount and intensity of precipitation and surface water; 4) the intensity of wind; and 5) the type and density of vegetative ground cover, if present.

The assessment of erosion potential is principally based on the erosion potential specified for the surficial soils by the NRCS (formerly the Soil Conservation Service). The NRCS uses an erosion factor, K, to indicate the susceptibility of a soil to sheet and rill erosion by water. This is one of the six factors used in the Universal Soil Loss Equation to predict the average annual rate of soil loss by sheet and rill erosion. The values of K range from 0.05 to 0.69, with higher K indicating more erosion susceptible soil. K-values below 0.13 are considered to have low potential for erodibility; values in the range of 0.13 to 0.26 are considered medium; and values higher than 0.26 are considered high. The effect of wind erosion is given by grouping the soils into different wind erodibility groups.

3.1.7.1 Existing Environment

Plant Site

The K-values for soil at the proposed development site and access roads are 0.20 for the McElroy and Timberhead gravelly loams, 0.24 for the Undusk gravelly loam, and 0.37 for the Underwood loam (USDA NRCS 1988). These erosion factors indicate that the Underwood loam...
has a high potential for erosion by water and the McElroy, Timberhead, and Undusk units have a medium potential. Most soils found in the site vicinity are classified as having a low susceptibility to wind erosion.

### 3.1.7.2 Impacts

**Plant Site**

The potential for erosion or aggradation related to the planned development would be greatest during and immediately after the construction process. The NRCS classifies surficial soils at the site as generally having medium erosion potential. During the dry season, soils that are disturbed and stripped of vegetative cover may be susceptible to wind erosion. The potential for erosion by wind and water would be minimized through the use of erosion control measures to be outlined in the SWPPP as described in Section 2.10.

### 3.1.7.3 Mitigation Measures

BMPs and other measures would be taken to mitigate the erosion hazard at the project site.

Erosion control measures for construction at the site are outlined in Sections 2.10.2 and 2.14.1. The sequences and methods of construction activities would be controlled to limit erosion and are summarized below:

- Construction activities would be controlled to help limit erosion. Clearing, excavation and grading would be limited to those areas of the project absolutely necessary for construction of the project. Areas outside the construction limits would be marked in the field and equipment would not be allowed to enter these areas or to disturb existing vegetation.

- The construction contractors would implement the EFSEC-approved Erosion and Sedimentation Control Plan during construction to minimize soil loss due to surface water flows.

- The EFSEC-approved Environmental Protection Control Plan would be implemented to provide adequate maintenance and inspection of the erosion and sediment control system. The plan specifies that control structures would be inspected at a frequency sufficient to provide adequate environmental protection. Such inspections would increase in frequency during rainfall periods. In addition, supplies including sandbags and channel-lining materials would be stored on site for emergency use.

- Surface runoff would be diverted around and away from cut and fill slopes and conveyed in pipes or protected channels. If the runoff is from disturbed areas, it would be directed to a sediment trap prior to discharge.
SECTION 3.2 AIR  
(WAC 463-60-312)

3.2.1 AIR QUALITY

Air quality in Washington is typically regulated by several agencies. In Skamania County, the Southwest Region Clean Air Agency is typically the local authority for air quality permitting of industrial sources, and permits minor sources through the Notice of Construction permit process. Ecology generally retains the authority for air quality permitting of major sources in attainment areas through the Prevention of Significant Deterioration (PSD) permit process. The United States Environmental Protection Agency (EPA) also has a role in the PSD process and in ensuring all states have plans in place to maintain compliance with ambient air quality standards.

The fuel source for the Whistling Ridge Wind Energy Facility would be wind that is transformed from kinetic energy into electrical energy by wind turbine generators. No air emissions would be generated from operation of the wind turbine generators at the project. The operation of the project would have no effect on the climate (visible plumes, fogging, misting, icing, or impairment of visibility, and changes in ambient levels caused by emitted pollutants). There would no emissions from the operation of the project, and thus none to be regulated. There are no areas within Skamania County that are currently designated as non-attainment areas for air quality. For a description of the meteorological conditions at the site, see Section 2.1.3.2, Climate.

In recent years, many of the new power plants proposed and constructed in the Pacific Northwest have been fossil fuel fired plants, primarily using natural gas as fuel. Fossil fuel fired plants, in contrast to wind power projects, emit significant quantities of the carbon dioxide that is the primary cause of anthropogenic climate change. Natural gas fired plants also emit sulfur oxides and nitrogen oxides, which contribute to both ground-level air quality problems and acid rain. By producing electricity without generating air emissions, which would otherwise be produced by fossil fuel fired plants, the project would have a significant beneficial impact on overall air quality and climate.

3.2.2 CONSTRUCTION EMISSIONS

Construction of the project would result in temporary air emissions from the following sources:

- Exhaust from the diesel construction equipment used for project site preparation, grading, excavation, and construction of on-site structures
- Exhaust from water trucks used to control construction dust emissions
- Exhaust from diesel trucks used to deliver equipment, concrete, fuel, and construction supplies to the construction site
• Exhaust from pickup trucks and diesel trucks used to transport workers and materials around the construction site and from vehicles used by workers to commute to the construction site

• Exhaust from diesel-powered welding machines, electric generators, air compressors, etc.

These emissions would be similar in nature to those produced by any construction project that involves heavy equipment and transportation of materials to the project site.

3.2.3 OPERATION EMISSIONS

Operation of the project would produce no air emissions as no fuel would be burned to produce energy. Operation of the project would therefore have no negative impact on air quality. According to the EPA, air emissions from fossil fuel combustion for electricity production are a leading source of air pollution nationally, accounting for:

• 67% of sulfur dioxide emissions

• 28% of nitrogen oxide emissions

• 36% of carbon dioxide

• 3% of mercury

The most likely alternative to wind energy generated by the project would be electricity generated from the combustion of fossil fuels. Fuel combustion from electric utilities generated 6.6 million tons of carbon monoxide and 6.0 million tons of nitrogen oxides in 2006. Total fossil fuel combustion produced 5,638 million metric tons carbon-equivalent of carbon dioxide in 2006 (EPA 2008).

As the energy produced by the project would displace the need for other energy produced by fossil fuel combustion, operation of the project would have a positive effect on air quality and climate change by reducing overall air emissions.

3.2.4 ODOR

Construction of the project would produce limited odors associated with exhaust from diesel equipment and vehicles. Mitigation efforts are described in Section 3.2.6, Mitigation Measures.

Operation of the project would create no odors as no combustion is involved and no odor-producing materials would be used in project operations.

3.2.5 DUST

Construction of the project would create fugitive dust emissions from construction-related traffic and additional wind-blown dust as a result of ground disturbance. Whistling Ridge Energy LLC would implement an effective dust control program to minimize any potential disturbance from
construction-related dust. Dust suppression would be accomplished through application of either water or a water-based, environmentally safe dust palliative such as lignin. The use of a dust palliative such as lignin (a non-toxic, non-hazardous compound derived from trees) would result in the use of substantially less water for dust suppression and therefore less traffic from water trucks to the construction site. The final decision regarding dust suppression techniques would be made by the EPC contractor in consultation with local authorities.

Operation of the project would result in minimal or no increase in dust levels. Project related-traffic increases on gravel access roads would generate small amounts of additional fugitive dust. This increased traffic would consist largely of weekly or less frequent trips to turbines in service vehicles for maintenance and repair activities.

### 3.2.6 MITIGATION MEASURES

The following mitigation measures for construction-related air emissions and dust are proposed:

- All vehicles used during construction would comply with applicable Federal and state air quality regulations
- Operational measures would be implemented, such as limiting engine idling time and shutting down equipment when not in use
- Active dust suppression would be implemented on unpaved construction access roads, parking areas and staging areas, using water-based dust suppression materials in compliance with state and local regulations
- Traffic speeds on unpaved project roads would be kept to 25 mph to minimize dust generation
- Carpooling among construction workers would be encouraged to minimize construction-related traffic and associated emissions
- Disturbed areas would be replanted or graveled to reduce wind-blown dust
- Erosion control measures would be implemented to limit deposition of silt to roadways

Mitigation measures for construction impacts are described in greater detail in Section 2.3, Construction on Site, and Section 1.4, Mitigation Measures.

No mitigation is proposed for project operations, as there would be no air or odor emissions.
SECTION 3.3 WATER
(WAC 463-60-322)

Project operation would require water use primarily for the Operations and Maintenance building. When the project is operational, there would be eight to nine permanent full-time and/or part-time employees on the Operations and Maintenance staff. The average total water supply needs would be less than 5,000 gpd.

A well would be drilled to provide potable water for the bathroom and kitchen in the Operations and Maintenance building. All water would be discharged to a septic tank installed on site. There would be no process water generated on site, so no water associated with plant operations would be discharged to surface waters. The project would have negligible impacts on surface water and groundwater resources in the vicinity.

Stormwater runoff drains to open land and the ephemeral and perennial streams that flow either westward toward the Little Salmon River or eastward toward the White Salmon River. Stormwater is conveyed to these streams via ditches and culverts.

3.3.1 SURFACE WATER RESOURCES (MOVEMENT/QUALITY/QUANTITY)

3.3.1.1 Existing Surface Water Conditions

The project area is generally mountainous with steep-sided narrow drainages. Elevations of the turbine positions generally range from 2,100 feet to 2,300 feet above msl. The Columbia River flows south of the site and receives runoff via the White Salmon drainage area from the east portion of the site and via the Little White Salmon Basin from the west portion of the site.

USGS review identified one undelineated wetland occurring outside the impacted area, west of turbine E3. This wetland is labeled as “Cedar Swamp” on the USGS topographic map (Figure 3.3-1). Five intermittent drainage ways were identified on the map at the northeastern portion of the project area. Three of the drainage ways drain to Cedar Swamp from the north. The remaining two drainage ways are to the south of Cedar Swamp, and ultimately drain intermittently to Little Buck Creek, a perennial stream that is outside of the project area to the east. The planned improvements to existing roads that would occur inside the Scenic Area would cross one intermittent stream (shown on Figure 3.3-1). This stream has no defined channel and carries water only during runoff events. It is classified as a Class V stream under SCC 21.04.020(B).

The project area soils are classified as well-drained, with slow to moderate runoff, and slight to moderate hazard of water erosion. The presence of scour, sedimentation, steep slopes, ephemeral and perennial streams, and the soil classifications suggest that surface water runoff and infiltration within the project are moderate (Haagen 1990). Water runoff from the northeast area of the project drains southeast via Cedar Swamp and tributaries to Little Buck Creek before flowing south to the White Salmon River, and ultimately to the Columbia River. Water runoff from the southwest area of the project drains west and southwest to a flat area east of the project, ultimately draining to the Columbia River.
Revised Figure 3.3-1

Waterways in the Project Vicinity

Source: GeoDataScape.

Whistling Ridge Energy Project
Skamania County, Washington
The proposed access road, West Pit Road, crosses one unnamed drainage in the Lapham Creek watershed. This stream had observed flow through the existing culvert under West Pit Road at the time of the July 2009 field visit. However, the surface flow and the channel disappear downstream of the culvert. There is no surface water connection to Lapham Creek.

3.3.1.2 Impacts to Surface Water

No wetlands or other surface water bodies are proposed to be filled as a result of the project. Wetlands are discussed in further detail in Section 3.5, Wetlands.

The planned improvements to existing roads that would occur inside the Scenic Area would cross one intermittent stream, unnamed drainage which currently flows under West Pit Road through a culvert (Figure 3.3-1). This stream has no defined channel and carries water only during runoff events downstream of the culvert. It is classified as a Class V stream under SCC 21A.04.020(B) Appendix C. Buffers are established for Class V streams. However, expansion of existing uses is allowed within these water resource buffers. Development review would be required under SCC 21A.05 and SCC 21A.06 in Fish and Wildlife Protection Areas and Geologically Hazardous Areas in consultation with WDFW. However, existing roadways would be allowed without review. The road improvements in these regulated fish and wildlife protection areas do not exceed the allowed expansion threshold. For a full discussion of fish, wildlife, their habitats, and project impacts to these, please see Section 3.4.

The impacts to surface water relating to site drainage during and following construction are expected to be minimal. The highest risk of construction-related impacts to surface water quality is expected to be associated with the construction and improvement of new and existing roadways. These activities are expected to disturb the largest areas, exposing soils in potentially steep areas. Roadway improvements to West Pit Road would be needed. The culvert under West Pit Road through which the unnamed drainage flows would be maintained however would likely be extended along with the roadway widening. The highest priority for these activities would be to control erosion and sedimentation. A SWPPP would be developed for the project, consisting of structural and non-structural BMPs, to minimize the potential for discharge of pollutants from the site during and after construction activities.

The SWPPP would be developed to meet the requirements of the Ecology General Permit to Discharge to Stormwater pollution control program associated with construction activities. Examples of structural BMPs included in the SWPPP to be implemented during construction activities are the installation of silt curtains, mats, hay bales, check dams, silt traps, and other methods for controlling and diverting runoff away from exposed soils or areas susceptible to erosion. Examples of non-structural BMPs to be included in the SWPPP are management practices for handling and disposing of materials, as well as spill prevention. BMPs associated with construction are discussed in further detail in Section 2.10, Surface Water Runoff.

Stormwater would be conveyed through roadside ditches, discharging to existing on-site drainage ways. New culverts would be constructed in the newly constructed roads, where required, to convey runoff toward the existing drainage ways, and existing culverts would be
replaced to better accommodate seasonal flow regimes of intermittent streams crossing roadways. Culvert outlets to natural channels would be armored to control erosion and scouring of site soils. Permanent vegetation would be established and other permanent BMPs would be used to control erosion and sedimentation. With all permanent stormwater BMPs in place, operation-related impacts to stormwater are expected to be minor.

The amount of chemicals kept on site would be very minimal, and all would be located at the Operations and Maintenance building, under cover. An SPCC Plan would be developed and kept on site for the prevention and response to spills.

### 3.3.1.3 Mitigation Measures

Permanent BMPs would be designed and incorporated into the final construction plans and specifications prepared by the site civil design engineer. These permanent BMPs would include erosion and sediment control through site landscaping, grass, and other vegetative cover. All final designs would conform to the applicable Stormwater Management Manual. Non-structural BMPs also would be incorporated into the operations manual including good housekeeping, preventative and corrective maintenance procedures, steps for spill prevention and response, employee training, and inspection and record-keeping procedures.

### 3.3.2 RUNOFF/ABSORPTION

#### 3.3.2.1 Existing Runoff/Absorption Conditions

As discussed in Section 3.3.1.1, site soils are well-drained with slow to moderate runoff and slight to moderate hazard of water erosion. This infers that currently there is both moderate stormwater runoff and infiltration onsite.

#### 3.3.2.2 Impacts to Runoff/Absorption

The current site is not developed, with the exception of private, gravel logging roads, and is composed of well-draining soils. The construction of the Whistling Ridge Energy Project would involve roadway improvements on approximately 7.27.9 miles of existing private, gravel logging roads, construction of about 2.4 miles of new gravel access roads, the project substation, an Operations and Maintenance building, the collector system pad, a pad for each turbine tower, and underground electric cables buried in trenches along the access roads. Temporary roadways would be built to provide additional access for heavy machinery during construction.

As a result of permanent improvements, site surface water runoff is expected to increase slightly. However, since the increased area of impervious surfaces is small compared to the total project area (estimated at less than 1 acre), these impacts are expected to be minimal. Stormwater would continue to be routed off site via culverts and some stormwater would continue to infiltrate in the way it does currently. Based on the conditions and implementation of BMPs, the net impact to absorption on the site is considered negligible. No negative impacts on runoff and no negative impacts on adjacent surrounding properties are anticipated as a result of the permanent site improvements. See Section 2.10, Surface Water Runoff for further detail of permanent improvement areas.
3.3.2.3 Mitigation Measures

The required BMPs are expected to: minimize erosion, control sedimentation, prevent run-on of stormwater onto disturbed areas, and prevent runoff from disturbed areas. One measure may be treatment of stormwater exiting disturbed areas. Construction-phase erosion and sedimentation control BMPs, as described in Section 2.10, Surface Water Runoff, would be implemented to mitigate the expected impacts of soil disturbance. These may include chemical source control, silt fencing, stabilized construction entrances, street sweeping, straw bale check dams, and rock check dams. With implementation of BMPs, no negligible impacts on runoff or on adjacent surrounding properties are anticipated during construction activities. Construction BMPs are described in further detail in Section 2.10, Surface Water Runoff.

Permanent, operations-phase runoff control and water quality enhancement BMPs, also described in Section 2.10, Surface Water Runoff would be implemented to mitigate the expected impacts of increased runoff rate and pollution from vehicle traffic. These BMPs would include stabilized landscaped areas and vegetated ditches or swales, and would provide the necessary control of stormwater runoff.

3.3.3 FLOODPLAINS

3.3.3.1 Existing Conditions

The project area is located outside the 100-year floodplain for the Little White Salmon and Columbia Rivers as currently mapped by FEMA. The project site is located on a series of north trending ridges that range in elevation from approximately 2,100 to 2,300 feet above msl. The land west of the proposed project site drops sharply to a narrow river terrace and then to an elevation of less than 800 feet above msl in the Little White Salmon River valley. Because the current elevation of the site is above the 100-year floodplain, additional mitigation measures for flooding are not planned.

3.3.3.2 Potential for Flooding and Protective Measures

Because the site is above the 100-year floodplain, an evaluation of the change in surface water elevation created by the additional fill placed for site development would not be necessary.

3.3.4 GROUNDWATER RESOURCES

This section describes the hydrogeologic resources at the Whistling Ridge Energy Project site, project impacts, and mitigation.

3.3.4.1 Hydrogeologic Setting

The project site is located approximately 7 miles west of the town of White Salmon, Washington, and approximately 2 miles east of the Little White Salmon River. A subsurface investigation was conducted in September 2007, which included twelve test pits excavated from seven to 16 feet in depth to assess near-surface soil and rock characteristics. Surficial soils are primarily characterized as soft, moist sandy silt to clay with sand, and clayey sand. Immediately

Whistling Ridge Energy Project
EFSEC Amended Application 2009-01

3.3-5

October 12, 2009
beneath the unconsolidated soils, rock with variable strength and weathering properties is present. The test pit data is limited to depths no greater than 16 feet bgs. It is anticipated that rock quality of basalts would improve with depth but that weaker interflow zones consisting of volcaniclastic material and paleosols are possible at any depth. The bedrock underlying the proposed project site consists of Grande Rhonde Basalt of the CRBG and Quaternary basalt of Underwood Mountain. Groundwater was not encountered up to a depth of 16 feet bgs during subsurface exploration. However, these observations reflect groundwater levels at the time of the field investigation and actual groundwater levels may fluctuate significantly in response to seasonal effects, regional rainfall, and other factors not observed during this investigation. Regional or perched water tables may be present at a greater depth.

3.3.4.2 Impacts to Groundwater Resources

Operation of the project would have minimal impacts to groundwater. For operations, a well would be installed by a licensed installer to serve the Operations and Maintenance facility. A well using less than 5,000 gallons of water a day, and thus exempt from permit requirements in RCW 90.44.040, would be installed to provide water for use to the Operations and Maintenance building. The well would be installed by a well contractor licensed pursuant to Chapter 173-162 WAC, and in compliance with the requirements and standards of Chapter 173-160 WAC. The well would be installed consistent with Skamania County Community Development Department and Ecology requirements for the new wells. This well would provide water for bathroom and kitchen use and is expected to consume less than 5,000 gpd. It is unlikely that the project water use would have a direct effect on groundwater quantity, quality, and flow direction in the immediate area below the proposed facilities. Although the impervious surfaces would increase slightly with the construction of the project, they are not expected to be significant enough to notably affect the water recharge and runoff on site. Therefore, impacts to the hydrologic setting within the Whistling Ridge Energy Project site are considered negligible.

3.3.4.3 Mitigation Measures

No impacts have been identified regarding the quantity of water infiltrating the site following construction. BMPs that are recommended for site development include stabilized landscaped areas and vegetated ditches or swales.

Storage of chemicals onsite is minimal; however, the site development plan would require an SPCC Plan that would protect groundwater (See Section 2.9, Spillage Prevention and Control). Therefore, mitigation for groundwater quality impacts is not necessary.

3.3.5 PUBLIC AND PRIVATE WATER SUPPLIES

3.3.5.1 Existing Conditions and Water Authorization

The Pleistocene epoch (1.8 million years to 10,000 years BP) basalts and cinders erupted from the Underwood Mountain vents and overlie the Tertiary CRBG Grande Ronde and Wanapum basalts. Public records of wells located within the Underwood volcanic field indicate a 310-foot thick repetitive sequence of thin lava flows (two to eight feet thick), cinders and silty-clays overlying a productive confined aquifer consisting of intensely fractured Grande Ronde basalt.
The Miocene-epoch Grand Ronde Basalt consists of multiple basalt flows that are a subgroup of the CRBG, and has been described to have a thickness of up to 1,000 feet, although the thickness in the project vicinity is not known. There are no public water supplies within the project area.

### 3.3.5.2 Impacts to Public and Private Water Supplies

**Water Usage**

As described earlier, water use during operations is expected to be less than 5,000 gpd and would be provided by a well that would be drilled on site. Water use is expected to be consistent year-round.

**Water Supply During Construction**

Water used during construction would be primarily associated with road construction, wetting of concrete, dust control, and other activities. Water consumed during construction activities would be purchased by the contractor from an off-site vendor with a valid water right and transported to the site in water-tanker trucks. No water would be used from the site during construction. There would be no water treatment requirements or methods on site. Environmentally benign dust palliatives such as lignin may be added to water used for dust suppression to improve efficiency and reduce water use.

**Future Conditions**

The well that would be drilled for the project, and its associated use of less than 5,000 gpd, is not expected to impact water levels in private wells in the vicinity of the project. There are no public water supplies within the project area; therefore, no impacts are anticipated to public water supplies.

### 3.3.5.3 Mitigation Measures

No impacts to public water supplies and no adverse impacts to private water supplies (water wells) are expected. Therefore, no mitigation measures are required.
SECTION 3.4 HABITAT, VEGETATION, FISH AND WILDLIFE  
(WAC 463-60-332)

3.4.1 HABITAT AND VEGETATION

This section describes existing habitat and vegetation resources within the Whistling Ridge Energy Project site, the potential impacts of the proposed project on these resources, and the mitigation planned for the project.

3.4.1.1 Existing Conditions

The project site is located in the Southern Washington Cascades Province, within the grand fir (Abies grandis) and Douglas-fir (Pseudotsuga menziesii) major vegetation zones (Franklin and Dyrness 1988). Topography in the area is characterized by generally accordant ridge crests, separated by steep, deeply dissected valleys. The prevailing climate is cool and wet. The majority of precipitation falls as snow, which may accumulate one to three meters during the winter season.

Whistling Ridge Energy Project Site

The proposed Whistling Ridge Energy Project site is located on Underwood Mountain, northwest of White Salmon, Washington. The project site, which includes turbine strings, access roads, laydown staging areas, the operations and maintenance facility, and substation, measures 1,152 acres. Major drainages in the vicinity of the project site include the White Salmon Basin to the east and the Little White Salmon River Basins to the west, both of which drain to the Columbia River, which is located south of the project site.

Historically, the project site was dominated by grand fir and Douglas-fir. The relative abundance of each of these coniferous species was driven by elevation, aspect, underlying soil, and previous disturbance history (Franklin and Dyrness 1988). Mixed conifer and deciduous forest stands were present, typically following natural disturbance events. Deciduous forests also were present, composed mainly of alder (Alnus rubra, A. viridis ssp. sinuata), Pacific dogwood (Cornus nuttallii), and big-leaf maple (Acer macrophyllum).

For the last century, the predominant land use in the area located between Underwood Mountain and the Little White Salmon River has been commercial forest production. Lands within the project site are privately owned, and have been actively-managed for timber for the last century. As a result of ongoing timber harvest, forests within the project site are characterized by a mosaic of stand ages; however, average stand age has declined as a result of relatively short stand rotations. Forest management practices have resulted in a shift in species dominance to the commercially valuable Douglas-fir. Changes in stand structure and complexity, patch size, and species distribution also have occurred. Few large, old-growth conifers exist in the vicinity of the project site, and there are no known late-successional stands within or adjacent to the project site. A linear clearing associated with a high voltage transmission line corridor traverses the southern portion of the project site in an east-west axis. Canopy species within the corridor have been removed, and areas are managed to be devoid of shrub and tree species. The project site
contains a network of roads ranging in width from approximately 8 to 12-20 feet. These roads are currently used to support logging activity and for accessing BPA transmission lines. Existing roads within the project site can be accessed from County roads extending north from SR 14.

Habitat, vegetation, and rare plant surveys were conducted within the Whistling Ridge Energy Project site in 2003. Environmental assessments included a pre-field information review and field surveys designed to classify habitats and identify rare plants that may occur within the project site.

**Habitat Types**

Habitat maps were created by CH2M Hill (Figure 3.4-1). Existing data was obtained from Washington Natural Heritage Program (WNHP) and through discussions with the USFWS. Habitats were identified using WDNR orthophotos from January 2002 and classified using the US Forest Service Classification System (USFS 1985). Habitat maps were field-verified during the 2003 plant survey season. These data were entered into a GIS database and used to calculate the total acres of each habitat type that would be crossed by the proposed project elements. The results of the habitat survey are provided in the Vegetation Technical Report (Appendix B-1).

Five vegetation communities and wildlife habitats were identified within the project site:

- Grass-Forb Stand (recent clearcuts)
- Brushfield/Shrub Stand
- Conifer-Hardwood Forest
- Conifer Forest
- Riparian-Deciduous Forest

**Grass-Forb Stand.** Grass-forb stands are defined as habitats where shrubs comprise less than 40 percent crown cover and are less than 5 feet tall (USFS 1985). This stand type typically occurs when a natural or anthropogenic disturbance such as a wildfire, wind, or timber harvest results in the removal or death of the majority of large trees, or when brushfields are cleared for planting. These habitats may be devoid of vegetation, or covered by herbaceous grasses and forbs. Tree regeneration in grass-forb stands is typically less than 5 feet tall and 40 percent crown cover.

Grass-forb stands within the project site are primarily located in recently clearcut harvest areas. Vegetation in these areas is minimal and consists predominantly of weedy herbaceous species, including bull thistle (*Cirsium vulgare*), Canada thistle (*Cirsium arvense*), and dandelion (*Taraxacum officinale*). Coarse woody material (CWM), occasional slash piles, and large areas of bare ground are common in these areas.
**Brushfield/Shrub Stand.** Brushfields are defined as the shrub-dominated habitats (USFS 1985). These habitats typically develop following clearcut harvest, or natural disturbance that may result in removal of vegetation.

The majority of brushfields are young plantations that have been planted with Douglas-fir. The plantations typically have not reached the closed-canopy stage. Vegetation consists of remnant forest understory species, such as vine maple (*Acer circinatum*), Sitka alder, beaked hazelnut (*Corylus cornuta* var. *californica*), serviceberry (*Amelanchier alnifolia*), oceanspray (*Holodiscus discolor*), bracken fern (*Pteridium aquilinum*), sword fern (*Polystichum munitum*), and early successional species such as Himalayan blackberry (*Rubus armeniacus*), fireweed (*Epilobium angustifolium*), common yarrow (*Achillea millefolium*), pearly everlasting (*Anaphalis margaritacea*), and grasses. Large amounts of bare soil, slash and other logging debris are common.

Vegetation control has occurred in some areas as part of existing forest management practices. Control methods include herbicide application and/or mechanical control. Areas where vegetation management has occurred are visually and functionally different from areas where control has not been implemented. In areas where vegetation control has not occurred, dense vine maple thickets with occasional alder or Douglas-fir frequently occur. Patches of alder saplings, salmonberry (*Rubus spectabilis*), vine maple, red elderberry (*Sambucus racemosa*), oceanspray, lupine (*Lupinus* spp.), Oregon oxalis (*Oxalis oregana*), and grass also may be present in these areas. Small diameter CWM is common.

**Conifer-Hardwood Forest.** Conifer-hardwood forests within the project site are predominantly characterized by the presence of bigleaf maple and Douglas-fir, with some red alder. The forest stand condition is characterized as a multi-layer, closed sapling-pole forest (USFS 1985). Canopy height ranges from 40 to 60 feet, and canopy closure is between 60 and 80 percent. The majority of canopy cover results from the presence of Douglas-fir (~70 percent). The shrub layer is characterized by vine maple, salmonberry, thimbleberry (*Rubus parviflorus*), red elderberry, beaked hazelnut, and Pacific dogwood. Density of the shrub layer is variable. The herbaceous layer is characterized by sword fern, trailing blackberry (*Rubus ursinus*), oxalis, grasses, and moss. CWM is generally low to moderate. Deciduous snags are more common than conifer snags; however, short well-decayed conifer snags may be present.

**Conifer Forest.** Coniferous forests located within the project site are dominated by grand fir and Douglas-fir. Forest stand condition is primarily closed sapling-pole-sawtimber and large sawtimber. The diameter at breast height (dbh) of pole-size conifers measures 8–12 inches. The dbh of sawtimber measures 12 to 23 inches. Closed sapling-pole-sawtimber stands are characterized by closed canopy, relative short live crowns, and exclusion of shrub species and many forb species. CWM in these stands is typically low, consisting mainly of remnants from historic forests. Snags are rare; however, small diameter snags become more common in the pole and sawtimber stages, as smaller individuals are out-competed.

Large sawtimber is considered to be at least 21 inches in dbh. Large sawtimber stands are characterized by within-stand differentiation of canopy species, the emergence of dominant trees,
and a more diverse and multilayer understory composed of shrubs and forbs. Snags and CWM are generally rare; however, this may vary depending on past harvest practices, stand management, and actual stand age.

The majority of coniferous forests within the project site is managed for commercial timber production, and is replanted following harvest. Commercial timber lands are widespread throughout the vicinity of the project site.

**Riparian Deciduous Forest.** Riparian deciduous forests may develop in near-stream areas as a result of natural or anthropogenic disturbance. Riparian deciduous forest habitats are present within the project site in an area known as “Cedar Swamp”. Historically this area was dominated by large, old-growth western redcedar (*Thuja plicata*); however, these trees have since been harvested. Cedar Swamp is now dominated by willow (*Salix sp.*) and cottonwood (*Populus balsamifera*), with scattered occurrences of young western redcedar.

The vegetation communities described above are common throughout the Southern Washington Cascades Province. In the proposed project site, these communities are primarily maintained through forest management. Because the project is located within private commercial timber lands, existing forest management practices are expected to continue for the foreseeable future. The total acreage of each habitat type was calculated during the 2003 surveys; however, because of active forest rotation schedules, some of these areas have been harvested. Aerials photos from 2008–2009 were used to update the habitat maps from 2003 with recent timber harvests. The updated acreages of each habitat type can be found in Table 3.4-1 and are shown on Figure 3.4-2.

**Rare Plant Species and Vegetation Communities**

Several sources were used to identify special-status plants that have been documented or have the potential to occur within the vicinity of the proposed project, including:
- Federal-listed or proposed as a rare, threatened, or endangered species in Skamania County (USFWS 2009)
- A WNHP record search of known rare plant locations in the vicinity of the project site (WNHP 2003a)
- *Rare Plant List for Skamania County* (WNHP 2003b)

These data indicated that no federal-listed plant species are known to occur in the vicinity of the project site. However, four rare plants occur within two miles of the project site, including branching montia (*Montia diffusa*), Suksdorf’s desert parsley (*Lomatium suksdorfii*), Siskiyou false hellebore (*Veratrum insolitum*), and golden chinquapin (*Chrysolepis chrysophylla*). Two additional rare plant species are reported as historically occurring in the vicinity of the project site, including bolandra (*Bolandra oregana*) and white-top aster (*Aster curtus*). Three occurrences of the Oregon white oak/Idaho fescue (*Quercus garryana/Festuca idahoensis*) vegetation community, a Known High-Quality or Rare Plant Community and Wetland Ecosystem of Washington, are documented within two miles of the project site (WNHP 2003a). These are located along the Columbia and White Salmon Rivers. No additional rare plants sites have been recorded in the vicinity of the project site since the rare plant surveys were conducted in 2003 (WNHP 2009).

Surveys were conducted in May and June 2003, and followed methods described in the Bureau of Land Management (BLM) Survey Protocols for Survey and Manage Strategy 2 Vascular Plants (Whiteaker et al. 1998). Survey dates were selected to encompass all or a portion of the blooming times of all rare plants potentially occurring in the project site. All surveys were completed by CH2M HILL. Surveys were conducted within a 300-foot corridor centered on proposed turbine strings and associated access roads, and a 100-foot corridor centered on existing roadways that were identified as needing improvement. Rare plant surveys also were conducted in proposed locations for the Operations and Maintenance facility, substation, and staging areas. No rare plant or habitat surveys were conducted on County roads used to access the site or along the underground cable routes. However, much of this area has been harvested recently and does not contain rare plant habitat.

No rare plant species or plant communities were detected on the project site. A detailed account of survey methods and results can be found in the Rare Plant Survey Report (Appendix B-2). A list of plant species observed during vegetation surveys also can be found in Appendix B-2.

Because turbines have been added and removed from the initial alignment, field surveys conducted prior to the March 2009 Application submittal (Figure 3.4-3) may not cover 100% of the proposed wind farm. Additional surveys are planned for were conducted in May and July 2009 to supplement the previous studies and would included County roads and underground cable routes where potential rare plant habitat could exist.
**Noxious Weeds**

The project site contains several noxious weed species, which are nonnative, invasive plants. The weed species observed during field visits to date are listed in Table 3.4-2.

<table>

The Washington Noxious Weed Control Board identifies lists of noxious weed species that require control, eradication, or monitoring. Class A noxious weeds are nonnative species with a limited distribution within a state and require eradication to reduce the potential of becoming more widespread.

Class B noxious weeds are regionally abundant, but may have limited distribution in some counties. In Washington, in regions where a Class B noxious weed is unrecorded or of limited distribution, prevention of seed production is required. In these areas the weed is a “Class B designate.” However, in regions where a Class B species is already abundant or widespread, control is a local option. In these areas the weed is a “Class B non-designate.”

Class C noxious weeds are already widely established, but placement on the state list allows counties to enforce local control if desired.

**Improved Roadways outside the Site Boundary**

Access to the proposed project site from SR 14 would require traversing lands located within the Columbia River Gorge National Scenic Area, then via Cook-Underwood Road to Willard Road, and then via a new direct connection to West Pit Road, an existing private logging road. Approximately 2.5 roadway miles in this area would require minor improvements as a result of the proposed project. This improved West Pit road is owned and operated by S.D.S Co., LLC, and would be used to connect existing County roads within the Scenic Area to project roads owned by S.D.S Co., LLC on the project site. In addition, four existing roadway intersections in the Scenic Area would require slight modification to accommodate transportation.
of the large turbine segments (Figure 4.3-2). These intersections have not been surveyed for habitat or rare plants. Surveys are planned for spring habitat and rare plants were conducted in May and July 2009 and none were found.

### 3.4.1.2 Impacts

**Whistling Ridge Energy Project Site**

*Habitat Types*

Construction and operation of the Whistling Ridge Energy Project would require the removal of vegetation in some areas to accommodate roadway construction and improvement, turbine siting, staging, and construction. Each turbine footings and foundations would measure approximately 3,100 square feet. Vegetation surrounding each turbine would be managed according to the following specifications:

- A circular area extending 50 feet from each turbine would be harvested and graveled
- From 50 feet to 150 feet from the base of the turbines, tree heights would be limited to 15 feet above the elevation of the base of the turbine
- From 150 feet to 500 feet from the base of the turbines, tree heights would be restricted to 50 feet above the turbine base within an area formed by a 90 degree arc centered on the ordinary downwind direction

The A and F turbine strings and parts of the B and C turbine strings would be accessed by existing roads. Modifications to these roads are anticipated in order to support the long and heavy loads required for delivery of the wind turbine systems. An estimated 5.1 miles of roads within the project site would require improvements as a result of the proposed project. The majority of new roads would be constructed to access parts of the B and C turbine strings, and all of the D and E turbine strings. Access to these turbines would require 2.4 miles of new roadway. All roads used to access turbines would be maintained throughout the life of the project.

All vegetation clearing would be completed using crawler tractors, rubber-tired skidders, mobile feller-bunchers, or cable yarding equipment. This equipment is typically used in timber harvest, and is currently used to harvest other mature stands located on S.D.S. Co., LLC property. Logs would be transported by truck to SDS Lumber Company facilities in Bingen, Washington. Except for maintained and permanently cleared areas, cleared areas would be replanted with trees within one year following completion of construction (typically the following spring). Areas where trees are permanently removed would be replanted with appropriate native grasses and low-growing shrubs. Because it is being implemented for the purpose of the project, cleared areas would be considered “forest conversion” under the Washington Forest Practices Act. However, cleared areas would still be reforested in accordance with typical commercial forestry management practices when feasible.

Permanent and temporary impacts to habitat types within the project site can be found in Tables 3.4-3 and 3.4-4.

c. The permanent impact area of proposed development within the area encompassed by a 100-foot corridor along all project transmission lines. Does not include overlap of road corridor or turbine corridor.

**Rare Plant Species and Vegetation Communities**

Because no rare plants were identified in the portion of project site surveyed to date, no project-related impacts are anticipated to any federal- or Washington State-listed plant species during construction or operation of the proposed project. Impacts to habitats are expected to vary depending on the location and quality of habitat. Mature forests within the project site would be harvested to accommodate the facility. However, timber harvest in these areas would occur in the absence of the proposed project based on existing harvest rotation schedules.
**Noxious Weeds**

While no Class A weeds have been observed in the project area, several Class B and C weeds are present. Constructing the project can foster the spread of noxious weeds throughout the project area. New roads are a pathway for weeds to invade. Many weeds are adapted to disturbed conditions and can establish immediately after construction. Increased traffic also can lead to the spread of weeds. Noxious weeds can threaten the general ecological health and diversity of native ecosystems. Noxious weed infestations are the second leading cause of wildlife habitat degradation. Noxious weeds would be managed within the project site. By implementing BMPs, weeds are not anticipated to spread further as a result of the development of the wind energy facility.

**Improved Roadways outside the Site Boundary**

A total of 2.4-2.5 roadway miles located outside the proposed project site would require upgrades as a result of the proposed project. These roads, West Pit Road traverses forests of varying stand age. Half of the upgraded roads are adjacent to areas characterized by recent clearcut harvest. Road improvements are expected to have negligible impact on habitat and vegetation. Preliminary assumptions of the degree of anticipated impact will be verified during 2009 field surveys.

In addition, four existing roadway intersections in the Columbia River Gorge National Scenic Area would require slight modification to accommodate transportation of the large turbine segments. These intersections have not been surveyed for habitat or rare plants. However, the impact areas for most of these modifications would be immediately adjacent to the road in previously disturbed areas and do not appear to contain natural habitat conditions. Preliminary assumptions of the degree of anticipated impact would be verified during 2009 field surveys.

**3.4.1.3 Mitigation Measures**

Mitigation for potential impacts resulting from the proposed project includes the following:

- The applicant has commissioned extensive studies by qualified biologists of rare plants and habitats at the project site to avoid impacts to sensitive populations. The results and recommendations of these studies have been incorporated into the proposed design, construction, and operation of the project. In the event that the final project layout includes areas that contain suitable habitat for rare plants which have not previously been surveyed, an additional rare plant survey would be conducted at the appropriate time of year.

- The turbine strings have avoided sensitive riparian areas.

- Locating wind turbines in an actively-managed commercial forest avoids impacts to higher quality habitats.
• To the extent possible, new road construction and associated habitat impacts have been minimized by improving and using existing roads instead of constructing new roads.

• Use of certified “weed free” straw bales during construction to avoid introduction of noxious weeds

• All temporarily disturbed areas would be reseeded with an appropriate mix of native plant species as soon as possible after construction is completed to accelerate the revegetation of these areas and to avoid the establishment and spread of noxious weed species.

• Implementation of a noxious weed control program, in coordination with the Skamania County Noxious Weed Control Board, to control the spread and prevent the introduction of noxious weed species.

3.4.2 FISH

3.4.2.1 Existing Conditions

Lands surrounding the Whistling Ridge Energy Project are generally mountainous with steep-sided narrow drainages. Elevations of the turbine positions range from approximately 2,100 feet to 2,300 feet above msl. The Columbia River flows south of the site and receives runoff via the White Salmon drainage area from the east portion of the site and via the Little White Salmon River from the west portion of the site.

The Whistling Ridge Energy Project is sited on lands characterized by shallow slopes, located between Underwood Mountain and the White Salmon River, approximately three miles from the Columbia River. The proposed layout is situated on a ridge above the Little White Salmon River drainage; however, project elements such as roadway, turbine strings, and facilities do not cross tributaries to this system. The ridgeline is oriented in a north-south direction. A tributary to Little Buck Creek is located in the northeast portion of the project site, and drains into the White Salmon River (Figure 3.4-4). Little Buck Creek is not crossed by any project elements. No perennial streams are located in or adjacent to the Whistling Ridge Energy Project footprint.

Road CG2930 crosses one unnamed, intermittent creek that drains to the south. This road would require small radius improvements to support loads required for construction of the project. West Pit Road crosses one unnamed drainage in the Lapham Creek watershed. This stream had observed flow through the existing culvert under West Pit Road at the time of the July 2009 field visit. However, the surface flow and the channel disappear downstream of the culvert. There is no surface water connection to Lapham Creek and fish are not present in this stream.

Although no special status fish species are present in Little Buck Creek, this creek does drain into Northwestern Lake, which in turn drains into the White Salmon River. The White Salmon River contains evolutionarily significant units and designated critical habitat for three species listed as threatened under the ESA: (1) Lower Columbia River Chinook, (2) Middle Columbia River Steelhead, and (3) Columbia River Chum (Figure 3.4-4).
3.4.2.2 Impacts

Due to the location of water bodies on the project site, no impacts to aquatic species, their habitat, or designated critical habitat are expected as a result of construction and operation of the proposed facility. Water quality would be maintained during construction and operation of the project by incorporating BMPs.

3.4.2.3 Mitigation Measures

Section 3.3, Water, lists the project BMPs that would be incorporated to protect water quality and quantity. Pursuant to an erosion control plan for the project and an NPDES permit, drainage improvements would be made as needed. All temporarily disturbed areas would be regraded and reseeded with an appropriate mix of native plant species to restore vegetation after the construction phase is completed.

3.4.3 WILDLIFE

3.4.3.1 Existing Conditions

Whistling Ridge Energy Project Site

This section summarizes baseline wildlife surveys conducted at the Whistling Ridge Energy Project site discusses potential impacts that may result from the proposed actions, and lists potential mitigation for these impacts.

While the information provided in this section reflects survey efforts comparable to other wind energy facilities permitted in the Northwest, evaluation of wildlife resources within the project site is ongoing. Data presented in this Application were collected during preliminary wildlife and avian surveys. In order to provide the best information available to the decision-making process, the applicant believes that additional data is warranted. Final impact assessments would be conducted during the SEPA process.

The applicant contracted Turnstone Environmental Consultants (TECI), and Western Ecosystems Technology (WEST) to conduct wildlife investigations on the project site. Wildlife surveys were conducted between 2004 and 2008, and included:

- Surveys for northern spotted owl, western gray squirrel, and northern goshawk (TECI)
- Fall avian migration and summer avian breeding/nesting surveys (WEST)
- Bat acoustic surveys (WEST)

In addition, WEST performed avian surveys as part of an analysis of potential avian/wind plant interactions in Klickitat County contained in the Klickitat County Energy Overlay Draft EIS (Kennedy Jenks 2003) and Final EIS (Anchor Environmental 2004). The surveys included two
observation points in Skamania County, in the vicinity of the project site, shown on Figure 1, Avian Survey Points and Geographic Regions Used for Data Analysis, in the Draft EIS.

Current habitat conditions are described in Section 3.4.1 Habitat and Vegetation, and are not repeated below. For complete reports on surveys discussed below, see Appendices B-1 and B-2.

**Special Status Species**

Three special-status wildlife species are documented present within the vicinity of the proposed project: northern spotted owl (*Strix occidentalis caurina*), western gray squirrel (*Sciurus griseus*), and northern goshawk (*Accipiter gentilis*) (Table 3.4-5).

**Northern Spotted Owl.** The northern spotted owl is listed threatened under the ESA. This species also is included as a state-listed threatened species in State of Washington. In Washington State, northern spotted owls inhabit the Eastern and Western Cascades, Western Lowlands and Olympic Peninsula Provinces. Within these regions, the northern spotted owl is associated with a variety of areas containing suitable habitat for nesting, roosting, foraging and dispersal. The species prefers forest habitats characterized by multi-layered canopy, and a high incidence of large trees that provide suitable structure for nesting and roosting. Northern spotted owls have large home ranges and use large tracts of land containing late successional forests. Fragmented forest habitats may be used for dispersal and foraging. Spotted owls will nest in stick nests of northern goshawks, on clumps of mistletoe, in large tree cavities, on broken tops of large trees, or on large branches or cavities in banks and rock faces.

Two historical northern spotted owl activity centers, Mill Creek (MSNO# 0991) and Moss Creek (MSNO#1003), are located north of the project site. The nest cores of both activity centers are located on public lands managed by the WDNR and the US Forest Service (USFS). The Mill creek activity center is composed of contiguous yet scattered northern spotted owl habitat located on private and public (WDNR) lands. This site was designated in 1992, and was last known to have spotted owls present in 2000. Surveys performed since 2000 have not resulted in any spotted owl sightings. The Moss Creek activity center is comprised of patchily distributed northern spotted owl habitat and a mix of rural residential lands, industrial timberland, and lands administered by WDNR and USFS. This activity center was established in 1994 and was last considered to have spotted owls present in 2002. Typically spotted owl activity centers will have their status changed to “historic” after three consecutive years with no documented spotted owl observations. However, the state of Washington currently has a moratorium on changing the status of a known spotted owl activity center. Northern spotted owl critical habitat is designated on lands located to the west/ northwest of the project site, and is almost entirely within the Gifford Pinchot National Forest Boundary. No spotted owl critical habitat is present on the project site.
Spotted owl surveys followed the 1992 Revised Version of “Protocol for Surveying Proposed Management Activities That May Impact Northern Spotted Owls” (USFWS 1992). Surveys were conducted in suitable habitat located in and adjacent to the proposed project site, and included Mill Creek and Moss Creek spotted owl activity centers (Figure 3.4-5).

Suitable habitat was identified using topographic maps, aerial photography, and stand classification data from S.D.S Co., LLC.

During the 2003–2004 survey periods, the project site was surveyed between March 24, 2003 and July 23, 2003 using the one-year survey methodology, and between March 31, 2004 and August 18, 2004 using the two-year survey methodology. An additional survey was completed by TECI in 2004 in order to lengthen the time period in which management activities could occur before surveys would again be required. No spotted owls were detected during the 2003–2004 surveys.

Detailed methodology and results for the 2003 and 2004 northern spotted owl surveys can be found in Appendix B-3.

More recent spotted owl surveys were conducted in May 2008 and spring-summer of 2009. Surveys were conducted using the two-year survey methodology, which requires a minimum of three visits for two consecutive years in order to determine presence/absence of the spotted owl. During the three 2008 surveys, only barred owls were detected. USFWS is developing a new survey protocol addressing interactions between barred owls and spotted owls. The protocol is not due to be available until 2010, however Turnstone was able to obtain suggestions on new survey techniques to be used. One of those suggestions was to visit core areas in the day time looking for spotted owls that may not respond in the presence of barred owls. Turnstone has taken these suggestions and used them in the field, conducting four day site visits up and above the current protocol parameters. Turnstone has completed all required night visits and performed the last day visit on August 10th, all in the core areas where spotted owls were found historically. There have been no visuals or responses to date. Surveys were implemented in all potentially suitable habitat located within a 1.8 mile radius of the corridor (Figure 3.4-5). This area totaled 14,901 acres. The survey area also included the Moss Creek and Mill Creek activity centers, which expanded the survey area by 7,222 acres. No spotted owls were detected in either the survey area or historic activity centers. Detailed methodology and results for the 2008 northern spotted owl surveys can be found in Appendix B-4. The 2009 survey data will be included as part of the EIS.
Western Gray Squirrel. The western gray squirrel is listed as a “threatened” species by the WDFW. In Washington, western gray squirrel distribution has been reduced to three geographically isolated populations: the “Puget Trough” population, centered in Thurston and Pierce counties, the “South Cascades” population, located in eastern Skamania County and Klickitat and Yakima Counties, and the “North Cascades” population, located in Chelan and Okanogan Counties. Western gray squirrels are arboreal species. Although they forage on the ground, this species rarely strays far from trees. They use tree canopies for cover and nesting. Western gray squirrels prefer areas where contiguous tree canopy allows arboreal travel in a minimum of a 198 feet (60 meters) radius around the nest (Ryan and Carey 1995). Western gray squirrels are diurnal species, with most activity occurring during morning hours. This species is most active during August and September, when this species is collecting and storing food for winter (Ryan and Carey 1995). The principal food source for the gray squirrel is acorns; however, conifer seeds are also eaten (Dalquest 1948). While pine nuts and acorns are considered essential foods for accumulating body fat in preparation for winter, green vegetation, seeds, nuts, fleshy fruits, and mushrooms also are consumed (WDW 1993, Carraway and Verts 1994, Ryan and Carey 1995).

Western gray squirrel surveys were implemented by TECI on lands located in and adjacent to the project site in 2004 and 2008 (Figure 3.4-6). Surveys conducted in 2004 included a general search for western gray squirrels and nests while conducting northern goshawk station placement and surveys. Two adult western gray squirrels were identified through that effort.

An additional protocol survey was completed following methods described in “Surveys for western gray squirrel nests on sites harvested under approved forest practice guidelines: analysis of nest use and operator compliance” (Van der Haegen, Van Leuven, and Anderson 2004). No western gray squirrels were detected during protocol surveys. Detailed methodology and results for western gray squirrel surveys can be found in Appendix B-3.

Additional western gray squirrel surveys were completed by TECI in 2008. Prior to implementing field surveys, TECI consulted with a WDFW biologist to identify survey criteria and methodology. It was determined that gray squirrels surveys should be performed in areas where project activities would result in the removal of potential western gray squirrel habitat or structural modification (i.e., stand thinning), and these surveys should include unaltered habitat within 400 feet of potential disturbance.

An area consisting of a 1,050-foot buffer around the proposed turbine layout to account for lands that may be impacted by the project, and also the 400-foot buffer of undisturbed lands, was identified for potential survey. This area included 1,420 acres; however, only 738 acres was identified as potentially suitable to support western gray squirrel (Figure 3.4-6). Surveys were conducted following methods described by Van der Haegen, Van Leuven, and Anderson (2004). Surveyors searched for individuals and nests, focusing mainly on gray squirrels, but also noting other species. When possible, historical use by western gray squirrels was determined. No gray squirrels or nests were detected during these surveys. Detailed methodology and results can be found in Appendix B-4.
Northern Goshawk. The northern goshawk is categorized as a “species of concern” by the U.S. FWS, and as a “listing candidate” for sensitive, threatened or endangered species by the State of Washington. Goshawks inhabit a wide variety of forest habitats, including true fir (red fir, white fir, and subalpine fir), mixed conifer, lodgepole pine, ponderosa pine, Jeffrey pine, montane riparian deciduous forest and Douglas fir. They are occasionally found nesting in coast redwood and mixed hardwood forest. Goshawk nest sites tend to be associated with patches of relatively large, dense forest; however, home ranges often consist of a wide range of forest age classes and conditions. Nest sites tend to be positively correlated with proximity to water or meadow habitat, forest openings, level terrain or “benches,” northerly aspects and patches of larger, denser trees, although variation in habitat associations does occur (USFWS 2002).

Northern goshawk surveys were conducted by TECI biologists in 2003 and 2008 on properties managed by S.D.S. Co., LLC and adjacent private land. In 2003, surveys were conducted in suitable habitat located in four core project sections, including the provincial home range radius of 0.5 mile around the core area (Figure 3.4-6). Suitable habitat was identified using topographic maps and aerial photography. Survey stations were establish at 0.2-mile intervals on roads and trails located in suitable habitat within 0.5 mile of a proposed wind turbine location. Potential goshawk habitat was surveyed in accordance with “Survey Methodology for Northern Goshawks in the Pacific Southwest Region” (Woodbridge and Hargis 2006). All raptor species responses detected during surveys also were recorded.

TECI completed two protocol surveys during the 2004 northern goshawk survey season. One hundred eighty five calling stations were surveyed each time. No northern goshawk responses were recorded during any of the two site visits. Detailed methodology and results for northern goshawk surveys can be found in Appendix B-3.

In 2008, the potential survey area for the northern goshawk was determined by protocol parameters outlined in the Northern Goshawk Inventory and Monitoring Technical Guide (USFS 2006), consultation with biologists from the WDFW and GIS analysis. The survey area was established by placing a 150-foot buffer around the turbine string layout, and then adding an additional 2,624 foot buffer per protocol. Forest stands with greatest potential to contain suitable habitat structure and composition to support northern goshawk were identified using GIS data and aerial photographs. Criteria for selecting stands included stand age greater than 25 years, and an average tree dbh of at least 12 inches. Based on these criteria, 1,093 acres was identified for surveys (Figure 3.4-6).

It was determined that the “Broadcast Acoustical Survey” methodology would be used for a two-year survey effort. TECI biologists completed two protocol surveys at 136 calling stations during the 2008 goshawk survey season. The first survey was conducted during the nesting period, and the second during the fledgling period. No northern goshawk responses were documented during either of the two site visits. Detailed methodology and results can be found in Appendix B-4.

Summary of Survey History. The project layout was finalized in October 2008, and included additions to proposed turbine strings, removal of previously proposed turbines, and identification
of areas requiring improved roadways. Changes to the project layout resulted in lands added to the project area that, in some cases, were not included in wildlife surveys conducted prior to October 2008. The effect of these changes regarding special status species are:

- For northern spotted owls, the final turbine alignment did expand the area requiring owl surveys; however, because the survey area had included spotted owl activity centers located at the northern reach of the project site, the area was accounted for in the May 2008 surveys.

- For western gray squirrels, the final turbine alignment did expand the area requiring western gray squirrel surveys. These areas were identified after surveys were completed; however, the survey window was still open and an additional field survey was implemented in added areas.

- The applicant completed northern goshawk surveys in accordance with protocols accepted and recommended by WDFW. The surveys were conducted during the relevant seasons in 2004, 2005, 2008 and again in 2009. No goshawks were found on the project site, nor were any observed on any surrounding properties. It is highly unlikely that goshawks will be found on the project site or in areas to the north, owned and managed by WDNR. The applicant would conduct an additional survey on the project site in spring 2009 to confirm these findings, in accordance with agreed protocols. The WDNR property near the project site has similar habitat characteristics to the project site, and was recently logged. While no goshawks are expected on the area to the north, due to the proximity of turbines to the WDNR property to the north, the Applicant would conduct an intensive survey effort on approximately 360 acres to the north of the project site to confirm that the project does not present any significant impact to this species.

- Anabat detection surveys proposed for 2009 would have been implemented during the months of July through October, and would augment our understanding of bat activity within the vicinity of the proposed micrositing corridors. Anabat detectors have also been elevated to gain a better understanding of bat activity at rotor swept height.

**Avian Migration and Breeding/Nesting Surveys**

Avian surveys were conducted during the fall migration period (September 11 to November 4, 2004) and the breeding/nesting season (May 15 to July 14, 2006) by WEST biologists. Study protocol followed methods described by Reynolds et al. (1980). An 800-meter circular plot was centered on each observation point (Figures 3.4-7 and 3.4-8). All observations, behavior, and flight patterns of birds in and near plots were recorded. Flight patterns, such as direction of travel and flight altitude also were recorded. Observations of birds beyond the 800-meter radius were recorded; however, these data were analyzed separately from data collected from survey plots. The location of raptors, other large birds, or species of concern observed during counts was recorded on field map.

Skamania County, Washington
A relative index to collision risk \((R)\) was calculated for bird species observed in the survey area using the following formula:

\[ R = A \times P_f \times P_t \]

Where \(A\) = mean use for species \(i\) averaged across all surveys, \(P_f\) = proportion of all observations of species \(i\) where activity was recorded as flying (an index to the approximate percentage of time species \(i\) spends flying during the daylight period), and \(P_t\) = proportion of all flight height observations of species \(i\) within the rotor-swept height.

This index does not account for differences in behavior other than flight characteristics (i.e., flight height and proportion of time spent flying). Point count data were used to establish diurnal indices of avian use, and how these indices compare to other wind resource areas in the United States.

**Fall Migration Surveys (2004).** General avian surveys identified thirty-nine 39 species of bird in the survey area (Figure 3.4-8). Passerines (songbirds) were the most abundant avian group, constituting 87.4% of observations. This group was also observed with the greatest frequency (94.4% of surveys). Raptors were the second most abundant group observed; however, this group represented only 4.9% of observations. Raptors were observed during 38.5% of the surveys, followed by woodpeckers (22.6% of surveys) and doves/pigeons (9.3% of surveys).

The most common species at the project site included dark-eyed junco, American goldfinch, Steller’s jay, common raven, and white-crowned sparrow. The species of birds most frequently observed during fall surveys were common raven, Steller’s jay, dark-eyed junco, red-breasted nuthatch, and golden-crowned kinglet. Eight species of raptor were observed during the survey. Those with the highest use of the site were sharp-shinned hawk, Cooper’s hawk, and red-tailed hawk. The highest raptor use observed at the site during 2004 surveys occurred between September 11 and October 12, 2004. These data do not indicate that any areas within the proposed site have substantially higher raptor use than others.

No federal or state listed endangered or threatened avian species were observed during the survey period. Four state candidate species were observed: golden eagle, northern goshawk, pileated woodpecker, and Vaux’s swift. Two State Monitor species were also observed, including four single turkey vultures and four groups totaling 27 western bluebirds. Detailed results and summary tables can be found in Appendix B-5.

**Summer Breeding Nesting Surveys (2006).** Fifty-five species of birds were observed during summer breeding and nesting surveys in 2006. Passerines were the most abundant group (88.5%), followed by raptors and woodpeckers (3.3% each), and doves/pigeons (3.2%). The most frequently observed groups were passerines (100% of surveys), woodpeckers (35.6% of surveys), and raptors (31.1% of surveys). Species with the highest use of the project site included white-crowned sparrow, red crossbill, western tanager, spotted towhee, and MacGillivray’s warbler. The most frequently observed species included white-crowned sparrow (77.8% of the surveys), western tanager (75.6% of surveys), spotted towhee (64.4% of surveys), MacGillivray’s warbler (48.9%), and dark-eyed junco (48.9%). Three species of raptors were
observed, including red-tailed hawk, northern goshawk, and sharp-shinned hawk. Raptor use in the fall was only slightly higher than during the summer breeding season. The data do not indicate that any portions of the project site have substantially higher raptor use than other areas. For all bird species combined, use of the project site by avian species was slightly higher during the summer breeding season than during the fall migration period.

Detailed results and summary tables can be found in Appendix B-6.

**Bats**

This section describes the results of bat acoustic studies conducted for the Whistling Ridge Energy Project in 2007 and 2008. Detailed information on these investigations can be found in Appendices B-7 and B-8.

Bat acoustic studies conducted in 2007 and 2008 were implemented at various locations on the project site. The purpose of these surveys was to quantify bat use of this area, and use these data to estimate the seasonal and spatial use of the project site. Passive Anabat® II echolocation detectors coupled with Zero Crossing Analysis Interface Modules (ZCAIM; Titly Electronics Pty Ltd., NSW, Australia) were used in both survey years. Anabat detectors record bat echolocation calls using a broadband microphone. Bat species are generally grouped into those that emit low frequency (<35 kHz) or high frequency (≥ 35 kHz) calls. The units of activity equaled the number of bat passes, and were used to calculate the number of bat passes per detector night (Hayes 1997). The data thus indicate the level of bat activity rather than absolute abundance.

In 2007, detectors were placed at two locations from August 20 through October 21 (Figure 3.4-9). The northernmost detector was located just outside the proposed corridor. This detector was initially placed at ground level; however, it was raised to a height of 130 feet (40 meters) on September 7. The southernmost detector was located outside the project site (i.e., outside of the Township, Range, and Section described above); however, it was placed in habitat believed to be representative of that found on the project site. The southernmost detector was placed at ground level, and remained at that location for the duration of the study.

Due to equipment failures, both Anabat detectors were only operable for 24% of the sampling period, amounting to 45 detector-nights. During this survey period, 348 bat passes were recorded. Bat activity was similar between north and south ground level Anabat units (mean = 11.67 ± 2.0 and 9.6 ± 4.1, respectively). At both ground-level locations, the number of high-frequency bat passes per detector night was approximately one and a half times greater than the number of low-frequency passes. High frequency calls are associated with species such as western red bat and mouse-eared bats (Myotis spp). Bat activity recorded after the northern Anabat detector was elevated was much lower (mean = 2.47 ± 1.1) than that recorded at ground level, and passes of low-frequency bats greatly outnumbered high-frequency bat passes. Low-frequency calls are associated with big brown bat, silver-haired bat, and hoary bat. Conclusive species identification was only possible for hoary bat, which accounted for approximately 5% of all species.
Revised Figure 3.4-9
Location of Bat Acoustic Studies

Source: GeoDataScape.
Job No. 33758687

Whistling Ridge Energy Project
Skamania County, Washington
Patterns of nightly activity were similar among detector locations; however, definitive comparisons cannot be made because the timing of when the north detector was placed at ground-level did not coincide with when data was collected from the southern ground-level detector.

The bat acoustic survey effort was greater during the 2008 survey period. Four Anabat detectors were placed in the project vicinity from July 3 to October 7, 2008 (Figure 3.4-9). This period corresponded with summer breeding and fall bat migration. One detector was placed at a wetland located to the west of turbines C1–C4. Data collected at this site are used to assess activity levels of local breeding bats that may be using the wetland, but was not used to evaluate risk of bats to collision mortality. The remaining three detectors were placed in upland habitats that more closely resembled habitat where turbines may be placed (one in a linear road corridor that passed through forested habitat, and two others in clearcuts).

For the three upland survey locations, bat activity was monitored for a total of 97 nights. Anabat detectors were operational for 95.5% of the sampling period. A total of 39,326 bat passes were recorded during 278 detector-nights. Average bat passes per detector night at the upland locations equaled 138.44. A total of 80.7% of all bat passes was recorded from the detector located in the road corridor. Bat passes recorded in clearcut habitats accounted for only 19.1% of all bat passes.

Bat activity at the wetland location was monitored for a total of 97 nights, and was operational 100% of the time. A total of 17,269 bat passes were recorded during 97 detector-nights. The average number of bat passes per detector night at this location equaled 178.03.

Temporal activity patterns were similar among the upland survey locations, with the highest bat activity occurring during the months of July and August. Peak activity across all upland sites occurred between July 10 and July 16. Bat activity in the wetland area was highest during the month of July, with peak activity occurring on July 5. Bat activity in this area between July 3 through mid-August was over four times higher than activity from mid-August through October 7 (mean = 218.6/detector night and 52.3/detector night, respectively).

At the upland sites, low-frequency bats accounted for 67% of all bat passes. The opposite was true for the wetland site, where high-frequency bats accounted for 69.7% of all bat passes. As in 2007, species identification was only possible for the hoary bat. Hoary bats comprised 6.0% of passes recorded at upland locations, and use was similar across the three sites. This species comprised 2.0% of total bat passes recorded at the wetland location. Activity was relatively high at the wetland and road corridor stations, and accounted for the majority of the calls recorded. Increased activity near the wetland is likely due to bats drinking and foraging in this area. Increased activity along the linear road clearing is likely due to its use as a travel corridor by local bats.

The 2008 acoustic surveys resulted in a vastly higher detection rate than that observed during 2007 surveys. Several factors contributed to the high level of detected bat activity during the 2008 surveys, including increased number of survey sites and the fact that all detectors were placed at ground level where heightened foraging activity occurs. However, the primary reason...
for the greater number of detections recorded during 2008 surveys were due to timing and locations of the equipment. In 2008, four times the number of bats was recorded from July 3 to mid-August, as mid-August through October; the peak activity period recorded in 2008 was thus missed during 2007 surveys as detectors were not installed until late August.

The temporal variation in activity levels is indicative of the importance of conducting detection surveys during this period. Anabat detection surveys proposed for 2009 would have been implemented during the months of July through October, and would have augmented our understanding of bat activity within the vicinity of the proposed corridor. Anabat detectors have also been elevated to gain a better understanding of bat activity at rotor swept height.

**Priority Wildlife Habitats**

Priority wildlife habitats, including mule deer and black-tailed deer winter range, are present to the east of Underwood Mountain, extending to lands located to the north/northeast. Winter range for Columbia black-tailed deer is present in lands located west of Underwood Mountain, and extends north and south from the project site. Elk winter range is present throughout the project site.

**Improved Roadways outside the Site Boundary**

Access to the Whistling Ridge Energy Project would require traversing lands located within the Columbia River Gorge National Scenic Area using Cook-Underwood Road to Willard Road, and then via a new connection to West Pit Road to the project site boundary. West Pit Road is an existing private logging road. Approximately 4.5 roadway miles in this area would require improvement as a result of the proposed project. This section would be used to connect existing County roads within the Scenic Area to other existing roads owned by S.D.S. Co., LLC.

**3.4.3.2 Impacts**

**Whistling Ridge Energy Project Site**

Construction and operation of the Whistling Ridge Energy Project is expected to have limited impacts on wildlife resources. Project actions would include the construction of permanent roadways, improvement (i.e. widening and resurfacing) of existing roadway, and the installation and operation of wind turbines. Impacts to wildlife habitat may result from vegetation removal in forested areas where the proposed roadway and turbine alignment is planned. Vegetation management in areas surrounding each turbine would range from complete removal of vegetation to limitations on tree height.

Wildlife and avian investigations conducted to date quantify the use of habitats located within the project site. Surveys for federally listed and candidate species, avian migration and breeding, and bat acoustic studies are ongoing, and include northern goshawk and bat surveys planned for 2009. The analysis presented below establishes an analytical framework and data for evaluation of the Application.
**Special Status Species**

Three federally listed or candidate species have the potential to occur within the project site, including northern spotted owl, western gray squirrel, and northern goshawk.

**Northern Spotted Owl.** The spotted owl prefers forest habitats characterized by multi-layered canopy, and a high incidence of large trees that provide suitable structure for nesting and roosting. No late seral forests are present within the project site. It is assumed that active timber harvest that has occurred in this area has altered the landscape such that limited suitable habitat exists. Further, no spotted owls have been detected in the proposed project site or spotted owl activity centers located in proximity to the proposed project. No impacts to northern spotted owls are expected.

**Western Gray Squirrel.** The gray squirrel prefers habitat where contiguous tree canopy allows arboreal travel in a minimum of a 198-foot (60-meter) radius around the nest (Ryan and Carey 1995). Ongoing forest management on lands located within the proposed project site has reduced suitable habitat for this species through fragmentation of mature forest stands. Contiguous forest habitat located on the project site would not persist indefinitely in the absence of the proposed project. The project site also contains very few oak trees, and those that were observed were of small stature (less than 20 feet tall), stunted, and growing in openings on exposed rocky slopes in shallow soils. Acorn crops from oak trees are an important food source for western gray squirrels, and the lack of this primary food source may deter use of the project site by gray squirrels. Because habitat for this species is considered rare or of moderate/poor quality on the project site, impacts to western gray squirrel are expected to be negligible.

**Northern Goshawk.** Goshawks inhabit a wide variety of forest habitats, including true fir, mixed conifer, montane riparian deciduous forest and Douglas fir forests. Goshawk nest sites tend to be associated with patches of relatively large, dense forest located in proximity to water; however, home ranges often consist of a wide range of forest age classes and conditions. Although no goshawks were detected during protocol surveys, individuals were spotted during general avian migration and breeding surveys. Potential impacts to this species may include turbine collision-related mortality or displacement; however, the risk for this species is considered low.

**Avian Species (General)**

**Construction Impacts.** Impacts to avian species are not anticipated during construction of the proposed project. Certain species may be temporarily displaced due to construction related noise and increased traffic volume; however, permanent impacts to these species are not expected.

**Operational Impacts.** Potential operation-related impacts to avian species include turbine collision and displacement. Based on the exposure index derived from abundance and flight behavior, the species most likely to collide with wind turbines located at the project are red crossbills (R = 0.77), Steller’s Jay (R = 0.37), common raven (R = 0.33), American Goldfinch (R = 0.29), and western bluebird (R = 0.22). The highest index for any raptor was 0.08 for red-tailed hawk, indicating a risk approximately 10 times lower than for the red crossbill. A regression analysis using data collected during avian surveys estimated a raptor/vulture fatality
rate of 0.049/MW/year, or 4–5 raptors per 100 MW per year. This fatality estimate is relatively low compared to many wind projects (Appendix B-6). Further, data collected from the project site indicate that the area is not within a major migratory pathway, at least during fall migration.

Based on the two seasons of surveys, overall use of the project site by golden eagle, northern goshawk, pileated woodpecker, prairie falcon, and willow flycatcher was very low. Adverse impacts to these species are not anticipated. Of the species that were commonly observed, turkey vultures have very low susceptibility to turbine collisions (Orloff and Flannery 1992). To date, this species has not been documented as a turbine fatality in the Pacific Northwest. Vaux’s swifts, western bluebirds, and olive-sided flycatchers were commonly observed flying at rotor-swept heights, and some turbine-related mortality may occur for these species over the life of the project. These collisions would likely be rare, and it is unlikely that the Whistling Ridge Energy Project would have any negative impacts on population levels on and near the project site. Higher numbers of Vaux’s swifts and western bluebirds were recorded during fall migration, whereas olive-sided flycatcher appears to primarily use the project site for breeding.

Waterfowl, waterbirds, and shorebirds were not observed using lands within the project site during this study, and mortality involving this group is expected to be rare. Based on abundance, passerines are expected to make up the largest proportion of fatalities at the Whistling Ridge Energy Project. Post-construction mortality data collected at other windfarms in Washington and Oregon indicate that less correlation between pre-construction surveys and turbine-related mortality is observed in non-raptor species. The lack of correlation may be because most fatalities are among nocturnal migrants that are not accounted for during surveys.

The avian use information for the project site is based on detections of birds seen and/or heard calling. Because songbirds are less vocal during fall, this information may be skewed toward summer use. Similarly, the level of night migration for species associated with the project site is also not known. Risk analyses presented above provide some insight into which species are most vulnerable to turbine collision; however, estimates are based on abundance, proportion of daily activity budget spent flying, and flight height of each species. Observations were made during daylight hours, and do not take into consideration flight behavior or abundance of nocturnal migrants. Further, the analysis also does not account for varying ability among species to detect and avoid turbines, habitat selection, or other factors that may influence exposure to turbine collision. As a result, actual risk may be lower or higher than indicated by these estimates (Orloff and Flannery 1992).

In addition to direct mortality through collisions, the presence of wind turbines may alter the landscape, thereby displacing wildlife away from the project facilities. Habitat for avian species may be lost through vegetation clearing for roadways construction and improvement, and in areas surrounding wind turbines. Several studies have reported on this effect and are summarized in Appendix B-6.

**Bats**

**Construction Impacts.** Impacts to bats are not expected during the construction of the proposed project.
Operational Impacts. It is likely that some bat mortality would occur during operation; however, mortality estimates are difficult due to our lack of understanding of why bats collide with wind turbines (Kunz et al. 2007, Baerwald et al. 2008). Several factors may aid in the assessment of potential impacts to bats, including site-specific habitat and topography, species composition, and activity patterns. Investigations of bat use of the project site are ongoing. Ongoing surveys would augment existing data and better define our understanding of spatial and temporal patterns of bat use of the project site. A preliminary assessment of potential impacts to bats that may result from construction or operation of the Whistling Ridge Energy Project is provided below. This assessment was completed by examining site-specific habitat features and bat acoustic data collected to date. Additional insight from investigations conducted at other wind farms is presented where relevant.

Turbine-related mortality to bats on the project site may be lower than expected based on observed bat activity levels. The majority of detected species were high-frequency species, most of which were likely from the genera *Myotis*. This genus has among the lowest recorded mortality rates at wind resource areas throughout the US, comprising only 0–13.5% of the fatalities (Arnett et al. 2008). At existing wind-energy facilities in eastern Oregon and Washington, approximately 96% of all recorded fatalities were low-frequency species. These data indicate that high-frequency species, such as *Myotis* bats, are much less susceptible to turbine collisions than low-frequency species. Ongoing studies would help to better understand whether more susceptible low-frequency species have been underestimated in surveys conducted to date.

The timing of peak bat activity on the proposed project site (July to mid-August) does not coincide with when the highest levels of bat mortality have been documented at other wind farms in the US. Fatality studies have shown a peak in mortality in August and September and generally lower mortality earlier in the summer (Johnson 2005, Arnett et al. 2008). While the survey effort varies among the different studies, the studies that combine Anabat surveys and fatality surveys show a general association between the timing of increased bat call rates and timing of mortality, with both call rates and mortality peaking during the fall (Kunz et al. 2007). The highest use of the project site occurred in July and early August, prior to the time that most bat mortality occurs at wind resource areas in the Pacific Northwest as well as throughout the US.

High bat activity in July and early August is likely due to use of the project site by local bats during the reproductive season, when pups are being weaned and foraging rates are high. Activity beyond mid-August likely represents movement of migrating bats through the area. Activity by hoary bats also was substantially higher in July, and dropped off significantly beginning in early August. After August 31, activity for all bats was very low relative to earlier dates, indicating that most bats had left the area for winter hibernacula or warmer climates. These data indicate higher use of the project site by resident populations of bats, rather than by migrants passing through the area. Further, high bat activity levels during the breeding season, as seen on the project site, do not equate to high bat fatality rates. Low mortality has been documented during the breeding season at several wind farms, even when relatively large bat populations were present in the area (Fiedler 2004, Gruver 2002, Howe et al. 2002, Johnson et al. 2004, Schmidt et al. 2003).
Finally, no known large bat colonies are present near the proposed Whistling Ridge Energy Facility. The nearest known hibernaculum is located near the town of Trout Lake, nearly 20 miles north of the proposed project (B. Weiler, personal communication). The project site does not contain topographic features, such as canyons, that may funnel migrating bats toward corridors where turbines would be placed. No turbines would be constructed near wetlands or ponds, and cleared areas surrounding turbine strings would closely mimic clearcuts, where to date, recorded bat activity levels on the project site were the lowest.

Based on data collected to date on species composition, activity patterns and habitat use, significant adverse impacts to bats are not anticipated as a result of the proposed project. Data collected during 2009 surveys would improve our understanding of bat use and activity patterns, and help to refine our assessment of the degree of impacts and potential mitigation measures, if any.

**Priority Wildlife Habitats**

**Construction Impacts.** Mule deer, black-tailed deer, and elk may be displaced temporarily from winter range if the timing of construction activities coincides with use of these habitats. Construction-related displacement is expected to be of short duration.

**Operational Impacts.** Because data on impacts to big game as a result of wind farm operation is limited, it is difficult to predict the impact of the proposed project on wildlife using priority habitats on the proposed project site. Additional coordination with WDFW is ongoing, and would continue to address this resource.

**Improved Roadways outside the Site Boundary**

A total of 2.4 roadway miles located outside the proposed project site would require upgrades as a result of the proposed project. These roads, West Pit Road, would traverse forests of varying stand age. Half of upgraded roads are adjacent to areas characterized by recent clearcut harvest. Based on minimal habitat loss as a result of roadway construction and improvement, impacts to wildlife are expected to be minimal.

Temporary impacts to wildlife may occur as a result of construction-related traffic and noise. These impacts would terminate after the project is constructed, and traffic levels similar to that currently observed would resume.

**3.4.3.3 Mitigation Measures**

The primary mitigation goal for the Whistling Ridge Energy facility is to avoid sensitive wildlife resources when siting turbines and access roads. Because of the relatively small footprint of wind energy facilities and the flexibility of the process, it is likely that avoidance can be achieved. Wind turbines would also be sited in areas already actively managed for timber harvest. New road construction would be minimized by improving and using existing roadways.

All temporarily disturbed areas would be regraded and reseeded with an appropriate mix of native plant species to restore vegetation after the construction phase is over.
Mitigation for potential impacts resulting for the proposed project includes the following sequentially-performed actions:

- Rectify the impact by repairing, rehabilitating, or restoring the affected environment in consultation with relevant wildlife agencies.

- Conduct thorough analysis of sensitive natural resources to avoid impacts and increase avoidance during micrositing.

- Implement a two year minimum post-construction mortality study

- The Applicant plans to convene a Technical Advisory Committee to evaluate the mitigation and monitoring program and determine the need for further studies or mitigation measures. The Technical Advisory Committee would be composed of representatives from WDFW, USFWS, Skamania County, and the Applicant. The role of the Technical Advisory Committee would be to coordinate appropriate mitigation measures, monitor impacts to wildlife and habitat, and address issues that arise regarding wildlife impacts during construction and operation of the project. The post-construction monitoring plan would be developed in coordination with the Technical Advisory Committee.

- Implement project design features that would minimize project impacts, including:
  - Installing tubular steel turbine towers to eliminate perching opportunities provided by lattice towers
  - Burying electrical lines between turbines and from turbine strings to substation
  - Using the minimum amount of turbine lighting required by the FAA
  - Installing newer generation up-wind turbines
SECTION 3.5 WETLANDS AND OTHER JURISDICTIONAL WATERS
(WAC 463-60-333)

3.5.1 EXISTING CONDITIONS

A wetland investigation was performed at the project site and along roads proposed to be
upgraded for the project on October 26, 2006 and January 9, 2007 (CH2M Hill 2007) (Appendix
C). Since the time of those surveys, a new site access route has been identified between SR 14
and the project site to be used for equipment delivery and construction and operation labor.
Additional wetland field work was completed in spring 2009 along the roadways proposed for construction access and confirmed that no additional wetland areas are present that would be affected by construction or operation of the project.

3.5.1.1 Project Site

No wetlands or wetland indicators were identified within the study area (the turbine corridors
and originally proposed access roadways). One undelineated wetland is identified to occur
outside the study area perimeter west of turbines C1-C4 (Figure 3.5-1, Project Site Wetlands). This wetland is labeled as “Cedar Swamp” on the USGS map and is listed as palustrine
unconsolidated bottom, semipermanently flooded, impounded (PUBFh) on the National Wetland
Inventory (CH2M Hill 2007). The Cedar Swamp wetland buffer does not extend into the study
area.

Five intermittent drainage ways that provide short duration runoff during storm events or spring
snowmelt meet the Skamania County Critical Areas criteria for Class V Streams (CH2M Hill
2007). The drainage ways do not contain channels, scour marks, or other characteristics that
meet the definition of waters of the US or Washington state. The planned improvements to
existing roads that would occur inside the Scenic Area would cross one intermittent stream
(shown on Figure 3.3-1). See Section 3.3 for a discussion of surface water.

3.5.1.2 Improved Construction Access Roadways

A preliminary review of the National Wetland Inventory indicates wetlands occur along SR 14
near White Salmon, Washington (Figures 3.5-2a and 3.5-2b, Access Route NWI Wetlands). As
described in Section 4.3 Transportation, very minor intersection improvements to SR 14
would be required but no wetland impacts are anticipated to occur. The National Wetland
Inventory does not show the presence of wetlands along the local secondary and forest roads
proposed to be used by the project. As the National Wetland Inventory is based on historic aerial
photography interpretations, a field investigation was conducted in July 2009 to confirm whether or not that wetlands and other regulated waters of the US or the State
may or may not be impacted by the project.

1 The wetland on the project site results from a constructed impoundment according to National Wetland Inventory
maps and so is not regulated locally as a critical area according to SCC Title 21A.04.020(A)(1)(b).

Job No. 33758687

Whistling Ridge Energy Project
Skamania County, Washington
3.5.2 IMPACTS

3.5.2.1 Project Site

No wetlands or wetland buffers are located within the project construction or operation area. Therefore, no wetlands or buffers are expected to be impacted by construction or operation of the project.

3.5.2.2 Improved Construction Access Roadways

A review of the National Wetland Inventory indicates that wetlands may occur along SR 14 but not along County or private roads proposed for the project’s construction access and turbine delivery routes. **No** intersection improvements to SR 14 are anticipated to be required, and with no wetland-related impacts **would occur**. Roadway improvements to the County or private logging roads are not expected to permanently impact wetlands or waters of the US or State. This information was confirmed through field investigations planned for spring, performed in July 2009.

3.5.3 MITIGATION MEASURES

No impacts to wetlands are expected to occur and therefore no mitigation measures would be required.
SECTION 3.6 ENERGY AND NATURAL RESOURCES
(WAC 463-60-342)

3.6.1 INTRODUCTION

The Whistling Ridge Energy Project would consume limited amounts of energy and natural resources, primarily during construction. Operation of the project would consume very limited amounts of natural resources, as the wind turbine generators would use wind, an abundant, naturally occurring renewable resource, to generate electricity. By using wind to generate electricity, operation of the project would help reduce overall consumption of non-renewable natural resources.

Wind farms have a very high “energy payback” (ratio of energy produced compared to energy expended in construction and operation), and wind’s energy payback time is one of the shortest of any electrical generation technology. It takes approximately three to eight months, depending on the wind speed at the site, for a wind farm to produce the total amount of energy used to construct the equipment and build the project. (AWEA 2008).

3.6.2 ENERGY REQUIRED

3.6.2.1 Construction

Types and quantities of energy and natural resources consumed during construction are as follows:

- 19,250 gallons of fuel (diesel and gasoline) for construction equipment
- 3,700 tons of steel for turbine towers
- 1,000 tons of steel for tower foundation reinforcement
- 100,000 yards of gravel (aggregate) for roads and crane pads
- 10,000 cubic yards of concrete for turbine foundations
- 1.7 million gallons of water for road compaction, dust control, wetting concrete, etc., assuming plain water is used for dust control (this amount could be reduced through the use of lignin or other dust palliative if permitted by EFSEC)

3.6.2.2 Operation of Facility

Operation of the project would consume limited amounts of energy and non-renewable natural resources. During operations, electrical energy would be consumed on a limited basis during times when the wind generated on site is insufficient to power FAA lights and security lights at the Operations and Maintenance and substation facilities. In addition, turbines require electrical energy to run lubrication pumps and cooling systems, electrical monitoring systems, and positioning motors even when wind speeds are below generation levels. Energy would be
generated using wind transformed into electricity by turbine generators. Types and quantities of energy and natural resources consumed during operations are as follows:

- Fuel for Operation and Maintenance vehicles (approximately 8,500 gallons annually)
- Minor quantities of lubricating oils, greases and hydraulic fluids for the wind turbine generators
- Electricity for project operations (less than approximately 600 kilowatt hours per wind turbine generator per month)
- Water for use at the Operations and Maintenance facility and periodic maintenance of turbine blades (less than approximately 5,000 gpd)

3.6.3 SOURCE AND AVAILABILITY OF ENERGY AND NATURAL RESOURCES

3.6.3.1 Sources during Construction

The source of fuel for construction equipment and vehicles would be licensed fuel distributors or gas stations, as described in Section 2.9, Spill Prevention. Water for construction would be obtained from a local source, as described in Section 3.3, Water Resources. Concrete would be purchased from existing suppliers located near the project site. Electricity for construction equipment would be provided from portable generators.

3.6.3.2 Sources during Operation

Fuel used for Operation and Maintenance vehicles would be purchased from local gas stations. Lubricating oils and hydraulic fluids used for wind turbine generator maintenance would be purchased from distributors. Electricity for project operations would mostly be generated by the project itself; during periods when the wind turbines are not generating power, it would be purchased from the Skamania County Public Utility District #1.

3.6.3.3 Materials and Commodities

As described in Subsection 3.6.1, bulk materials such as aggregate gravel and sand, in addition to soils, would not be required. Any additional material would be supplied locally from existing quarries. Other building materials, equipment, and other operational commodities would be purchased from equipment and material suppliers.

3.6.4 NONRENEWABLE RESOURCES

While a wide variety of natural resources are used in the construction of a project such as the Whistling Ridge Energy Project, the amounts of most resources used are very small. The largest quantities would be steel (coming from iron ore) and concrete (coming from aggregate, sand, and cement quarries and pits). Diesel fuel and electricity also would be consumed during construction.
3.6.5 CONSERVATION AND RENEWABLE RESOURCES

The project would provide the region with low-cost, clean, renewable energy, in accordance with state and national policies and priorities. It would provide benefits because it would emit substantially lower quantities of air pollutants per unit of energy output compared to other forms of energy. The project would help maintain air quality, given that some new generation resources must be developed to meet growing energy demand and to replace generation that will be retired.

3.6.6 SCENIC RESOURCES

The project is not located inside the Columbia River Gorge National Scenic Area; however, the proposed access road for the proposed site, West Pit Road, is. Conformance with the Scenic Area plan for roadway development would be followed as described in Section 2.20, Pertinent Federal, State and Local Requirements and in Section 4.2.1, Land Use.

State Highway 14 in this area is a recognized scenic roadway. Typically, this designation means that a scenic corridor management plan would be prepared to provide policy-level guidance in the local adoption of comprehensive plan policies, zoning, and other land use regulation. There is no scenic corridor management plan for Highway 14 and, therefore, no regulatory control of aesthetic impacts within the corridor.

3.6.7 MITIGATION MEASURES

No impacts to energy and natural resources are expected to occur and therefore no mitigation measures would be required.
SECTION 4.1 ENVIRONMENTAL HEALTH  
(WAC 463-60-352)

This section contains six subsections: Noise, Risk of Fire or Explosion, Releases or Potential Releases to the Environment Affecting Public Health, Safety Standards Compliance, Radiation Levels, and Emergency Plans.

4.1.1 NOISE

4.1.1.1 Fundamentals of Acoustics

Noise is generally defined as loud, unpleasant, unexpected, or undesired sound that is typically associated with human activity and that interferes with or disrupts normal activities. Although exposure to high noise levels has been demonstrated to cause hearing loss, the principal human response to environmental noise is annoyance. The response of individuals to similar noise events is diverse and influenced by the type of noise, the perceived importance of the noise and its appropriateness in the setting, the time of day and the type of activity during which the noise occurs, and the sensitivity of the individual.

Sound is a physical phenomenon consisting of minute vibrations that travel through a medium, such as air, and are sensed by the human ear. Sound is generally characterized by several variables, including frequency and intensity. Frequency describes the pitch of the sound and is measured in hertz (Hz), while intensity describes the sound’s loudness and is measured in decibels (dB). Decibels are measured using a logarithmic scale. A sound level of 0 dB is approximately the threshold of human hearing and is barely audible under extremely quiet listening conditions. Normal speech has a sound level of approximately 60 dB. Sound levels above approximately 110 dB begin to be felt inside the human ear as discomfort and eventually pain at 120 dB and higher levels. The minimum change in the sound level of individual events that an average human ear can detect is about 1 to 2 dB. A 3 to 5 dB change is readily perceived. A change in sound level of about 10 dB is usually perceived by the average person as a doubling (or if minus 10 dB, halving) of the sound’s loudness.

Due to the logarithmic nature of the decibel unit, sound levels cannot be added or subtracted directly and are somewhat cumbersome to handle mathematically; however, some simple rules are useful in dealing with sound levels. First, if a sound’s intensity is doubled, the sound level increases by 3 dB, regardless of the initial sound level. For example: 60 dB + 60 dB = 63 dB, and 80 dB + 80 dB = 83 dB.

Sound level is usually expressed by reference to a known standard. This report refers to sound pressure level. In expressing sound pressure on a logarithmic scale, the sound pressure is compared to a reference value of 20 micropascals (µPa). Sound pressure level depends not only on the power of the source, but also on the distance from the source and on the acoustic characteristics of the space surrounding the source.

Hz is a measure of how many times each second the crest of a sound pressure wave passes a fixed point. For example, when a drummer beats a drum, the skin of the drum vibrates a number
of times per second. When the drum skin vibrates 100 times per second it generates a sound pressure wave that is oscillating at 100 Hz, and this pressure oscillation is perceived by the ear/brain as a tonal pitch of 100 Hz. Sound frequencies between 20 and 20,000 Hz are within the range of sensitivity of the best human ear.

Sound from a tuning fork contains a single frequency (a pure tone), but most sounds one hears in the environment do not consist of a single frequency but rather a broad band of frequencies differing in sound level. The method commonly used to quantify environmental sounds consists of evaluating all frequencies of a sound according to a weighting system that reflects that human hearing is less sensitive at low frequencies and extremely high frequencies than at the mid-range frequencies. This is called “A weighting,” and the decibel level measured is called the A-weighted sound level (dBA). In practice, the level of a noise source is conveniently measured using a sound level meter that includes a filter corresponding to the dBA curve.

Although the dBA may adequately indicate the level of environmental noise at any instant in time, community noise levels vary continuously. Most environmental noise includes a mixture of noise from distant sources that creates a relatively steady background noise in which no particular source is identifiable. A single descriptor called the equivalent sound level (L\text{eq}) may be used to describe sound that is changing in level. L\text{eq} is the energy-mean dBA during a measured time interval. It is the “equivalent” constant sound level that would have to be produced by a given source to equal the acoustic energy contained in the fluctuating sound level measured. In addition to the energy-average level, it is often desirable to know the acoustic range of the noise source being measured. This is accomplished through the maximum L\text{eq} (L\text{max}) and minimum L\text{eq} (L\text{min}) indicators that represent the root-mean-square maximum and minimum noise levels measured during the monitoring interval. The L\text{min} value obtained for a particular monitoring location is often called the acoustic floor for that location.

To describe time-varying character of environmental noise, the statistical noise descriptors L_{10}, L_{50}, and L_{90} are commonly used. They are the noise levels equaled or exceeded 10 percent, 50 percent, and 90 percent of the measured time interval. Sound levels associated with L_{10} typically describe transient or short-term events. For the L_{50} descriptor, half of the sounds during the measurement interval are softer than L_{50} and half are louder. Levels associated with L_{90} often describe background noise conditions and/or continuous, steady-state sound sources.

Finally, another sound descriptor known as the day-night average sound level (L_{dn}) represents the average sound level for a 24-hour day and is calculated by adding a 10 dB penalty only to sound levels during the night period (10:00 pm to 7:00 am). The L_{dn} is typically used to define acceptable land use compatibility with respect to noise. Because of the time-of-day penalties associated with the L_{dn} descriptor, the L_{eq} for a continuously operating sound source during a 24-hour period will be numerically less. Thus, for a power plant operating continuously for periods of 24 hours, the L_{eq} will be 6 dB lower than the L_{dn} value.

Sound levels of typical noise sources and environments are provided in Table 4.1-1, Sound Levels of Typical Noise Sources and Noise Environments, to provide a frame of reference.

### 4.1.1.2 Noise Standards

WAC 463-62-030 states that energy facilities shall meet the noise standards established in chapter 70.107 RCW, the Noise Control Act of 1974 as implemented in the requirements in 173-60 WAC.

The WAC provides the applicable noise standards for Washington State. WAC 173-60 is adopted pursuant to the Noise Control Act of 1974, in order to establish maximum noise levels permissible in identified environments, and thereby to provide use standards relating to the reception of noise within such environments.
SCC Title 8 Chapter 22: Noise Regulations identifies limits and exceptions specific to noise in Skamania County. SCC 8.22 was adopted pursuant to, and is consistent with, WAC 173-60. Environmental designations for noise abatement (EDNA) are established in Section 8.22.080 and WAC 173-60-030. These rules establish maximum permissible environmental noise levels and are based on the EDNA, which is defined as an area or zone (environment) within which maximum permissible noise levels are established. There are three EDNA classes:

- Class A: Lands where people reside and sleep (such as residential)
- Class B: Lands requiring protection against noise interference with speech (such as commercial/recreational)
- Class C: Lands where economic activities are of such a nature that higher noise levels are anticipated (such as industrial/agricultural).

### 4.1.1.3 Affected Environment

#### Existing Sound Environment

The total project area encompasses approximately 1,152 acres in Skamania County, Washington. It is approximately seven miles northwest of the City of White Salmon, outside of the Columbia Gorge Scenic Area. The southernmost wind turbine is approximately 1.7 miles north of the Columbia River and is accessible by State Road 14 and Cook-Underwood Road.

As shown on Figure 4.1-1, Noise Level Contours, the two closest residences to the wind turbine tower locations are approximately 0.48 mile (2,560 feet) southeast of Tower A1 (shown on the figure as Receiver 1 or R1) and 0.8 mile (4,265 feet) southwest of Tower B16 (shown on the figure as Receiver 2 or R2). A potential future residence (shown as Receiver 3 or R3) is approximately 0.38 mile (2,000 feet) from Tower A1. Figure 4.1-1 shows that there are many potential receivers that are more distant from the project. To help establish representative baseline ambient sound levels for the project vicinity and characterize the existing noise environment in the areas occupied by the receivers shown in Figure 4.1-1, a set of long and short-term sound level measurements were conducted from January 20 to 22, 2009. The measurement locations included a position near the intersection of Ausplund Road and Kollack-Knapp Road (ST1), and a position near the intersection of Jessup Road and Manzanola Road (ST2). For purposes of the impact analysis described in this document, these measurement locations are considered reasonably representative for each general area, and more specifically R1 and R2, respectively, on the basis of similar expected ambient sound sources despite the dissimilarity of locations. For instance, the ambient sound environment measured at ST1 likely contains the same typical identifiable sound components (e.g., distant bird song, dog barks, roadway traffic) and a generally unidentifiable “background” that one might measure at the precise geographic location of R1.
Figure 4.1-1

Noise Level Contours

Whistling Ridge Energy Project
Skamania County, Washington

Job No. 33758687
A Bruel+Kjaer 2250 (SN: 2653963) ANSI Type-1 real-time sound analyzer, fitted with a standard microphone windscreen and mounted atop a five-foot tall tripod, was used for the short-term measurements. The instrument was field calibrated before and after each measurement period with an acoustic calibrator. All sound level measurements conducted by URS personnel were done so in accordance with ISO 1996a, b, and c. Weather conditions during the survey period were seasonally cold with overcast skies but no precipitation during the measurement periods. The air temperature varied from 30 to 44 degrees Fahrenheit, with 33 to 53 percent relative humidity. Measured ground wind speeds in the vicinity of the measurement positions were low, with averages ranging from 0 to 1 mph, and directed toward the north for all measurements. Detailed weather conditions for individual noise measurements and a summary of the short-term measurement data are included in Table 4.1-2.

A long-term measurement (LT1) was conducted at a position near the corner of Ausplund Road and Kollock-Knapp Road using a Larson Davis 720 (SN: 0436) ANSI Type 2 Integrating sound level meter. With only the windscreen-covered microphone exposed to the outdoor environment, the sound level meter was placed in a locked, weather-resistant case and secured to a nearby tree. The long-term measurement consisted of consecutive 15 or 30 minute averages conducted over an uninterrupted 24-hour period. The instrument was field calibrated before and after each measurement period with an acoustic calibrator (CAL 200 s/n: 5789). Data from the long-term measurement is presented in Table 4.1-3.

Field observations associated with the short and long term measurements are as follows:

**ST1.** This measurement location was at the corner of Ausplund Road and Kollock-Knapp Road. There are several residential receivers located in this area.

The first short-term measurement at this location was conducted between 11:52 am and 12:12 pm on January 21, 2009. The first measurement noise sources included distant aircraft, distant roadway traffic, dogs barking in the distance, and birds vocalizing. The second short-term measurement was conducted between 6:00 pm and 6:20 pm on January 21, 2009. The second measurement noise sources included distant aircraft, distant roadway traffic, and dogs barking in the distance. The third short-term measurement at this location was conducted between 11:32 pm and 11:52 pm on January 21, 2009. Noise sources during the third measurement included distant roadway traffic and dogs barking in the distance. The first measurement L_{eq} one-minute interval values ranged from 34 to 59 dBA, the second measurement 1-minute L_{eq} values ranged from 27 to 66 dBA, and the third measurement 1-minute L_{eq} values ranged from 25 to 49 dBA. L_{eq} for the entire duration of each of these three measurement periods appears in Table 4.1-2.

**ST2.** This measurement location was located in front of the John Schwab Memorial Tennis Courts on the corner of Jessup Road and Manzanola Road. The sound level meter was approximately 15 feet from Jessup Road.

The first short-term measurement at this location was conducted between 12:48 pm and 1:08 pm on January 21, 2009. The first measurement noise sources included distant aircraft, distant roadway traffic, children playing in the distance, and birds vocalizing. The second short-term measurement was conducted between 6:36 pm and 6:56 pm on January 21, 2009. The noise sources for the second short-term measurement included distant aircraft and distant roadway traffic. The third short-term measurement was conducted between 12:08 am and 12:28 am on January 22, 2009. Noise sources present during the third short-term measurement included distant roadway traffic. The first measurement L_{eq} one-minute values ranged from 35 to 52 dBA, the second measurement 1-minute L_{eq} values ranged from 34 to 54 dBA, and the third measurement 1-minute L_{eq} values ranged from 31 to 39 dBA. L_{eq} for the entire duration of each of these three measurement periods appears in Table 4.1-2.

**LT1.** This measurement location was at the corner of Ausplund Road and Kollock-Knapp Road, on the north side of the roadway. The sound level meter was placed in a tree near the side of the road.

Concurrent with these short and long term ambient sound measurements, S.D.S. Co., LLC meteorological stations 320, 321, and 323 collected data on wind speed, direction, and temperature at various elevations above grade. Average reported wind velocities from the station NRG Type 40 anemometers were quite low, and while apparently consistent with the low average wind velocities measured on the ground at the sound measurement positions, were considered potentially compromised by icy conditions due to the low recorded temperatures and high moisture content of the air.

Table 4.1-2 shows the considerable decibel differences between the L_{eq} measurements and the adjusted values when intervals containing documented automotive pass-by events (i.e., “without cars”) were removed from the short-term measurement data sets. This change is unsurprising due to the proximity of the real-time sound analyzer to the roadway at ST1 and ST2. Upon removing these intervals, the remaining collected data more accurately depicts the background or a measurement position that is considerably distant from passing road traffic.

Resulting from the application of a similar interval extraction technique to the concurrent LT1 data, Table 4.1-4 presents the arithmetic average L_{eq} of ST1 and LT1.
Table 4.1-4

The location of ST1/LT1 was selected to approximate the existing ambient sound in the vicinity of Ausplund Road and hence Receiver 1. Likewise, the location of ST2 was chosen to generally represent the ambient sound level for the Mill A community and its surroundings west of the project, on which Receiver 2 is located.

Applicable Impact Criteria

The project is sited entirely on a mixture of Commercial Forestry (GF1) Land and unzoned land (Nikki Holltitz, personal communication). Consequently, the environmental designation is considered to be EDNA Class C. Table 4.1-5 below illustrates the Class A (Residential) receiver noise level limitations for noise generated from a Class C (Commercial) EDNA (SCC 8.88.090, 100).1

Levels shown are at the property line of the receiving property and indicative of a source that is located in a Class C EDNA.

Notwithstanding the above and per 173-60-050 WAC, there are exemptions to the limits for certain noise-producing activities or source types as follows:

- Construction noise (including blasting) between the hours of 7 am and 10 pm
- Motor vehicles operated off public highways, except when such noise affects residential receivers

The reader should bear in mind that despite these exemptions, 173-60-50(6) WAC states, “Nothing in these exemptions is intended to preclude the Department from requiring installation of the best available noise abatement technology consistent with economic feasibility.”

---

1 Receiver locations 1 and 3 are in agriculturally zoned lands which would normally be classified as Class C EDNA. Receiver location 2 is residentially zoned. For the purpose of this analysis, because all 3 uses are residential, they have been classified as Class A EDNA.
4.1.1.4 Impacts

Construction

Project construction would take place over a period of 12 months between the hours of 7:00 am and 7:00 pm Monday through Friday. During construction activities, a varying number of construction equipment and personnel would occupy the project area, which would result in varying levels of construction noise. The project would use conventional construction techniques and equipment including (but not limited to), excavators, bulldozers, heavy trucks (e.g., water truck, dump truck), and similar heavy construction equipment. Specialized construction for logging and other tasks using heavy duty cranes and foundation building also may be needed.

Conventional construction activities would result in a short-term temporary increase in the ambient noise level resulting from the operation of construction equipment. The increase in noise level would be experienced primarily close to the noise source. The magnitude of the noise effects would depend on the type of construction activity, noise level generated by construction equipment, duration of the construction phase(s), and the distance between the noise source and receiver.

Construction noise impacts associated with the project were assessed with spreadsheet-based noise calculations. User inputs include:

- Distance from source—the distance between the edge of the construction site and the considered receiver
- Duty cycle—the portion of an hour, in aggregate, that a piece of equipment is energized (stationary or mobile) and creating noise
- Quantity—the number of equipment pieces or noise-producing events over a specific time period (e.g., equipment utilization per month)
- Hours—the number of daytime hours (up to 12) that represent a typical daily work shift

These inputs allow sound propagation prediction using the following formula:

\[ L_{eq} = \text{Source SPL} + 10 \cdot \log_{10} (\text{Duty Cycle}) + 10 \cdot \log_{10} (\text{Quantity}) + 10 \cdot \log_{10} (\text{Hours}/12) - 20 \cdot \log_{10} (\text{Distance from Source} / \text{Reference Distance}) \]

where source sound pressure level (SPL) and reference distance describe the typical noise, associated with a single piece of equipment, measured at a pre-defined distance. For instance, a chainsaw may have a source SPL of 78 dBA measured at a distance of 50 feet from its operator. Values for source SPL and reference distance have either been reproduced from available manufacturers’ data or calculated from industry-accepted formulas linking sound generation to the rated engine horsepower of the equipment. Note that for purposes of model conservatism, air and ground absorption effects are not included.
Table 4.1-6 shows the predicted construction noise levels experienced at the closest residences to
the project. As per 173-60-050 WAC, construction noise between the hours of 7:00 am and
10:00 pm are exempt from the receiver noise limit guidelines. Consequently, the calculated
values at the two closest receivers comply with the applicable noise standard.

</tbody>
</table>

If it is determined to be necessary, blasting would occur during the turbine foundation portion of
the construction schedule and only during daytime hours. Blasting noise could possibly be
audible at a considerable distance from the construction site and noticeable at residences near the
project area. Sound levels from blasting at a receiver would not be extreme, however, and the
occurrence would be low in frequency, intermittent and confined to a period of one to two
months. WAC 173.60.050 exempts temporary construction noise, including noise from blasting,
from the State noise limits between the hours of 7 am and 10 pm.

The large distances between much of the project area and potentially affected residences, the
temporary nature of construction, and the restriction of construction activities to daytime hours
would serve to minimize potential noise impacts from construction activities. Based on the
anticipated noise levels and the timing aspects of these impacts, construction noise impacts are
expected to be insignificant.

If project construction occurred in phases, the effect on the level of noise impacts would be to
extend the total duration of temporary disturbance from project construction, but to reduce the
intensity or magnitude of impacts for any individual phase. Construction noise impacts would
still be temporary, localized and low in magnitude, and overall project impacts during
construction would remain insignificant in a phased-construction scenario.

**Operation**

The Cadna/A® Noise Prediction Model (Version 3.71.125) was used to estimate the project-
generated sound pressure levels at the property lines and noise-sensitive receivers. Cadna/A® is
a Windows® based software program that predicts and assesses noise levels near industrial noise
sources based on ISO 9613-2 standards for noise propagation calculations. The model uses
industry-accepted propagation algorithms and accepts sound power levels (in dB re: 1 picowatt)
provided by the equipment manufacturer and other sources. The calculations account for
classical sound wave divergence, plus attenuation factors resulting from air absorption, basic
ground effects, and barrier/shielding. Intervening natural and man-made topographical barrier
effects were considered as appropriate, including those from structures such as major buildings, tanks, and large equipment.

Calculations were performed using linear octave band sound power levels as inputs from each pre-defined noise source, as summarized in Table 4.1-7: Noise Model Sound Level Parameters. Given that the exact turbine model to be use for the project has yet not been determined at the time of this report, conservative but realistic and representative values for the type of equipment being considered for this project have been used. For example, the model currently uses data from an industry leading 1.8 MW 50/60 Hz Wind Turbine, at wind speeds of about six meters per second and nine meters per second at 33 feet (10 meters), in accordance with the protocol established in International Electrotechnical Commission Standard 61400-11:2002. The decibel values shown for the two wind turbine generator wind speeds in Table 4.1-7 at each octave band center frequency include a +2 dB margin, which produces an A-weighted overall that represents the top end of a range associated with the manufacturer’s warranty values.

Source: URS internal information and Thomas Mills, personal communication

The project layout configuration (i.e., the arrangement of wind turbine generators and ancillary equipment on the site) was imported into Cadna/A® from project files provided by the client. Additional conservative measures were taken as the model assumed consistent 24-hour operation of the project. The Cadna/A model consequently predicts hourly sound levels, which would be equal at all times of day in this case. The formula used to derive the overall SPL (in dBA) from sound power level (PWL) is as follows:

\[
SPL = PWL - 20 \log (r) - 10.9 + C
\]

where \( r \) is in meters and \( C \) is a dimensionless absorption constant.2

The predicted operational noise levels at the three closest residences to the project are supplied in Tables 4.1-8 through 4.1-11. This analysis evaluates the existing noise levels at the closest receptors, and evaluates increases in dBA at these locations. The Washington noise regulations do not require this information. The Applicant is supplying this information to fully inform EFSEC.

---

Figure 4.1-1 depicts these three receivers (for the 9 m/s wind speed, 10°C temperature and 70% relative humidity operation case) in two detail maps as part of a larger aerial plan on which predicted noise contours and other known receiver locations have been superimposed. The operation of the project would comply with all applicable noise regulations.

Operation of the wind turbine generators is also capable of meeting the guideline criteria with respect to increase over ambient, but it depends on the ambient sound level and time of day.
Under certain conditions, there is the potential for one or more of the following phenomena to occur that may temporarily cause a variance in the predicted sound levels:

- In the Cadna/A prediction model, all studied wind turbine generators were assumed to operate at the same speed. In reality, very slight differences in operating rotor speeds due to non-uniformities in the passing wind profile can result in intermittent constructive and destructive interference—or what one might call “beats,” that can have a perceptible frequency as current research suggests.\(^3\)

- The atmosphere can either be “stable” or “unstable,” which in summary are descriptors for how layers of air mass interact. The latter of these two is usually associated with cold air near the ground that is not well coupled to higher air masses. This effect can explain why high wind speeds at wind turbine generator hub height can be substantially greater than those near ground level.\(^4\)

- The relative humidity and ambient temperature have a substantial effect on the attenuation of outdoor sound at high frequencies and long distances through air absorption. Relative humidity and temperature effects can produce a variance of approximately +/- 2dBA.

- The uncertainty range for the sound power level of each wind turbine generator is +/- 2dBA.

- Due to the very low ground wind speeds recorded during the short term measurements, actual ambient noise levels at any receiver in the project vicinity may be higher as a result of noise generated by turbulence from wind streaming through vegetative ground cover (i.e., trees and grasses).

None of these conditions would result in the project exceeding noise regulations.

**Low Frequency Sound**

Low frequency sound typically ranges from 100 Hz to 20 Hz, the latter of which is the generally understood limit audible to the human ear. Low frequency noise produced by a wind turbine generator can include tonal components produced by the generator and gearbox within the nacelle downstream of the rotor hub, atop the tower mast. The source sound power levels in Table 4.1-7 already include these noise contributors. Modern wind turbine design typically includes sound attenuation features in the nacelle to help reduce the magnitude of these electromechanical noise components to the aggregate, so that the spectrum of sound levels at the octave band center frequencies shown in Table 4.1-7 largely describes the aerodynamic effects of the rotor blades interacting with the passing wind profile.

In earlier generations of wind turbine design, the practice of downwind rotors allowed turbulence from the tower mast to disrupt favorable aerodynamic conditions for the passing blades, causing

---

\(^4\) Ibid., p. 158.
considerable low frequency noise. This practice has been abandoned by the contemporary upwind rotor design of virtually all wind turbine generators built in the past five years, including the models contemplated for this project. At the low frequency end of the spectrum, where ambient levels far exceed anticipated aggregate project operation noise.

The noise produced by air interaction with the rotor blades tends to be broadband noise, but is amplitude modulated as the upstream blades pass the tower, resulting in what some call a characteristic “swoosh.” The blade passage frequency of this “swoosh” is only a temporal modulation of sound and should not be confused with low frequency sounds. Virtually any sound can be time-modulated without changing its pitch. Thus, low frequency modulation of audible sound does not imply the presence of infrasound, which is discussed in the following paragraphs.

**Infrasound**

The term infrasound describes sound with frequencies of 20 Hz or less that are generally considered below the threshold of human hearing. Such sound, if sufficiently high in magnitude, can still be perceived or even heard as induced by vibration. Natural sources of infrasound include waves, thunder, wind, and even certain species of wildlife.

A review of wind turbine noise measurement studies conducted by Jakobsen (2005) concluded that operation of contemporary wind turbine generators featuring rotors “upwind” of tubular tower masts generated infrasound in the range of 70 G-weighted decibels (dBG) at a distance of one hundred meters.\(^5\) (The G-weighting scale, like the oft-used A-weighting scale for audible sound spectra, is a filter applied to low-frequency sound as described in ISO 7196:1995E.) Jakobsen also notes that this infrasound, usually associated with aerodynamic effects of blade passage past the tower mast, tends to ignore atmospheric sound absorption and ground attenuating effects due its very large wavelength. Hence, one could reasonably expect infrasound to attenuate only with increasing propagation distance.

Recent studies performed for the Canadian Wind Energy Association have described usage of 85–90 dBG as a criterion for human perception of infrasound and, by reasonable extension, the likely threshold for infrasound complaint.\(^6\)

The horizontal distances of the project wind turbines to the nearest noise-sensitive receivers are at least 615 meters, which provides sufficient attenuation to offset the amount of decibels that one might add to account for the quantity of wind turbines of the project. Thus, the expected infrasound at the nearest existing receivers (i.e., R1 and R2) should remain under an estimated value of 70 dBG, which is 15 dBG less than the previously stated criteria. This estimated project aggregate wind turbine generator infrasound level is also far below what NASA studies determined (125 dB, linear) as a threshold for potential health impacts.\(^7\) On these bases, infrasound potential impacts are considered to be either non-existent or less than significant.

---

4.1.1.5 Mitigation Measures

Construction

Construction would generally occur only during daytime hours to reduce the potential for noise impacts from this activity. Construction noise is exempt from Washington noise limits during daytime hours. To ensure that construction noise emission assumptions relied upon herein are valid and acoustical design goals are met by the project during construction, the following mitigation measures are proposed:

- All noise-producing project equipment and vehicles using internal combustion engines would be equipped with mufflers, air-inlet silencers where appropriate, and any other shrouds, shields, or other noise-reducing features in good operating condition that meet or exceed original factory specification. Mobile or fixed “package” equipment (e.g., arc-welders, air compressors) would be equipped with shrouds and noise control features that are readily available for that type of equipment.

- All mobile or fixed noise-producing equipment used on the project that is regulated for noise output by a local, state, or federal agency, would comply with such regulation while in the course of project activity.

- The use of noise-producing signals, including horns, whistles, electronic alarms, sirens, and bells, would be for safety warning purposes only. Unless required for such safety purposes, and as allowable by applicable regulations, no construction-related public address, loudspeaker, or music system would be audible at any adjacent noise-sensitive land use.

- The EPC Contractor would implement a noise complaint process and hotline number for the surrounding community. Whistling Ridge Energy LLC would have the responsibility and authority to receive and resolve noise complaints.

Operation

The noise modeling analysis indicated that the noise levels at the three closest residences (located 0.38, 0.48 and 0.8 mile away) would be 37 to 42 dBA for the 9 m/sec wind speed case, at and above which the wind turbine generators are expected to produce the most noise. With averaged measured existing sound levels reasonably representing ambient noise levels at these nearest noise-sensitive receivers, the cumulative increase over ambient for most operating cases would remain below applicable thresholds, and would result in no need for operation noise mitigation.
4.1.2 RISK OF FIRE OR EXPLOSION

Unlike thermal power plants, wind power projects pose a much smaller risk of explosion or fire potential, as there is no need to transport, store, or combust fuel to generate power. As with any major construction undertaking, construction of the project would present some fire risks. Fire risk mitigation starts with project design, especially with electrical design which needs to comply with the National Electric Code and the National Fire Protection Agency. A strict fire prevention plan would be enforced both during construction and operations to mitigate fire risks.

4.1.2.1 Fire and Explosion Sources

The risk of unintentional or accidental fire or explosion during both construction and operations would be minimal. As the project site is located within commercial forest and rangeland, the highest expected fire risks are forest fires and brush fires during the hot, dry summer season. Fire risk potential is constantly tracked and reported during the summer fire season by the WDNR and this would be actively posted at the construction job site during the high risk season. The project site roads act as firebreaks and also would allow quick access by fire trucks and personnel in the event of a grass fire. As is the case with almost any complex machines, there is some potential for fire inside the wind turbine generators.

4.1.2.2 Mitigation Measures

The construction manager would be responsible for staying abreast of fire conditions in the project area by contacting WDNR and implementing any necessary fire precautions. A Fire Protection and Prevention Plan would be developed for EFSEC approval and implemented, in coordination with the Skamania County Fire Marshall and appropriate agencies. Table 4.1-12 lists sources of potential fire and explosion along with measures to mitigate the risk of either occurring.

Lightning-induced fires are rare in the project area and both the wind turbine generators and the substation are equipped with specially engineered lightning protection systems. With the types of modern wind turbines proposed for the project, however, turbine malfunctions leading to fires in the nacelle are extremely rare. The turbine control system detects overheating in turbine machinery, and internal fires would be detected by these sensors, causing the machine to shut down immediately and send an alarm signal to the central SCADA system, which would notify operators of the alarm by cell phone or pager.

The potential fire risks are similar in nature but lower for project decommissioning. Fire prevention measures during decommissioning would be similar to those for project construction.

- a. Indicated risk during construction (C) and/or operations (O)

4.1.3 RELEASES OR POTENTIAL RELEASES TO THE ENVIRONMENT AFFECTING PUBLIC HEALTH

4.1.3.1 Construction

Diesel fuel would be the only potentially hazardous material used in any significant quantity during construction of the project. Construction of the project would require the use of diesel fuel for operating construction equipment and vehicles. Measures to prevent and contain any accidental spills resulting from this fuel storage and use are described in detail in Section 2.9, Spillage Prevention and Control. Construction of the project would not result in the generation of any hazardous wastes in quantities regulated by state or federal law. During construction, the primary wastes generated would be solid construction debris such as scrap metal, cable, wire, wood pallets, plastic packaging materials and cardboard. The total volume of construction wastes is expected to be less than ten tons. This waste would be accumulated on site in drop boxes until hauled away to a licensed transfer station or landfill by either the EPC contractor or the Skamania County Solid Waste Division.
4.1.3.2 Operations

Operation of the project would not result in the generation of regulated quantities of hazardous wastes. As no fuel would be burned to power the wind turbine generators, there would be no spent fuel, ash, sludge or other process wastes generated. The primary type of waste generated by operations the project would be municipal solid waste generated at the Operations and Maintenance facility, consisting of typical office wastes (paper, cardboard, food waste, etc.), which would be stored in a dumpster until it is collected by the Skamania County Solid Waste Division. Periodic changing of lubricating oils and hydraulic fluids used in the individual wind turbine generators would result in the generation of small quantities of these materials. These waste fluids would be generated in small quantities because they need to be changed only infrequently and the changing of these fluids is not done all at once, but rather on an individual basis. These waste fluids would be stored for short periods of time in appropriate containers at the Operations and Maintenance facility for collection by a licensed collection service for recycling or disposal. Procedures for collecting, storing and transporting these materials for recycling or disposal are described in detail in Section 2.9, Spillage Prevention and Control.

4.1.4 SAFETY STANDARDS COMPLIANCE

Whistling Ridge Energy LLC and its contractors would comply with all applicable local, state and federal safety, health, and environmental laws, ordinances, regulations, and standards (Appendix D). Some of the main laws, ordinances, regulations and standards that would be reflected in the design, construction, and operation of the project are as follows:

- Occupational Safety And Health Act Of 1970 (29 USC 651, et seq.) and 29 CFR 1910, Occupational Safety and Health Standards
- Uniform Fire Code
- Americans with Disabilities Act
- Uniform Fire Code Standards
- Uniform Building Code
- National Fire Protection Association, which provides design standards for the requirements of fire protection systems
- National Institute For Occupational Safety And Health, which requires that safety equipment carry markings, numbers, or certificates of approval for stated standards
- American Society Of Mechanical Engineers, which provides plant design standards
- American National Standards Institute, which provides plant design standards
- National Electric Safety Code
- American Concrete Institute Standards
American Institute of Steel Construction Standards
American National Standards Institute
American Society for Testing and Materials
Institute of Electrical and Electronic and Installation Engineers
National Electric Code

4.1.4.1 Blade Throw

Blade throws were common in the industry’s early years, but are unheard of today because of better turbine design and engineering (AWEA 2008). While cases of blade drop/throw have occurred, these incidents are rare and have generally been linked to improper assembly or exceedance of design limits. Modern turbine braking systems, pitch controls, and other speed controls should prevent exceedance of design limits (AWEA 2008).

4.1.4.2 Tower Failure

Reasons for collapse can vary depending on conditions and tower type, but may include blade strikes, very strong winds, and improper maintenance. While structural failure is more damaging than blade failure, the consequences and risks to human health are far lower since risks are confined to within a relatively short distance from the turbine (Caithness 2006).

There is only one recorded death from a tower collapse, which occurred in Sherman County, Oregon. A six-month investigation found that the operating company “failed to properly instruct and supervise workers in the safe operation of tools and equipment. It also found that company procedures for working under potentially dangerous conditions fell short of OSHA [Occupational Safety and Health regulations” (Hill 2008). The investigation did not find any structural problems with the tower itself.

4.1.4.3 Ice Throw

Ice storms, both mild and occasionally severe, may occur within the project area (see Section 2.1.3.2, Climate). During periods of ice build-up, the exposed parts of the turbine may be coated with ice. According to the AWEA, “the moving turbine rotor is liable to accrete heavier quantities of ice than the stationary components of the wind turbine” (AWEA 2008). Most modern turbines include sensors that will shut down the turbine when ice build-up is detected.

If the ice on the moving rotor is cast off, it could pose a threat to people, animals and buildings on the ground. However, the same setbacks used to minimize noise are sufficient to protect against danger to the public. The results of a questionnaire sent to a large number of wind turbine operators found most fragments found on the ground measured approximately 0.2–2.2lbs within an area of approximately 49–328 feet from the wind turbines (Morgan et. al. 1998). Anecdotal evidence suggests that ice tends to drop off the rotor, rather than being thrown off. Also, ice tends to shed more from the blade tips, and larger pieces of ice debris tend to fragment in flight.
4.1.5 RADIATION LEVELS

Pursuant to WAC 463-60-115, Whistling Ridge Energy LLC requests a waiver of the information required by WAC 463-60-352(5), which call for information relating to radioactivity. No radioactive materials would be used, consumed, or released during construction or operation of the project.

4.1.6 EMERGENCY PLANS

The Emergency Plan for the project would consider the actions and responsibilities of personnel and off-site assistance groups during situations that may require physical corrective actions. The plan would include procedures designed to outline preventive measures for specific conditions that could evolve into an emergency situation, and outline procedural methods for mitigating an emergency should one occur.

The fundamental objective of the plan is to provide the necessary prearrangements, directions, and organizational structure such that all plant emergencies can be effectively and efficiently resolved to safeguard the public, plant personnel, and property.

In all instances associated with this plan, the manager or designee would be responsible for taking immediate action to safeguard the public, plant personnel, the environment, and equipment. The protection of personnel, the public, and the environment would always take precedence; plant systems and equipment would be secondary. In any situation the more conservative approach would always be considered.

4.1.6.1 Responsibility and Authority

The Whistling Ridge Energy Project would be staffed with at least one on-site manager. Off-site, the project would be supported by the Project Manager under the auspices of Operations and Maintenance services, corporate regulatory services, and corporate safety.

The responsibility and authority for day-to-day operations would be delegated to the manager and, as such, the manager would have direct responsibility to ensure that all routine and emergency site operations are conducted in a manner to protect the public, the environment, personnel and equipment. Overall responsibility and authority shall remain with the manager, or designee. The manager would ensure implementation and compliance with the plan and component procedures, direct emergency response actions, account for personnel, and direct evacuation actions as appropriate.

The individual employee would be responsible for being knowledgeable of the general guidance provided in the current Emergency Plan and its component procedures, for actively participating in drills and training in support of the plan and procedures, and for complying with policies set forth in the plan and procedures. Each employee would be responsible for notifying the manager of any potentially dangerous situation of which he or she has knowledge, and of any emergency situation (e.g., fire, oil spill, vehicle accident). The manager would notify the Project Manager and others as necessary to comply with the plan and procedures.
4.1.6.2 Components of the Emergency Plan

The following procedures would be components of the Emergency Plan.

- Fire Plan
- Personal Injury Response Plan
- Safety Plan
- SWPPP
- SPCC Plan
- Hazardous Waste Management Plan

Other Emergency Situations

Meteorological. This type of emergency includes hail, high winds, thunderstorms, extreme cold weather, and any other naturally occurring weather situation that may endanger, equipment, or require adjustments to the normal operations of the facility. Depending on the specific hazard, and available information, it is the responsibility of the manager or his designee to take the appropriate action to safeguard the public, the environment, personnel, the facility and its equipment.

Geological. This type of emergency deals with seismic activity and related geological phenomena. Depending upon the specific details available, it is the responsibility of the manager or his designee to take the appropriate action to safeguard the public, the environment, plant personnel, the plant and its equipment.

Man-Made. This type of emergency includes bomb threats, civil unrest, sabotage, or any other man made threats to the facility or personnel. This type of emergency must first be validated using the following criteria:

- Source of the information
- Reliability of the information
- Ability to confirm the information

Once the information has been validated then the decision must be made whether it would impact the facility or not. Once the decision is made, it is the responsibility of the manager or his designee to take the appropriate action to protect the public, the environment, plant personnel, the plant and its equipment, or to limit the impact on these elements.

The manager would coordinate response actions with the Skamania County Sheriff’s office and Whistling Ridge Energy Project personnel, and provide support as requested and available.
**Equipment Failure.** This type of emergency is primarily failure of equipment that may result in hazards to personnel.

**4.1.6.3 Reporting Requirements to the Energy Facility Site Evaluation Council**

Conditions affecting the safety of the project, including any condition, event, or action that might compromise the safety, stability, or integrity of any facility or the ability of any equipment to function safely; or that might otherwise adversely affect the life, health, or property, would be reported to EFSEC.

Any condition affecting project safety would be reported orally to the EFSEC contact by the manager as soon as practicable after that condition is discovered. A written report would be submitted to EFSEC within the time specified by the EFSEC, and would contain any information EFSEC directs, including:

1. The causes of the condition
2. A description of any unusual occurrences or operating circumstances preceding the condition
3. An account of any measure taken to prevent worsening of the condition
4. A detailed description of any damage to the facility and the status of any repair
5. A detailed description of any personal injuries
6. A detailed description of the nature and extent of any private property damage
7. Any other relevant information requested by EFSEC

**4.1.6.4 Review and Updating**

The Emergency Plan would be reviewed annually, and changes made during the annual review or anytime a significant change has occurred in the information contained in this plan. The manager would be responsible for scheduling the annual review and having the plan and procedures updated as needed. The procedures would also be reviewed and revised as necessary, to reflect lessons learned from accidents, emergency situations, and tests of the procedures.

**4.1.6.5 Training and Drills**

Site personnel involved in emergency plan procedures would be trained annually and would be documented. Training would include a review of procedures, definitions, and regulations. All new employees would receive training as part of their orientation. Staff would periodically test emergency plan procedures by either performing a table top drill or, where practicable, a field drill. If necessary, as a result of the drill(s), procedures would be revised to take advantage of lessons learned.
4.1.6.6 Agreements Related to Emergency Planning

Prior to construction of the project, Whistling Ridge Energy LLC would develop agreements related to emergency planning with Skamania County Emergency Medical Services. This agreement would be provided to EFSEC and attached to the Emergency Plan prior to implementation.
SECTION 4.2 LAND AND SHORELINE USE  
(WAC 463-60-362)

This section addresses the land and shoreline use issues applicable to the proposed Whistling Ridge Energy Project and includes the following subsections:

- Land Use (Section 4.2.1)
- Light and Glare (Section 4.2.2)
- Aesthetics (Section 4.2.3)
- Recreation (Section 4.2.4)
- Historic and Cultural Preservation (Section 4.2.5)
- Agricultural Crops/Animals (Section 4.2.6)

4.2.1 LAND USE

Skamania County is governed by two independent sets of development regulations. The first is a stand-alone zoning code (SCC Title 22) that regulates uses and development within the Columbia River Gorge National Scenic Area GMA and SMA. The Scenic Area Code is based on the Management Plan for the Scenic Area, which is overseen by the USFS and Columbia River Gorge Commission, as directed by the National Scenic Area Act. The remainder of unincorporated Skamania County, including Scenic Area Urban Areas, is governed by zoning regulations in SCC Title 21 and related Titles 20 Shorelines and 21A Critical Areas. The proposed project site and access road (West Pit Road) are regulated by SCC Titles 20, 21 and 21A, but the access roadways up to the project boundary are not. Neither of the site or West Pit Road are regulated by SCC Title 22 Scenic Area. The site and access roadways are evaluated separately together with respect to land use in Sections 4.2.1.2 and 4.2.1.3.

4.2.1.1 Existing Land Uses

Existing Land Use Conditions

The project site has been in commercial forest use for the last century. During this time, the owners and operators have logged the property over a series of approximately 50-year logging rotations. The property is permanently committed to commercial tree farming and harvesting. Regardless of whether the wind energy facility is built, the project area will be, and will remain in, commercial forestry production. Ongoing activities will include regular clearing, replanting, and harvesting. The purpose of this project is to introduce an additional and compatible land use (wind energy generation), timed and implemented in sync with ongoing commercial forestry operations and rotations. This combination of natural resource uses (logging and renewable, clean wind energy production) is intended to better diversify the use of the property and the Skamania County economy as a whole. This diversification would ensure ongoing commercial
forestry in concert with another natural resource-based land use that would better insulate the Applicant from economic cycles that have undermined similar timber operations both in the county and the Pacific Northwest as a whole, compelling multiple, large, irreversible conversions to residential, resort, and other uses.

The project would be sited within an existing utility corridor. There are two large, lattice electrical towers, four high-voltage transmission lines, two communications towers, a natural gas pipeline, and a rock pit to supply materials for forest road maintenance and construction within the project’s immediate vicinity (see Figure 2.1-1 in Section 2.1). The proposed Whistling Ridge Energy Project would be connected to the existing BPA transmission lines and would be consistent with existing utilities and commercial timber operations.

To maximize the project’s compatibility with ongoing timber harvest and other forestry operations, a number of design features have been incorporated into the project. For example, some of the turbine corridors would be sited on ridgelines to minimize clearing while maximizing wind exposure; existing private forest roads would be used for access to minimize new construction; and forest rotation length and tree heights have been factored into the design life of the project so that it would be compatible with tree growth rates in surrounding forest blocks. As noted above, the project would help diversify the income potential from these forest lands while minimizing conversion to other uses.

Other uses permitted within the For/Ag-20 and R-10 zones include telecommunication facilities, log storage and sorting areas, scaling stations, temporary crew quarters, forest industry storage and maintenance facilities, farm use, single-family dwellings for farm or forest operators, home occupations, rooftop wind turbines, small-scale solar energy systems, and management of fisheries, biological areas, and conservations areas. Further, Washington’s Forest Practices Act allows timber harvest and surface mining as part of commercial forest practices.

The proposed alternative 5-acre Maintenance and Operations facility would be located on land zoned Residential 5 (R-5), a zoning requiring a minimum of 5 acre sites. In addition to residential, other non-residential uses permitted outright in the R-5 zone include commercial and domestic agriculture, forestry, and public facilities and utilities. Non-residential uses allowed by conditional use approval include surface mining, recreational facilities, professional services, geothermal energy facilities, semi-public facilities, small and large-scale recreational vehicle parks, and child day care centers.

Land Uses within 25 Miles of the Site

To consider the proposed land use of wind energy in a broader context, land uses within 25 miles of the site were considered. The area encompassing a 25-mile radius of the site is transected east-west by the Washington-Oregon border, Columbia River Gorge, Columbia River Gorge National Scenic Area, SR 14, BNSF Railway, the Columbia River, and I-84 (on the Oregon side of the Columbia River). The Gifford Pinchot National Forest is located north of the project in Washington State (Figure 4.2-1, Land Uses within 25 Miles of Site).
Figure 4.2-1
Land Uses Within 25 Miles of Site

Source: GeoDataScape.
On the Washington side of the Columbia River, land use is predominantly commercial forestry and residential in numerous small, unincorporated communities. There is some limited agriculture, mostly pear and apple orchards recently augmented with some wine grape vineyards, within the Scenic Area. On the Oregon side of the Columbia River land use in the Scenic Area is predominantly commercial timber production and residential. South of the Scenic Area, on the Oregon side, land uses include commercial forestry, agriculture, and some residential. The primary Oregon orchard crops are pears, apples, and cherries. The project is not located near or on any shorelines of State, County or other significance.

The project is located in Skamania County, but is adjacent to Klickitat County to the north. The incorporated cities of White Salmon and Bingen are located approximately 7 miles southeast of the site on and near the Columbia River. The Skamania County seat is located in the incorporated city of Stevenson, approximately 15 miles southwest along the Columbia River. Directly south and across the Columbia River from Bingen is the city of Hood River, Oregon. These incorporated cities have mixed urban uses, but their populations remain low, as do the overall populations of Skamania and Klickitat Counties (Table 4.2-1).

The Scenic Area extends 85 miles along the Columbia River and includes portions of three Oregon and three Washington counties. The project site is located roughly north of the center of the Scenic Area on the north side of the Columbia River. The National Scenic Area Act designated for special protection 292,500 acres on both sides of the Columbia River from the outskirts of the Portland-Vancouver metropolitan area in the west to the semi-arid regions of Wasco and Klickitat counties in the east. Although both the project site and the access road are located completely outside the Scenic Area, the proposed Whistling Ridge Energy Project does extend up to its outermost boundary, and access is through the Scenic Area. Scenic Area access roads already exist, but require improvement for the delivery of components and related equipment into the project site (See Section 4.3 Transportation for further details on road improvements).

Recreation facilities in the vicinity of the development are discussed in Section 4.2.4.
Impacts to Existing Land Uses

Construction

During construction at the development site, earth movement and construction-related traffic would generate noise and dust that would impact nearby businesses. Impacts and mitigation related to dust, noise, and traffic during construction are addressed in Sections 3.2, 4.1, and 4.3, respectively.

Operation

The Whistling Ridge Energy Project would provide approximately 75 MW of renewable energy resources. Wind energy has been proven to be a safe, effective, and efficient use of alternative energy. No negative impacts to existing or planned land uses are anticipated.

On the Washington side of the Columbia River, land use is predominantly commercial forestry and residential in numerous small, unincorporated communities. There is some limited agriculture, mostly pear and apple orchards recently augmented with some wine grape vineyards, within the Scenic Area. On the Oregon side of the Columbia River land use in the Scenic Area is predominantly commercial timber production and residential. South of the Scenic Area, on the Oregon side, land uses include commercial forestry, agriculture, and some residential. The primary Oregon orchard crops are pears, apples, and cherries. The project is not located near or on any shorelines of State, County or other significance.

The wind turbines would likely be painted a non-reflective flat neutral gray or light color to blend in with the natural setting and the sky. Visual impacts are addressed in Section 4.2.3.

The project’s electrical system would consist of two key elements: 1) a collector system, which would collect energy generated at 575 volts from each wind turbine, transform the voltage to 34.5 kV using a pad-mounted transformer, and deliver the energy via underground collector cables to 2) the project substation, which would further transform the energy delivered by the underground collector system from 34.5 kV to 230 kV and deliver it to the adjacent BPA transmission line and into the regional transmission system. If unforeseen physical constraints prohibit underground placement of all lines, aboveground lines would be required.

Permanent Operations and Maintenance facilities would be constructed on an approximately 3.15-acre site located either adjacent to the substation, or west of the project area along West Pit Road. Facilities would likely include office and workshop areas, a kitchen, bathroom, shower, and utility sink. At least one structure would be constructed of sheet metal, and would be approximately 16 feet tall (to the roof peak) and enclose approximately 3,000 square feet. A graveled parking area for employees, visitors, and equipment would be located adjacent to the building. The entire area would be fenced and have a locked gate.

Security lighting would be minimized and directed downward and toward the facilities to protect from light spill over onto adjacent properties.
The project would operate in compliance with applicable Washington State Environmental Noise Levels, Chapter 173-60 WAC.

If the project were terminated, the necessary authorization from the appropriate regulatory agencies would be obtained to decommission the facilities in accordance with the approved Site Restoration and Decommissioning Plan. All aboveground facilities would be removed from the site, and unsalvageable material would be disposed of at authorized sites. To avoid environmental damage and unnecessary land disturbance, the underground collector cables likely would be retired in place, and turbine foundations would be removed to a depth of approximately four feet bgs, with the remainder likely retired in place.

The soil surface would be restored as close as reasonably possible to its original condition. Reclamation procedures would be based on site-specific requirements and forest management techniques commonly employed at the time the area is to be reclaimed, and would include regrading, adding topsoil, and replanting of all disturbed areas. Decommissioned roads would be reclaimed or left in place based on landowner preference, and right of way would be surrendered to the landowner.

4.2.1.2 Relationship of Project Site to Existing Land Use Plans and Policies

2007 Comprehensive Plan

The proposed Whistling Ridge Energy Project site is located within Skamania County. On July 10, 2007, Skamania County adopted its current Comprehensive Plan, which includes three Subarea Plans (Figure 4.2-2 Comprehensive Plan Designations). The project site is not located in one of these subareas. There are three land use designations outside of the specific subarea plans: Rural I, Rural II, and Conservancy. The project area is designated as “Conservancy.” Table 2-1 of the Comprehensive Plan identifies zones that are consistent with the Conservancy designation, including: Residential 10 (R-10), Rural Estates 20 (RES-20), Forest Land 20 (FL 20), Commercial Resource Land 40 (CRL 40), Natural (NAT) and Unmapped (UNM). The project site is located in the FL 20, R 10, and UNM zones, all of which are consistent with the Conservancy designation. The alternative Operations and Maintenance facility site would be located in the R-5 zone, a zone shown as consistent with the Rural II designation. The project site also is located adjacent to (but not within) southwestern Klickitat County (see Figure 4.2-3, Klickitat County Land Use Designations). In a letter to EFSEC, dated May 4, 2009, Karen Witherspoon, Skamania County Community Development Department Director, found that the proposed project is consistent with the Skamania County Comprehensive Plan, and resource maps. A similar letter has been requested regarding the alternative location of the Operations and Maintenance facility.

The overall Skamania County comprehensive plan vision statement is:

“Skamania County is strongly committed to protecting our rural character and natural resource based industries while allowing for planned future development that is balanced with the protection of critical resources and ecologically sensitive areas, while preserving the community’s high quality of life.”
Figure 4.2-2

Comprehensive Plan Designations

Whistling Ridge Energy Project
Skamania County, Washington
Figure 4.2-3
Southwestern Klickitat County
Land Use Designations

Source: Klickitat County.
Job No. 33758687
Natural resources based industry is further encouraged in the Conservancy land use designation. Beginning on page 25 of the Comprehensive Plan is a description of the intent of the Conservancy designation:

“The Conservancy land use area is intended to provide for the conservation and management of existing natural resources in order to achieve a sustained yield of these resources, and to conserve wildlife resources and habitats. Much of the Conservancy land use area is characterized by rugged terrain, steep in slope, and unsuitable for development of any kind. Logging, timber management, agricultural and mineral extraction are main use activities that take place in this area. Recreational activities of an informal nature such as fishing, hunting, and hiking occur in this area, although formal recreational developments may occur from time to time. Conservancy areas are intended to conserve and manage existing natural resources in order to maintain a sustained resource yield and/or utilization.”

The land proposed for the project is in an area of rugged terrain and steep slopes. The land is used primarily for logging and timber management. Informal recreation activities take place in the area of the proposed project, although access to the project site for these activities is limited by the Applicant. The Whistling Ridge Energy Project would be consistent with the Comprehensive Plan vision and the Conservancy designation, in that it would conserve and manage existing natural forest and wind resources to maintain a sustained yield and utilization of both.

Among the uses identified by the 2007 Comprehensive Plan as appropriate in the Conservancy designation are: public facilities, utilities, utility substations, forest management (including temporary logging and mining camps), and surface mining (by conditional use). Wind energy facilities are consistent with the Conservancy designation because they are utilities. The project would provide an alternative source of electrical energy generation that is not reliant on either fossil fuels or hydropower, while allowing forest management activities to continue around the turbine corridors. The Whistling Ridge Energy Project would be a utility consistent with the Conservancy designation’s appropriate uses.

The use of Rural II land is described beginning on page 24 of the Comprehensive Plan:

“The Rural II land use area is intended to provide for rural living without significant encroachment upon lands used for agriculture and timber. This land use area is the middle developmental range level suggested by this plan. The lower density will help to protect agricultural and timber lands from dense residential type development, and should maintain the rural character of this designation.”

The Operations and Maintenance facility would include an approximately 3,000 square foot building, located on a 5-acre parcel in an area designated as Rural II in the Comprehensive Plan. The facility would be similar in size to a larger single family home. Among the non-residential uses identified in the 2007 Comprehensive Plan as appropriate in the Rural II designation are: public facilities, utilities, utility substations,
telecommunication facilities, hospitals, meeting halls, agriculture, forest management, including temporary logging and mining camps, and surface mining.

The project would not be in conflict with any of the goals or policies expressed in the 2007 Comprehensive Plan. A number of these specifically encourage projects similar to the Whistling Ridge Energy Project:

**Land Use (beginning on page 26 of the Comprehensive Plan)**

**Goal LU.1:** To integrate long-range considerations (comprehensive planning) into the determinations of short-term action (individual development applications).

*Policy LU.1.2:* The plan is created on the premise that the land use areas designated are each best suited for the uses proposed therein. However, it is not the intention of this plan to foreclose on future opportunities that may be made possible by technical innovations, new ideas and changing attitudes. Therefore, other uses that are similar to the uses listed here should be allowable uses, review uses or conditional uses, only if the use is specifically listed in the official controls of Skamania County for that particular land use designation.

**Goal LU.2:** To provide for orderly future physical development of Skamania County.

*Policy LU.2.4:* Encourage new commercial enterprises to locate within or near existing commercial areas to avoid further scattering and to better serve the public.

**Goal LU.3:** To coordinate public and private interests in land development.

*Policy LU.3.3:* Encourage industry that would have minimal adverse environmental or aesthetic effects.

**Goal LU.4:** To promote interagency cooperation and effective planning and scheduling of improvements and activities so as to avoid conflicts, duplication and waste.

*Policy LU.4.3:* Land use patterns, which minimize the cost of providing adequate levels of public services and infrastructure, should be encouraged.

**Goal LU.5:** To promote improvements which make our communities more livable, healthy, safe and efficient.

*Policy LU.5.5:* Promote compatibility of industry with the surrounding area or community by fostering good quality site planning, landscaping, architectural design, and a high level of environmental standards.

*Policy LU.5.6:* Encourage commercial development that is convenient, safe and pleasant to the general public by: requiring that new establishments provide off-street parking adequate for its needs. Encourage pooled or joint use parking areas for adjacent developments may be utilized; Regulate access points for vehicular traffic for commercial areas to prevent unsafe conditions; the design of commercial sites, buildings,
and signs should be compatible with surrounding areas; and, landscaping may be required as a buffer when commercial use adjoins residential or farm property.

**Environmental (beginning on page 43)**

Goal E.1: To ensure the proper management of the natural environment to protect critical areas and conserve land, air, water, and energy resources.

**Transportation, Public Facilities and Services (beginning on page 58)**

Goal T.1: Transportation – Encourage an efficient multi-modal transportation network that is based on regional priorities and coordinated with county and city comprehensive plans.

Goal T.2: Continue the priority of increasing safety of the Skamania County rural 2-lane road system. The majority of the Public Works Department’s future efforts will be to reduce the accident rate with Skamania County.

Goal T.3: Public Facilities and Services – Ensure that those public facilities and services necessary to support development should be adequate to serve the development at the time the development is available for occupancy and use without decreasing current service levels below locally established minimum standards.

**Archeology and Historic Preservation (beginning on Page 68)**

Goal AHP.1: Identify and encourage the preservation of lands, sites, and structures that have historical or archaeological significance.

Goal AHP.2: Increase recognition of historic, archaeological, and cultural resources.

Goal AHP.3: Protect historic, archaeological and cultural resources through a comprehensive planning approach.

**Skamania County Code, Title 21 Zoning**

At the time of this Application, the existing SCC Title 21 remains in effect. However, extensive updates have been proposed for adoption, but they are under appeal by local interest groups and so are indefinitely on hold. The project site’s relationship to the existing Title 21 zoning is discussed in this section. Even though not in effect or even in a final form, a discussion of the project site’s relationship to the most recent version of the proposed Title 21 zoning update is presented in Appendix E to demonstrate the Whistling Ridge Energy Project would be consistent with both. In a letter to EFSEC, dated May 4, 2009, Karen Witherspoon, Skamania County Community Development Department Director, found that the proposed project is consistent with SCC Title 21 Zoning Code, SCC 21A Critical Areas, Title 24 Clearing and Grading, the Comprehensive Plan, and resource maps.

Approximately 400 acres of the 1,152-acre site are within areas zoned Resource Protection (For/Ag-20) and Residential 10 (R-10) by Skamania County. Turbine corridor A1-A7 with approximately seven turbines is proposed in these areas. The proposed alternative Operations
and Maintenance facility located along West Pit Road would be within an area zoned Residential 5 (R-5). The existing SCC Title 21 would require a conditional use permit for both the A1-A7 turbine corridor and the alternative location along West Pit Road for the Operations and Maintenance facility. A letter similar to the County’s May 4, 2009 Certificate of Land Use Consistency has been requested regarding the alternative location for the Operations and Maintenance facility and will be provided to EFSEC.

The remainder of the project site is in the UNM zone. In UNM zones wind energy facilities would be outright permitted uses (Figure 4.2-4 Skamania County Zoning). “In the UNM zone all uses which have not been declared a nuisance by statute, resolution, ordinance or court of jurisdiction are allowable. The standards, provisions, and conditions of this title [SCC Title 21] shall not apply to unmapped areas (SCC 21.64.020).” SCC 8.30.010 enumerates the sum total of the nuisances established by the Board of County Commissioners by resolution and ordinance.

Neither the RCW nor the WAC includes statutes designating wind energy facilities as a nuisance. Such facilities have not been designated a nuisance in any court of jurisdiction.

The project would conform to the purpose and intent outlined in current zoning code for each of the three zones in which it would be located. The purpose of each applicable zone is listed below:

- **Residential 10 (R-10)** - “The R-10 zone classification is intended to provide a transition zone of low density rural residential development which will maintain the rural character of areas within the rural II and conservancy land use areas of the county comprehensive plan” (SCC 21.40.010).

- **Residential 5 (R-5)** – “To provide a transition zone of medium to low density residential development which will maintain a rural character of the area in the Rural II Land Use Area of the County Comprehensive Plan A.” (SCC21.36.010).

- **Resource Production (For/Ag-20)** - “To provide land for present and future commercial farm and forest operations in areas that have been and are currently suitable for such operations, and to prevent conflicts between forestry and farm practices and nonresource production uses by not allowing inappropriate development of land within this zone classification” (SCC 21.56.010[A]).

- **UNM** – “The provisions of this chapter shall apply to all zone classifications (except for the unmapped classification) unless otherwise noted in a particular zone classification” (SCC 21.70.010).
In the surrounding area between Underwood Mountain and the Little White Salmon River, the predominant land use is commercial forestry. East of the Little White Salmon River, there is some land zoned Residential (R-2, R-5, and R-10). However, all of the R-10 and R-5 lands, and most of the R-2 lands, are currently being used for commercial timber production under ownership by S.D.S. Co., LLC, Broughton Lumber Company, and Washington State. The Washington State lands are managed by WDNR for commercial harvest to support the State’s schools.

West of the Little White Salmon River are the unincorporated rural communities of Mill A and Willard. Mill A is located at least 1.5 miles from the nearest turbine corridor and Willard is at least 2.25 miles north of the nearest turbine corridor. Both Mill A and Willard are predominantly zoned Residential (R-2 and R-5).

Skamania County has been updating its comprehensive plan and existing Title 21 zoning since 2005. In July 2007, the County adopted a moratorium on unincorporated UNM-zoned lands outside the Swift Subarea. The moratorium does not prohibit all development in UNM lands. Rather, it restricts three types of land uses: 1) issuance of building permits on lands created by deed since January 2006 that are 20 acres or larger; 2) land divisions (short plat and subdivision); and 3) acceptance of SEPA checklists in support of converting land to non-forestry uses. The project is not sited on lands created by deed since January 2006 and does not involve any land division. Because of EFSEC’s well-established preemptive role in permitting wind energy facilities, including acting as Lead Agency for associated SEPA review, the County’s moratorium on acceptance of SEPA checklists for forest practices conversions does not affect the project.

**Conditional Use Approval**

The R-10-5 and For/Ag-20 zones list semi-public utilities as conditional uses under SCC 21.40.030(G) and SCC 21.56.030(C), respectively. Semi-public utilities are defined in SCC 21.08.010 as “facilities intended for public use which may be owned and operated by a private entity.” Thus, the proposed Whistling Ridge Energy Project would be a semi-public utility under SCC Title 21 with turbine corridor A1-A7, located partially in the R-10 and partially in the For/Ag-20 zones, and the alternative Operations and Maintenance facility along West Pit Road located in the R-5 zone (Figure 4.2-3, Klickitat County Land Use Designations, Skamania County Zoning). Absent EFSEC review, the A1-A7 turbine corridor and the alternative location for the Operations and Maintenance facility along West Pit Road would be subject to the conditional use provisions outlined in SCC 21.16.070, as amended in Ordinance 2007-02. The zoning code would require a determination of whether the proposed use is compatible with existing or permitted uses in the specific area according to six criteria. Conditions may be imposed based on the health, safety, and general welfare of the public, any environmental standards in force, and provisions of SCC Title 21. The conditional use permit criteria that would be relevant to the project are included in SCC 21.16.070(A)(1) and are listed and analyzed below.

1. Be either compatible with other uses in the surrounding area or is no more incompatible than are other outright permitted uses in the applicable zoning district;
Response: The project site and the site proposed for the alternative Operations and Maintenance facility along West Pit Road are used for commercial timber operations and construction characterized by regular timber management activities, including timber cutting and heavy equipment usage. The project site has been harvested for many years, based on established harvest schedules using an approximate 50-year rotation. In the surrounding area, between Underwood Mountain and the Little White Salmon River, the predominant land use is commercial forest production. Immediately east of the Little White Salmon River, there is some land zoned Residential (R-2, R-5, and R-10). However, most of this land is currently being used for commercial timber production and is owned by S.D.S. Co., LLC, Broughton Lumber Company, or WDNR. Only one 40-acre parcel adjacent to the east project boundary is owned by a private individual not involved in the project. This parcel is in commercial forest production and contains no residential structures.

The proposed turbine corridor A1-A7 would be subject to a conditional use permit. The nearest residence outside the National Scenic Area, on lands zoned R-2, R-5 or R-10, is located at least 0.5 mile from this proposed corridor (Figure 4.1-1, Noise Level Contours). The rural communities of Mill A and Willard are located west of the Little White Salmon River. Mill A is approximately 1.5 miles from proposed turbine corridor A1-A7 and Willard is approximately 2.25 miles north.

The proposed alternative site along West Pit Road for the Operations and Maintenance facility would also be subject to a conditional use permit. The nearest residence is located along Young Road, approximately 0.25 mile from the facility site (Figure 4.1-1, Noise Level Contours).

The project has been designed to be compatible with commercial forest use. For example, some turbines are proposed on ridgelines, existing private forest roads would be used for access, and forest rotation schedules and tree heights have been considered so that the design life of the project would be compatible with the growth rate of the trees in surrounding forest blocks. The Applicant has established a replanting and timber management profile to provide the maximum ongoing use of the project site for commercial forestry operations, minimizing the need for permanent or temporary conversion to non-forestry uses (Figure 2.3-2, Forest Management).

The project would help diversify the income potential for the landowner while minimizing conversion of timber lands to other uses. The project site and vicinity are within an existing utility corridor already characterized by massive electrical transmission facilities operated by BPA, a natural gas pipeline, two cellular communication towers, and rock pits for forest operations. There are large lattice electrical towers and four high-voltage transmission lines crossing turbine strings A and B (Figure 2.1-1, Location of Proposed Whistling Ridge Energy Project). Allowable administrative and conditional uses that would be permitted within the R-10 and For/Ag-20 zones are shown in Table 4.2-2. These uses are subject to standards in the R-10 and For/Ag-20 zones according to SCC 21.4036.050 and SCC 21.56.050, respectively, as well as code sections specified for particular listed uses.

Standards in SCC 21.4036.050 and 21.56.050 include limitations as to lot size, density, and setbacks; a 35-foot building height limit; off-street parking requirements; and prohibition of building location within easements. In the R-40-5 zone, minimum lots size is 40-5 acres with a
maximum density of one single family dwelling unit per 40-5 acres. Setbacks in this zone are as follows:

- Front Yard: 50 feet from the centerline of the public road right of way or 34-35 feet from the centerline of a private road, or 20 feet from the front property line, whichever is greater
- Side Yard: 20 feet from all side property lines
- Rear Yard: 20 feet from the rear property line

In the For/Ag-20 zone, minimum lot size is 20 acres with each single-family dwelling unit requiring at least an acreage amount equal to the required minimum lot size. Setbacks in this zone are as follows:

- Front Yard: Same as R-40-5 zone
- Side Yard: 25 feet from all side property lines
- Rear Yard: 25 feet from all rear property lines

As proposed, the project would meet all these requirements.

Washington’s Forest Practices Act allows timber harvest and surface mining as part of commercial forest practices. The turbine corridor proposed within the For/AG-20 and R-10 zones would be visible from Mill A and Willard. However, they are no more incompatible with the surrounding area than other uses permitted in the County’s zoning code (Table 4.2-2) and by Washington’s Forest Practices Act. The project would in no way impair the use of any of the surrounding lands in accordance with applicable zoning codes and land use plans. The wind turbine generators also would be compatible with the other major electrical and communications systems already present in the project vicinity. Information contained in this Application, and the EIS to be prepared for the project, will fully consider the potential project impacts including visual impacts, noise, and impacts to wildlife.

b. Not materially endanger the health, safety, and welfare of the surrounding community to an extent greater than that associated with other permitted uses in the applicable zoning district;

Response: A Geotechnical Report has been prepared to analyze existing soil and subsurface conditions and to determine the appropriate foundation design (see Section 3.1 and Appendix A). Turbines are designed to meet industry standards in all wind conditions, including shutting down during certain wind conditions. The wind turbine corridors are proposed at a minimum distance of, 4,265 feet (0.8 mile) from any residences on R-2, R-5 or R-10 lands, and 2,000 to 2,560 feet (0.38–0.48 mile) from the nearest residence in the Scenic Area (Figure 4.1-1, Noise Level Contours).
Vegetation clearing around each proposed turbine corridor would allow for safe construction, and would reduce the potential for growing trees to interfere with the wind resource on the site during the commercial life of the project (at least 30 years). Typically, a permanently cleared area would extend 50 feet in all directions from each turbine. Between 50 feet and 150 feet from the base of the turbines, tree heights would be limited to 15 feet above the turbine base elevation. Extending from 150 feet to 500 feet from the base of the turbines, a tree-height restriction of 50 feet in height would be maintained for trees located within an area formed by a 90 degree angle centered on the prevailing wind direction (Figure 2.3-4, Turbine Timber Buffer).

In addition to the clearing around turbines, there would be a 50-vertical-foot limitation placed on trees along any overhead electrical cable corridors, or such other height as may be required by BPA. Where underground cables are not installed along existing roads, no trees would be planted within 5 feet from the centerline of the cable trenches.

Improvements to forest roads for construction and access would provide improved access for fire and other emergency response vehicles in an emergency situation. As documented in Section 4.1.1 Noise, the project would comply with Washington’s applicable noise standards. As discussed in that Section and in Section 4.2.2 Light and Glare, no glare impacts are anticipated.

c. **Not cause the pedestrian and vehicular traffic associated with the use to conflict with existing and anticipated traffic in the neighborhood to an extent greater than that associated with other permitted uses in the applicable zoning district;**

Response: Access to the project area is provided via County roads that extend north from SR 14. From SR 14, access is provided via County roads (Cook-Underwood Road to Kollock-Willard Road onto Scoggins Road) and via a new connection to West Pit Road, an network of existing private logging roads. The private logging roads are West Pit Road is on S.D.S. Co., LLC and Broughton Lumber Company property, and would provide access to most areas where project facilities are proposed.

Constructing the project would require 2.4 miles of new construction and 5.4 miles of improvements to existing private logging roads outside the Scenic Area. All these improved and constructed roads would continue to be used during the project’s operational phase.

Within the project area and its access roads, both pedestrian use and traffic volumes are currently very low, and would remain so during project construction and operation. During the 12-month construction period, an average of 143 workers would be employed. Peak work force would be 330 workers. Labor and equipment access would be via existing logging roads. Because the project is proposed on land that would remain in the commercial forest operator’s ownership, the use of private forest roads for project construction would be easily coordinated to minimize impacts to forest operations.

When the project is operational, eight to nine permanent full-time and/or part-time employees are proposed as Operations and Maintenance staff. This number is similar to, or less than, staff numbers currently involved in on-going timber management.
Further information regarding the transportation impacts of the project is presented in Section 4.3 Transportation.

d. Be supported by adequate service facilities and would not adversely affect public services to the surrounding area;

Response: The construction period is anticipated to last 12 months and employ up to 330 workers. Not all workers would be on site during the same period. The work force at the site would average 143 workers per day, and peak at 265 workers. Because of the site’s commuting proximity to the Vancouver, Washington and Portland, Oregon labor pools, it is not anticipated that there would much of a demand for temporary housing or school enrollment in the immediately-surrounding communities (Section 4.4, Socioeconomics). The construction management plan would include provisions for site security and on-site initial emergency response (see Section 2.16). Whistling Ridge Energy LLC would negotiate with existing service providers to ensure there would be adequate response from potential emergency service needs during the construction period.

A well and on-site septic system would be installed to provide potable water for the Operations and Maintenance facilities. The anticipated demand for fire and police services is estimated to be low, and similar to other commercial operations in the project vicinity (Section 4.4 Socioeconomics).

e. Not hinder or discourage the development of permitted uses on neighboring properties in the applicable zoning district as a result of the location, size or height of the buildings, structures, walls, or required fences or screening vegetation to a greater extent than other permitted uses in the applicable zoning district;

Response: All property immediately east of the project is owned by the Applicant and is in the UNM zone. There are no neighboring off-project properties located within the For/Ag-20 zone. Adjacent off-project lands to the north are located in Klickitat County and are under State ownership, managed by WDNR for timber production.

There are seven properties adjacent to the west project boundary that are zoned R-10. Of these, only three are owned by a person or entity other than the Applicant. Two are owned by the State and managed by WDNR, and one totaling 40 acres is in private ownership. All these neighboring properties are managed as commercial forest land with no residential structures. The nearest residence to the alternative Operations and Maintenance facility site is approximately 0.25 mile away. It is located in an area zoned R-10.

There are five adjacent off-project properties to the south located within the Scenic Area. These are primarily zoned GMA large-scale agricultural (GMA Ag-1) or commercial forest (GMA F-1). Of these five properties, only one totaling 29 acres is owned by someone other than the Applicant. The 29-acre parcel is primarily managed as forest and orchard lands with 1 acre used for residential purposes. The owners of this property have been vocal opponents of the proposed wind energy facility. They submitted a Scenic Area application, and received approval from Skamania County, to re-locate their existing home to within 50 feet of their north property line. This new location would bring the residence to within 2,000 feet of the closest proposed turbine
corridor. Except for this parcel, all adjacent lands to the south are in commercial timber production.

Approximately seven turbines are proposed within the For/Ag-20 zone, and approximately four are proposed in the R-10 zone (those that require a conditional use permit). These turbines proposed in corridor A1-A7 would be in a somewhat isolated part of the For/Ag-20 and R-10 zones. Washington’s Forest Practices Act allows timber harvest and surface mining as part of commercial forest practices. Other uses permitted within the R-10 and For/Ag-20 zones are listed in Table 4.2-2.

The turbines in the corridor proposed in the R-10 and For/Ag-20 zones would be approximately 426 feet tall (measured to the blade tip). Their height and visibility would not hinder or discourage the development of any of the uses identified in Table 4.2-2. Impacts related to commercial resource production and harvesting are considered part of the existing working landscape. The proposed turbines would be taller than other structures permitted outright in the For/Ag-20 zone; however, they would be considerably quieter than other uses allowed in the zone, such as some forestry or surface mining operations. Except for areas to be cleared for the proposed project, regular timber harvest would continue within the project site.

Neighboring forest lands are subject to regular harvest, which is generally accomplished through clear cutting. After timber harvest, areas not converted to a non-forestry use must be re-planted within a time frame specified in Washington Forest Practices rules. Project retirement is likely to coincide with the regular harvest cycle on the project property. The project would in no way hinder the use or development of surrounding properties in accordance with existing land use planning and zoning. Further, the project would create an additional revenue stream for the Applicant, which would encourage continued use of the site for commercial timber harvest. Thus, the owner would be better able to weather timber industry economic down-cycles, and the project would create disincentives for potential conversion to other uses such as residential.

\[ f. \quad \text{Not be in conflict with the goals and policies expressed in the current version of the County’s comprehensive plan.} \]

Response: See above for a detailed discussion of the project’s relationship to, compliance with, Skamania County’s 2007 Comprehensive Plan.

Skamania County Code, Title 21A, Critical Areas

Title 21A only applies outside the Scenic Area. It regulates development in areas identified by the Washington State Legislature in RCW 36.70A.060 as being critical to the ongoing health of the state’s natural and built environment. These critical areas include:

- Wetlands
- Areas with a critical recharging effect on aquifers used for potable water
- Fish and wildlife habitat conservation areas
• Frequently flooded areas
• Geologically hazardous areas
• Ponds and lakes
• Streams, creeks, and rivers

The project is not located within any critical recharge areas, frequently flooded areas, ponds and lakes, or rivers. Portions of the project site would be located near geologically hazardous steep slopes classified as Class II and III Landslide Hazard Areas (See Section 2.15 for a detailed discussion of hazards). There are wetlands, fish and wildlife habitat conservation areas, streams, and creeks on the site.

No new construction would occur within wetlands, streams, or their buffers. The proposed access road, West Pit Road, crosses one unnamed drainage in the Lapham Creek watershed. This stream had observed flow through the existing culvert under West Pit Road at the time of the July 2009 field visit. However, the surface flow and the channel disappear downstream of the culvert. The planned improvements to existing roads that would occur inside the Scenic Area would cross one stream (shown on Figure 3.3-1 Waterways in the Project Vicinity). This stream has no defined channel and carries water only during runoff events downstream of the culvert. It is classified as a Class V stream under SCC 21A.04.020(B) Appendix C. Buffers are established for Class V streams. However, expansion of existing uses is allowed within these water resource buffers. Development review would be required under SCC 21A.05 and SCC 21A.06 in Fish and Wildlife Protection Areas and Geologically Hazardous Areas in consultation with WDFW. However, existing roadways would be allowed without review so long as any expansion is 100% or less of the original footprint. The road improvements in these regulated fish and wildlife protection areas do not exceed the allowed expansion threshold. For a full discussion of fish, wildlife, their habitats, and project impacts to these, please see Section 3.4 Habitat, Vegetation, Fish and Wildlife.

In a letter to EFSEC, dated May 4, 2009, Karen Witherspoon, Skamania County Community Development Department Director, found that the proposed project is consistent with SCC Title 21A Critical Areas. A similar letter will be requested of the County to address the new access road and the alternative location for the Operations and Maintenance facility.

4.2.1.3 Relationship of Project Site Access Route to Existing Land Use Plans and Policies

Skamania County Code, Title 22, Columbia River Gorge National Scenic Area

The Project is proposed adjacent to the Scenic Area. Access to the site would be through the Scenic Area. The National Scenic Area Act expressly states: “Nothing in Sections 544 to 544p of this title shall *** establish protective perimeters or buffer zones around the scenic area or

1 The wetland on the project site results from a constructed impoundment according to National Wetland Inventory maps and so is not regulated locally as a critical area according to SCC Title 21A.04.020(A)(1)(b).
The fact that activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas (16 USC § 544(o) Section 17(a)(10)).” Thus, siting the project up to the Scenic Area boundary is acceptable under the Act as approved by the United States Congress.

The Scenic Area is comprised of three land use classifications: GMA, SMA, and Urban Areas. SMAs, which contain the most sensitive resources, are managed by the US Forest Service. GMAs include a mixture of historic land uses such as farming, logging, residential, and cattle grazing. Development on GMA lands is administered by five of the six Gorge Counties and the Columbia River Gorge Commission. Both SMAs and GMAs are subject to local Scenic Area codes deemed consistent with the Scenic Area Management Plan by the Columbia River Gorge Commission and the US Secretary of Agriculture prior to adoption. In Skamania County, Scenic Area development regulations are codified in SCC Title 22. Urban Areas (including Cascade Locks, Hood River, Mosier, and The Dalles in Oregon, and North Bonneville, Stevenson, Carson, Home Valley, White Salmon, Bingen, Lyle, Dallesport, and Wishram in Washington) are exempt from Title 22 Scenic Area regulations.

The Act has two purposes (16 USC § 544(a) Section 3):

1. “To establish a national scenic area to protect and provide for the enhancement of the scenic, cultural, recreational, and natural resources of the Columbia River Gorge; and

2. To protect and support the economy of the Columbia River Gorge area by encouraging growth to occur in existing urban areas and by allowing future economic development in a manner that is consistent with paragraph (1), the Act’s first purpose.”

The project would be located entirely outside the Scenic Area, not just in an exempt Urban Area. As a result, the project itself would not conflict with the Act’s first purpose of protecting scenic, cultural, recreational, and natural resources in the Scenic Area.

Improvements to 2.1 miles of private road (CG2930) would be required to access the project. This road crosses lands that are in the GMA but outside the project boundary. These lands are zoned large-scale agriculture (GMA A-1) and commercial forest (GMA F-1). Improvement of the existing access road CG 2390 through the Scenic Area would fulfill the Act’s second purpose by supporting the Columbia River Gorge economy in areas exempt from Scenic Area regulations. Further, the road improvements within the Scenic Area would be designed to comply with applicable provisions of SCC Title 22.

As indicated in Section 4.3 Transportation, the proposed CG2930 private road improvements would require a haul route agreement and negotiated road approach permit. These also would cover required improvements to four existing County right-of-way intersections in the Scenic Area GMA, which are described in detail in Section 4.3. Intersection improvements would be subject to review under Title 22.
GMA Ag-1 and F-1 Standards

The GMA Ag-1 zone does not impose further restrictions on road construction, reconstruction and modification (SCC 22.14.010). However, fire safety provisions (22.14.030(A)) and siting criteria (22.14.030(B)) apply to this review use in the GMA F-1 zone (SCC 22.14.030[E][1][b]).

Scenic-Resource Protection Standards

GMA scenic resource protection provisions require the Administrator to make “a determination of compatibility with the landscape setting based upon information submitted in the site plan (SCC 22.18.020[A][4]).” Landscape settings in the Scenic Area are “designated on a map entitled ‘Landscape Settings’ adopted on October 15, 1991” as part of the Management Plan for the Columbia River Gorge National Scenic Area (Management Plan) (SCC 22.18.040[A]). According to the Landscape Settings map, the proposed road improvements are located in the Coniferous Woodland landscape setting, which is governed by standards in SCC 22.18.040(C).

Additional scenic resource standards apply to new developments topographically visible from key viewing areas (KVAs) SCC 2.18.030. The Management Plan designates “important public roads, parks, and other vantage points providing public scenic viewing opportunities” as KVAs (GMA Policies Part I-1-6). Designated KVAs are listed in the Management Plan’s glossary of terms (Glossary 11). The proposed road improvements would be potentially visible from the KVAs listed in Table 4.2-3.

Table 4.2-3
KVA Locations from Which the Road Improvement Area is Likely Visible

<table>
<thead>
<tr>
<th>KVA</th>
<th>Length of KVA Segment from which Road CG2930 is Visible</th>
<th>Length of CG2930 Segment Visible from KVA</th>
</tr>
</thead>
<tbody>
<tr>
<td>I-84, including rest stops</td>
<td>1.11 miles</td>
<td>236 ft</td>
</tr>
<tr>
<td>SR-14</td>
<td>1,333 ft</td>
<td>571 ft</td>
</tr>
<tr>
<td>Panorama Point Park</td>

<td>3,051 feet total from 3 segments of 1,256 feet, 1,144 feet, and 651 feet, respectively, from east to west</td>
<td>4.64</td>
</tr>
</tbody>
</table>

If a subject site is topographically visible from any KVA (see Figure 4.2-27, Key Viewing Areas and Recreational Facilities Within Approximately 25 Miles of the Site in Section 4.2.4.1), the Administrator would make findings of factors influencing potential visual impact (SCC 22.18.030[C][1]) and may apply conditions pertaining to siting, retention of existing vegetation, design, and new landscaping (SCC 22.18.030(C)(2) according to SCC 22.18.030(E) through SCC 22.18.030(I)).
Existing vegetation would be retained to the maximum extent practicable along improved Scenic Area roadways, and any disturbed areas would be re-vegetated to maximize vegetative screening of the site from KVAs where topographic screening is not possible. It is likely that most, if not all, of the proposed road improvements would be fully screened from KVAs by a combination of existing and planted vegetation and topographic screening. Visual impacts are discussed in detail in Section 4.2.3.

**Natural Resource Protection Standards**

SCC 22.20.010 requires evaluation of all uses against the Practicable Alternatives Test, which is satisfied by the alternatives analysis in Section 2.19. Natural resource protection provisions in SCC 22.20 apply to all uses “in a water resource or its buffer” (22.20.020), review uses “within 1,000 feet of a sensitive wildlife area or site” (SCC 22.20.030), and review uses “within 1,000 feet of a sensitive plant” (SCC 22.20.040). Figure 3.3-1 Waterways in the Project Vicinity shows all water resources in the vicinity of the proposed Scenic Area road improvements. Figures included in Section 3.4 show sensitive wildlife areas and sites, and sensitive plants. The project crosses one water resource zone, but does not lie within 1,000 feet of sensitive wildlife areas or sites, or sensitive plants. SCC 22.20.020 applies, but SCC 22.20.030 through SCC 22.20.040 do not.

The existing CG2930 road in the Scenic Area crosses one seasonal stream located roughly in the middle of its length (Figure 3.3-1 Waterways in the Project Vicinity). This stream does not support any resident or anadromous fish species (Section 3.4). Expansion of existing roadways is allowed within water resource zones or their buffers so long as the Practicable Alternatives Test is satisfied and the proposed expansion does not exceed 100% of the original footprint or encroach further on the water resource or its buffer.

**Cultural Resource Protection Standards**

SCC 22.20 contains standards for cultural resource protection. According to SCC 22.20.010(A), all cultural resource information is confidential and exempt from public records requests according to § 6(a)(1)(A) of the Act. Cultural reconnaissance surveys are required and have been performed (see Section 4.2.5). All proposed uses must follow SCC 22.22.060 “when cultural resources are discovered during construction activities” and SCC 22.22.070 “when human remains are discovered during a cultural resource survey or during construction.” These standards would be followed in the event of any such discovery.

**Recreational Resource Protection Standards**

SCC 22.24 applies only to resource-based recreation uses, development, and facilities. The proposed road improvements are not associated with any recreation uses, developments or facilities whether resource-based or not. Hence, SCC 22.24 does not apply.
4.2.1.4.2.1.3 Relationship of State of Washington to Existing Land Use Policies and Plans

At the option of the Applicant, the siting of energy facilities such as Whistling Ridge Energy Project is regulated at the state level by EFSEC, under Chapter 80.50 RCW (Energy Facilities - Site Locations) and Title 463 WAC. Applicants for certification from EFSEC are required to submit detailed information on the proposed development and the impacts the development may have on the natural and built environments. The applicant is also required to describe the means to be utilized to minimize or mitigate possible adverse impacts on the physical or human environment (WAC 463-60-085). Further, the applicant is required to set forth insurance, bonding, or other arrangements proposed in order to mitigate for damage or loss to the environment (WAC 463-60-075). Whistling Ridge Energy LLC has requested the jurisdiction of EFSEC for the project.

Chapter 80.50 RCW operates to preempt all state and local matters relating to energy facility sites that are under the jurisdiction of EFSEC. Certification pursuant to Chapter 80.50 RCW is given in lieu of any permit, certificate, or similar document that might otherwise be required. Procedures to be followed by EFSEC in determining whether or not to recommend that the state pre-empt local land use plans or zoning ordinances for a site or portions of a site for an energy facility are set forth in WAC 463-28. In a letter to EFSEC, dated May 4, 2009, Karen Witherspoon, Skamania County Community Development Department Director, found that the proposed project is consistent with SCC Title 21 Zoning Code, SCC 21A Critical Areas, Title 24 Clearing and Grading, the Comprehensive Plan, and resource maps. The Applicant anticipates that the project would be consistent with applicable local land use plans, zoning ordinances, and other local development regulations. A similar letter will be requested from the County addressing the West Pit Road for project access and the alternative location for the Operations and Maintenance facility. To the extent the application may be inconsistent with local land use plans, zoning ordinances, and other local development regulations, the Council has the statutory authority to recommend that the Governor exercise preemption. The Applicant does not anticipate such action in these proceedings.

4.2.1.54.2.1.4 Mitigation Measures

No impacts to land use are anticipated, and no mitigation measures are required.

See Sections 2.15 Protection from Natural Hazards, 3.2 Air Quality, 3.3 Water, and 3.6 Energy and Natural Resources for a description of the measures included in the project design to ensure the proper management of the natural environment.
See Sections 2.7 Characteristics of Aquatic Discharge Systems, 2.15 Protection from Natural Hazards, 3.3 Water, 3.4 Habitat, Vegetation, Fish and Wildlife, and 3.5 Wetlands for a description of the measures included in the project design to enhance water quality and protect environmentally sensitive areas.

See Sections 2.15 Protection from Natural Hazards and 3.1 Earth for a description of the measures included in the project design to minimize the loss of life and property from landslides, seismic, volcanic, or other naturally occurring events, and minimize or eliminate land use impacts on geologically hazardous areas.

See Sections 3.3 Water, 3.4 Habitat, Vegetation, Fish and Wildlife, and 3.5 Wetlands for a description of the measures included in the project design to protect fish and wildlife habitats.

4.2.2 LIGHT AND GLARE

4.2.2.1 Existing Environment

Ambient Light Levels

At present, the project site and surrounding area are relatively dark at night with low levels of ambient lighting. Primary light sources are from the small residential areas nearby and ambient light from cities and towns and industry along the Columbia River Gorge. The major sources of light come from outdoor lights at the residential properties and headlights on the surrounding roads. These are considered minor light sources because of their low density.

Glare

Currently no reflective objects or facilities exist in the project area that could provide a source for glare. Occasional timber harvest activities such as truck movement and potential helicopter harvest could be considered a source for glare. Beyond these activities no other manufactured sources of glare exist within the project area.

Shadow Flicker

The existing changes in light intensity in the project area consist of movement of the sun through the trees and other vertical land forms. This light reflects and changes in intensity as the sun moves to differing quadrants, which are seasonally different and are considered slow in movement and intensity. Beyond these changes in light intensity from natural sources, no shadow flicker exists in the area.

4.2.2.2 Impacts to Ambient Light Levels

Construction

Most construction would occur during daylight hours; however, minimal lighting would be used on the site at night for safety purposes. Impacts would be negligible or minimal and construction or short-term related.
Operation

In response to the FAA aviation safety lighting requirements, the wind turbines must be marked with lights for nighttime lighting. Under recently released guidelines, the FAA no longer requires daytime lighting of the turbines if the turbines are painted a non-reflective flat neutral gray or light color. Whistling Ridge Energy LLC is proposing to paint the turbines a non-reflective flat neutral gray or light color, and is not proposing to install white daytime aviation warning lights unless required by FAA as part of the No Hazard Determination.

Nighttime lighting would be limited to the minimum allowed by the FAA, which would likely consist of two lights on the first and last turbine of every string, and two lights on turbines located every 1,000 to 1,400 feet between the ends of the strings (Patterson 2005). The number of red nighttime aviation warning lights would consist of approximately 24 lights based on these parameters. The flashing red lights would add a new visual element into the project area’s nighttime landscape. The flashing red lights would be most noticeable within one mile of the project and would be visible at night from residential properties in these areas, including some residents on or near the hillside east of the site, and some residents across the Columbia River in Oregon.

Other project facilities that would require outdoor lighting at night for operational safety and security include the proposed Operations and Maintenance facility and substations. These facilities would create sources of light in areas where there is no nighttime lighting other than vehicle headlights and would contribute to the overall increase of nighttime illumination in the project area. Sensors and switches would be used to keep lights turned off when lighting would not be required. All lights would be hooded and directed to minimize backscatter and illumination of areas outside the Operations and Maintenance area and the substation sites.

The facility is expected to make a slight contribution to overall ambient light levels in the immediate vicinity, which would constitute a minimal change to residents within one mile of the site.

4.2.2.3 Impacts from Glare

Construction

Most construction would occur during daylight hours, minimizing construction lighting at during hours of darkness. With the proposed daytime construction hours, and the relative remoteness of the project site, glare impacts during construction are not anticipated.

Operation

As a safety requirement, the Operations and Maintenance building would be illuminated at night. Because the building is located away from commercial or residential development, and there are few neighboring properties, light and glare impacts on are expected to be negligible.

During the day, potential glare impacts would be minimal because of the planned use of non-reflective earth-tone/light paint colors on exterior building or facility surfaces. There would be
no anticipated glare impacts to vehicular drivers using I-84, SR 141, SR 14, or local access roads.

Proposed mitigation measures are outlined in Section 4.2.2.5. These measures include restricting lighting at the Operations and Maintenance facilities and substation to the minimal required lighting, and assuring that all lighting is appropriately hooded and directed downward into the areas where it is needed. With these measures in place, the potential for the buildings to create skyglow or backscatter would be limited and considered a negligible impact.

4.2.2.4 Impacts from Shadow Flicker

Construction

No shadow flicker impacts are expected to occur during construction.

Operation

Shadow flicker caused by wind turbines is defined as alternating changes in light intensity as the moving blade casts shadows on the ground and objects (including windows at residences). Analyses previously conducted at other wind energy facilities approved by EFSEC (Kittitas Valley Wind Power Project and the Wild Horse Wind Power Project) examined the potential effects of shadow flicker for residents near the proposed projects and recommended certain measures for minimizing these effects. However, due to the significant distance of the project to residences, shadow flicker is not anticipated to be noticeable for this project.

Shadow flicker, or strobe imparts, can only occur if the location of the turbine is close to a receptor that is in a position where the blades interfere with very low-angle sunlight. As the Council found in the Kittitas Valley Wind Power Project, as the distance between the wind turbine generators and residences increases, the perception of shadow flicker decreases or attenuates. The impact of shadow flicker at a particular residence depends on the location of the residence and the position of features of the home (e.g., windows) in relation to the wind turbines. At a distance beyond 2,500 feet, shadow flicker is considered to be imperceptible. The project is not expected to result in any shadow flicker effects due to the distance of more than 2,500 feet to the nearest existing residence (Figure 4.1-1 Noise Level Contours shows locations of closest residences.) This distance is beyond the distance of which shadow flicker can cause an impact. Moreover, the topography of the project site in relation to the existing residences, orientation of residences, and the tree cover between residences and the wind turbine generators are expected to further eliminate any risk of perception of shadow flicker. Even if shadow flicker were a proven impact (as the Council found in the Kittitas Valley Wind Power Project case) for proven significant impacts, operational controls can be implemented to completely eliminate this perceived impact.
4.2.2.5 Mitigation Measures

Mitigation measures for light and glare would be as follows:

- Most construction would occur during daylight hours, minimizing construction lighting at during hours of darkness
- Turbines and blades would be painted with a non-reflective gray finish to blend in with the background, and to eliminate the need for white daytime aviation warning lights
- To prevent glare, non-reflective earth-tone/light paint colors would be used on exterior surfaces of buildings or other facilities
- The facility lights outside the Operations and Maintenance area and the substation sites would be hooded and directed downward to minimize backscatter and illumination of off-site areas
- Lights would be the minimum wattage required for safety
- Sensors and switches would be used to keep lights turned off when lighting is not required

See Section 4.2.3.4 for a discussion of recommended mitigation measures for visual impacts.

4.2.3 AESTHETICS

This section describes the existing visual environment in and around the project area. It assesses the potential for visual impacts using accepted methods of evaluating visual landscape quality and predicts the type and degree of changes the project would likely have on the sensitivity of those attributes. Additionally, this project would incorporate previous project lessons and experience including design principles and the latest aesthetic design refinements. This section also identifies mitigation measures designed to minimize those impacts.

Each landscape has a specific quality that gives a geographic area its visual and cultural image, and consists of the combination of physical, biological, and cultural attributes that make each landscape identifiable or unique. An existing landscape character may range from a predominantly natural landscape to landscapes that are heavily culturally influenced. The existing scenic quality of an existing landscape includes the natural scenic attributes of the landscape in combination with the existing land use patterns. The list of attributes includes naturally evolving, natural appearing, pastoral, agricultural, or even urban landscapes and generally are at the broadscape or landscape level of the analysis but can be analyzed for each specific viewpoint at a project level.

The sensitivity of a landscape or view of that landscape is based on the scenic integrity of the landscape and the types of viewers. A landscape that has a high degree of integrity is a landscape that has a sense of wholeness, intactness, or being complete. Its scenic quality is near-
perfect, with no evident discordant elements or deviations from the existing character, making it highly sensitive to most changes and to the perceptions of the viewer types.

The consideration of the alteration of the landscape by the introduction of wind turbines, and the visual impacts of wind turbines on the landscape is a complex issue, and factors other than the attributes described above play a major role in the observer’s reaction or perception of the visual impacts or change. Moreover, in an era when Washington and the United States are mobilizing to address the perils of climate change, the aesthetic impacts of renewable energy raises critical policy issues of statewide and national significance.

Surveys have been taken of viewers of existing wind projects. The findings showed that some viewers had a positive reaction in that they saw wind projects as a progressive step in fighting climate change. Those who had a negative reaction were more concerned with the localized perceived visual “clutter” and “unattractiveness” of the facilities on any landscape (Thayer and Freeman 1987). Understanding the types of viewers in, around, and through the project area is important in making sure that these types of perceptions are considered in the visual sensitivity assessment for this project. This analysis establishes an analytical framework and data for evaluation of the Application. It does not come to the conclusions of environmental impact or the balancing of environmental and policy considerations that are inherent in the SEPA process. How these perceptions and impacts are addressed and balanced against competing policy issues is ultimately an issue for the Siting Council and the Governor.

4.2.3.1 Methodology

The visual impact assessment used the Scenery Management System defined in Landscape Aesthetics, A Handbook for Scenery Management (USFS 1995) and Visual Impact Assessment for Highway Projects (FHWA 1988). The study is also designed to respond to the provisions of WAC 463-42-362, Built Environment – Land and Shoreline Use, which specify the analysis of aesthetic and light and glare issues as part of the EFSEC process.

The analysis of the visual effects of changes that might occur with implementation of the proposed wind energy facility is based on field observations and review of wind energy facilities visual effects, public perception, design measures to reduce visual impacts, and local planning documents. Additionally, project maps, drawings, technical data, and computer generated maps provide an assessment of areas where the project would be visible and generated visual simulations representing the contrast from the existing conditions if the project is implemented. The analysis includes systematic documentation of the visual setting, evaluation of visual changes associated, and measures designed to mitigate the visual effects. These measures include restoration or enhancement activities to areas that have been disturbed during construction.

Scenic Quality Assessment

To assess the scenic quality of the landscapes potentially affected by the proposed project, the analyses of views toward the project site from selected viewpoints includes an overall rating of the scenic quality prevailing in the existing views. Scenic quality ratings were developed based on observations in the field, photographs of the affected area, methods for assessment of visual
quality, and research on public perceptions of the environment and scenic quality ratings of landscape scenes. The final assessment of scenic quality was made based on professional judgment that took a broad spectrum of factors into consideration, including:

- Natural features, including topography, watercourses, rock outcrops, and vegetation
- The positive and negative effects of human alterations and built structures on visual quality
- Visual composition, including an assessment of the vividness, intactness, and unity of patterns in the landscape, defined as follows:
  - Vividness refers to the memorability of the visual impression received by the viewer from contrasting landscape elements as they combine to form a striking and distinctive visual pattern
  - Intactness is the integrity of visual order in the natural and human landscape, and the extent to which the landscape is free from visual encroachment
  - Unity is the degree to which the visual resources of the landscape join together to form a coherent and harmonious visual pattern

Each viewpoint was assigned a final rating based on the rating scale shown in Table 4.2-4. This rating scale incorporates landscape assessment concepts developed by USFS and U.S. Department of Transportation.

<table>
<thead>
<tr>
<th>Rating</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Outstanding Visual Quality 6</td>
<td>A rating reserved for landscapes with exceptionally high visual quality. These landscapes are significant nationally or regionally. They usually contain exceptional natural or cultural features that contribute to this rating. They are what we think of as “picture postcard” landscapes. People are attracted to these landscapes to view them.</td>
</tr>
<tr>
<td>High Visual Quality 5</td>
<td>Landscapes that have high quality scenic value. This may be due to cultural or natural features contained in the landscape or to the arrangement of spaces contained in the landscape that causes the landscape to be visually interesting or a particularly comfortable place for people. These landscapes have high levels of vividness, unity, and intactness.</td>
</tr>
<tr>
<td>Moderately High Visual Quality 4</td>
<td>Landscapes that have above average scenic value but are not of high scenic value. The scenic value of these landscapes may be due to human or natural features contained within the landscape, to the arrangement of spaces in the landscape, or to the two-dimensional attributes of the landscape. Levels of vividness, unity, and intactness are moderate to high.</td>
</tr>
<tr>
<td>Moderate Visual Quality 3</td>
<td>Landscapes that are common or typical landscapes with average scenic value. They usually lack significant human or natural features. Their scenic value primarily results from the arrangement of spaces contained in the landscape and the two-dimensional visual attributes of the landscape. Levels of vividness, unity, and intactness are average.</td>
</tr>
<tr>
<td>Moderately Low Visual Quality 2</td>
<td>Landscapes that have below average scenic value but not low scenic value. They may contain visually discordant human alterations, but these features do not dominate the landscape. They often lack spaces that people perceive as inviting and provide little interest in terms of two-dimensional visual attributes of the landscape.</td>
</tr>
<tr>
<td>Low Visual Quality 1</td>
<td>Landscapes that have below average scenic value. They may contain visually discordant human alterations, and often provide little interest in terms of two-dimensional visual attributes of the landscape. Levels of vividness, unity, and intactness are below average.</td>
</tr>
</tbody>
</table>

Visual Sensitivity Assessment

Assessing visual sensitivity involves predicting the general impact on the quality of views from a given viewpoint. A combination of three factors determines how sensitive a landscape scene is:

- The number and type of viewers
- The viewing conditions
- The quality of the view

Residential areas with unobstructed views of a regionally important and memorable scene would be very sensitive to objects or structures that would impede views. A view from a seldom-traveled rural road where motorists have only distant, oblique views of wind turbines in an unremarkable setting would likely qualify as an area of low sensitivity.

The principal types of viewers in the project area who have predictably high levels of sensitivity to visual impacts include:

- Resident viewers
- Roadway viewers (drivers and passengers)
- Recreating viewers such as hikers, water recreationists, and mountain bikers

This analysis of visual sensitivity defines three levels as follows:

- **Low 1.** Viewer types representing low visual sensitivity include agricultural and industrial/warehouse workers. Compared with other viewer types, the number of viewers is generally considered small and the duration of view is short. Low levels of sensitivity are assigned to areas 5 miles or more from the closest turbine, where a wind power project would be a distant and a relatively minor element in the overall landscape.

- **Moderate 2.** Viewer types representing moderate visual sensitivity consist of highway and local travelers. The number of viewers varies depending on location; however, on average they tend to be moderately large, based on overall densities of surrounding areas and highway commuters. Viewer awareness and sensitivity are also considered moderate because destination travelers often have a focused orientation. Moderate levels of sensitivity were assigned to areas where turbines would be visible from 0.5 mile to 5 miles within the primary view of residences and roadways. The primary view refers to the central area that the eye can see clearly without moving and is surrounded by the peripheral vision. In distinguishing between moderate and low levels of sensitivity in the 0.5-mile to 5-mile zone, contextual factors were also considered, including the viewing conditions in the immediate foreground of the view.
• **High 3.** Residential, recreational, and viewers congregating in public gathering places (churches, schools, trails, etc.) are considered to have comparatively high visual sensitivity. The visual setting may in part contribute to the enjoyment of the experience. Views may be of long duration and high frequency. High levels of sensitivity are generally assigned in those cases where turbines would be potentially visible within 0.5 mile or less from residential properties, heavily traveled roadways, or heavily used recreational facilities.

These criteria were used to establish the sensitivity levels of each view using a systematic approach based on the distance of the project from the viewpoint, the number of turbines or percentage of the project area that could be viewed from this viewpoint, and the dominant viewer types for each view. Through this process, an overall sensitivity rating was established for each existing landscape view.

**Preparation of Visual Simulations**

The visual simulations were developed using photographs taken with a 35 mm digital SLR camera. Various focal lengths from 40 to 70 mm were used with the intent to capture the maximum pixels and resolution for the simulation. Visual Nature Studio, widely used 3D GIS software, was used to model the turbine locations on terrain built from USGS digital elevation model data. The photo locations were camera matched in the software to render the turbines from the same viewpoint as the photographs taken on the ground. The resulting rendered turbine images were then photo composited into the photographs to create the simulations. Existing topographic and site data provided the basis for developing the initial digital model.

Site plans and digital data for the proposed wind turbines were used to create three-dimensional digital models of the planned turbine placements. These models were combined with the digital terrain model to produce a complete computer model of the wind farm. For each viewpoint, a render camera was placed in the Visual Nature Studio software. The aspect ratio of each render was then matched to the corresponding photograph and the rendered terrain was visually matched to the photographed terrain to confirm scale. Finally the resulting turbine images are matched in perspective, scale, and aspect ratio, are photo composited into the original digital photo base using Adobe Photoshop. This process produces accurate portrayals of how the given turbine models and placements would look on the given terrain and from the specified viewpoints after construction. Seasonal conditions including weather, air quality, vegetation (foreground and background) and color impact the quality of the compositions. These compositions are a representative example of the area without subjectivity.

**4.2.3.2 Existing Environment**

The existing visual resources are the natural and built features open to view in the project landscape. The combination of land, water, and vegetation patterns represent the natural landscape features that define an area’s visual character, while built features such as buildings, roads, and other structures reflect human or cultural modifications to the landscape. These natural and built landscape features or visual resources contribute to the public’s experience and appreciation of the environment. This section describes the broad scale regional and local
landscape settings that were used to establish appropriate viewpoints from which the project would be visible.

Regional Landscape Setting

The project is set in two distinct landscapes. One landscape is the areas where the turbines would be sited along ridges located on the northern plateau of the Columbia River Gorge on Underwood Mountain (Figure 2.1-1 Location of Proposed Whistling Ridge Energy Project). The other landscape is the Columbia River Gorge National Scenic Area which is outside the project but within the viewshed looking into the project area.

The Scenic Area extends 85 miles along the Columbia River, and includes portions of three Oregon and three Washington counties. Formed by ancient volcanoes and sculpted by floods, the Columbia River Gorge carves a corridor through the Cascade Mountains in Oregon and Washington as the river journeys to the Pacific Ocean.

The National Scenic Area Act designated for special protection 292,500 acres on both sides of the Columbia River from the outskirts of Portland-Vancouver in the west to the semi-arid regions of Wasco and Klickitat counties in the east. The Scenic Area is categorized into three areas: SMAs, GMAs, and Urban Areas:

- SMAs, which contain the most sensitive resources, total 114,600 acres and are managed by the USFS.
- GMAs, with 149,400 acres, include a mixture of historic land uses such as farming, logging, and cattle grazing. The Columbia River itself is currently designated as a GMA as well. Development on GMA lands is administered by the Gorge Counties and the Gorge Commission.
- Thirteen Urban Areas in the Gorge are exempt from any Scenic Area regulations: Cascade Locks, Hood River, Mosier, and The Dalles in Oregon, and North Bonneville, Stevenson, Carson, Home Valley, White Salmon, Bingen, Lyle, Dallesport, and Wishram in Washington. The Act’s second purpose is to protect and support the economy of the Gorge by encouraging growth in existing Urban Areas and by allowing future economic development in a manner that is consistent with protection and enhancement of resources.

The project area is outside of the Gorge Plan and no visual quality objectives or management designations have been established for the area. Areas south of the project within the Scenic Area are designated as Urban or GMA. The views from the Gorge into the project area were examined through viewpoint selection. This area of the Gorge, closest to the project, is considered to have a high visual quality with a moderate sensitivity based on the vividly memorable, and although the area is not free of visual encroachment, the visual resources join together with a moderate degree of unity.
Local Landscape Setting

The project site is on land managed for commercial forestry by S.D.S. Co., LLC and Broughton Lumber Company. All of the parcels on which the project is located are managed for a continual cycle of growth, harvest, and replanting. As a longstanding commercial forestry site, no old-growth forests exist in areas where the project is proposed. Many of the stands of trees on the sections of land that would have turbines on them are recently harvested and reforested. S.D.S. Co., LLC and Broughton Lumber Company implemented timber harvest plans on approximately 50 acres during 2003. Additional harvests covering approximately 100 acres are planned.

In areas that have not been recently harvested or that are not planned to be harvested before project construction surrounding the proposed wind turbines, trees would be harvested and most of the land would be replanted with seedlings. This clearing would allow for safe construction, and would reduce the potential for tree growth to interfere with the wind resource on the site during the commercial life of the project.

No visual quality objectives have been established in the project area beyond the harvest size and configuration requirements of the Washington Forest Practices Act. These cleared areas are considered a “forest conversion” under the Forest Practices Act and have no established visual quality objectives. These openings, to the extent feasible, would be reforested in accordance with typical commercial forestry management practices.

S.D.S. Co., LLC and Broughton Lumber Company own this commercial property in Skamania County, Washington. While the project is not located inside the Scenic Area, the access road for the proposed site is located in the Scenic Area. The Scenic Area requirements are addressed in Sections 2.20 and 4.2.1. In relationship to the visual quality of the area, there are views from the Scenic Area into the project area. The viewpoints and viewer types in relation to the roadway improvements within the Scenic Area have been considered in this analysis for consistency with the Scenic Area guidance and conformance.

SR 14 in this area is a recognized scenic roadway. Typically, this designation means that a scenic corridor management plan would be prepared to provide policy-level guidance in the local adoption of comprehensive plan policies, zoning, and other land use regulation. There is no scenic corridor management plan for SR 14 and, therefore, no regulatory control of aesthetic impacts within the corridor. However, the scenic roadway designation carries an additional level of care and scrutiny in the review of potential aesthetic impacts based on recognition, but not regulation.

The local landscape visual appearance is of moderate visual quality with a moderate level of sensitivity. The levels of vividness (memorable), intactness (free from visual encroachment), and unity are average within the broader landscape.

Viewpoints

To analyze the project’s effects on visual resources, viewpoints were selected to characterize the aesthetic character of the project area and the differing landscapes in or near the project. The existing views from these viewpoints are described below and illustrated with photographs.
Most of the viewpoints are at publicly accessible locations where most people would view the project. Individual viewpoints were chosen as being the most representative views for the different roads, population areas, and recreation areas where views of the wind turbines would occur. Figure 4.2-5 Locations of Simulation Viewpoints shows the locations of these viewpoints from outside and within the project area, and the distance and visible turbines from each viewpoint. Because the focus is on locations that are publicly accessible and would have the largest number of viewers (including residences), not every residential location has been studied. Residences from 5 miles to 1 mile of the project site are depicted on Figure 4.1-1.

Each viewpoint was assessed using the methodology described in Section 4.2.3.1, Methodology, as well as for its scenic quality and viewer sensitivity, and a rating was applied to provide an overall average for the area. This process established the existing conditions for each of the individual viewpoints from which the visual contrast or impacts of the project on these parameters could be measured. Viewpoints 6 and 9 were eliminated from additional analysis due to changes in the distribution of the turbine strings and inability to view the project from these viewpoints. Viewpoint simulations can be found on Figures 4.2-6 to 4.2-26.

**Pucker Huddle - Viewpoint 1 – Figure 4.2-6**

*Scenic Quality*

Viewpoint 1 is taken from SR 141, which is approximately 4 miles from the project and is a small connector providing access to the Indian Heaven Wilderness in the Gifford Pinchot National Forest. This highway also allows access to several rural communities including White Salmon, Husum, and Pucker Huddle. Most areas are unincorporated and several of the residences are recreational in nature with some year-round residences. As discussed in the review of the regional and local landscapes, no public roads pass through or are immediately adjacent to the project. Viewpoint 1 is a wide panoramic view of Underwood Mountain from SR 141 adjacent to the Pucker Huddle area.

The view encompasses the east side of the project area and the ridged lines of forest management areas are visible in the middleground of the viewshed. Natural openings are prevalent from this viewpoint with several natural appearing features of openings and vegetation that provide an interesting view. The BPA transmission lines bisecting the project area on the north and south ends can be seen from this viewpoint. The quality of the views from this viewpoint along SR 141 was rated as moderate, reflecting the fact that the landscape visible is relatively common in the region and has average scenic value. The ridge line along Underwood Mountain, which is in the area of the project, provides a degree of topographic interest when viewed with the other natural appearing features. The landscape visual scenic quality from this viewpoint is moderate.

*Viewer Sensitivity*

Traffic volumes along SR 141 are minimal and used for local traffic and recreating traffic in the summer months. Considering the distance of the project from this viewpoint (less than 5 miles), the minimal use of the highway, and the portion of the project that is visible from the viewpoint, the level of view sensitivity is considered low. This is based on the duration of the view from SR 141 and the low level of residential viewers from this viewpoint and the scenic quality rating.

Whistling Ridge Energy Project
Skamania County, Washington
Scenic Quality

Viewpoint 2 is an elevated view of the project from Strawberry Mountain east of the project area. The viewpoint encompasses the view that many of the residence would see from an elevated position above SR 141. This view is similar to Viewpoint 1 except that the man-made lines and features from forest management and power transmission are more prevalent. Several natural appearing features, including openings and vegetation, provide an interesting view in the middle ground with Underwood Mountain in the background. The quality of the views from this viewpoint above SR 141 was rated as moderate, reflecting the fact that the landscape visible is relatively common in the region and has average scenic value.

Viewer Sensitivity

When considering the distance of the project from this viewpoint (greater than 5 miles) and the portion of the project that is visible from the viewpoint, the viewer types (residential/recreational), and the scenic quality rating, the level of visual sensitivity is considered moderate.

Husum - Viewpoint 3 – Figure 4.2-8

Scenic Quality

This viewpoint captures the view from SR 141 northeast of the project area. This viewpoint would be the first view of the project from travelers moving south into the project area. The viewpoint encompasses the northern portion of the project from the highway, which is the closest viewing area from that vantage point. The foreground of the viewpoint is pastoral with a middle ground view of the hillsides and a background view of Underwood Mountain and the project area. The view is natural appearing with moderate to high levels of vividness, unity, and intactness in the foreground, middle ground, and background of the photo. The quality of the view from this viewpoint was rated moderately high because of the above-average quality and the unity of the man-made and natural features on the landscape.

Viewer Sensitivity

When considering the distance of the project from this viewpoint (greater than 5 miles), the duration of the view (roadway travelers), the portion of the project that is visible from the viewpoint, the viewer types (minimal residential/recreational), and the scenic quality rating, the level of visual sensitivity is considered moderate.

Auplund Road and Cook-Underwood Road - Viewpoint 4 – Figure 4.2-9

Scenic Quality

This viewpoint captures the view from the Ausplund, Cook-Underwood Roads where they meet and provide residential, agricultural, and forest management access to the area. These roads are connector and feeder roads that can be accessed from SR 14. This area is elevated from the
Columbia River Gorge National Scenic Area but is within its boundaries. The area has a mix of uses including agriculture, forest management, and some recreation. The foreground from the roadway is an agricultural setting with the middle and background views of forest vegetation and forest management areas. The view is natural appearing with moderate levels of vividness, unity, and intactness. The quality of the view from this viewpoint was rated moderate because of the average or typical views of this type in the project area.

**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (0.5 to 5 miles), the viewer types (roadway travelers), the portion of the project that is visible from the viewpoint, the viewer types (residential/roadway), and the scenic quality rating, the level of visual sensitivity is considered moderate.

**Willard – Viewpoint 5 – Figure 4.2-10**

**Scenic Quality**

This viewpoint captures the view from the small residential community of Willard. This area is accessible by a county road from SR 14 and used by residential and private forest management users. The view looks southeast into the project area and provides a panorama of the longest string of turbines. The foreground is a mixture of mixed conifer second growth stands and the middle ground is of mixed timber harvest openings and a transmission corridor. The background view is similar and the mixture of vertical and horizon lines and formations detracts from the overall vividness and unity of the view. The intactness of the views is moderated by the changes in line and form. The quality of the view from this viewpoint was rated moderately low to moderate.

**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (0.5 to 5 miles), the duration of the view (foreground screening), the portion of the project that is visible from the viewpoint, the viewer types (minimal residential), and the scenic quality rating, the level of sensitivity is considered moderate.

**Mill A – Viewpoint 7 – Figure 4.2-11**

**Scenic Quality**

This viewpoint captures the view from the old mill property west of the project area. This area is accessible from Willard Road and has a mixture of uses. The view is looking northeast into the southern end of the A turbine string. The foreground view is obstructed by the vertical lines of transmission towers. The middle ground view is of transmission corridors and extensive timber harvest openings. Many of the residential views are partially screened from the valley floor. There is a visual discord with the man-made alterations. The vividness, unity, and intactness appear uninviting and of moderate to low visual quality. The scenic quality rating for this viewpoint is moderately low.
**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (0.5 to 5 miles), the duration of the view (foreground screening), the portion of the project that is visible from the viewpoint, the viewer types (minimal residential), and the scenic quality rating, the level of sensitivity is considered moderate.

**Windance – Viewpoint 8 – Figure 4.2-12**

**Scenic Quality**

This viewpoint captures the view from the parking lot of the Windance Sailing Shop in Hood River. This area is across the Columbia River looking south into the project area from within the Scenic Area. Foreground views are of the City of Hood River and the middle ground captures portions of the Columbia River and the northern bank. The background is of Underwood Mountain and the project area. Beyond the foreground elements in the view the levels of vividness, unity, and intactness are considered average or above average in the context of the setting. The scenic quality rating for this viewpoint is moderate.

**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (greater than 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (roadway, residential, urban area, and river recreation), and the scenic quality rating, the level of sensitivity is considered low to moderate.

**Panorama Point – Viewpoint 10 – Figure 4.2-13**

**Scenic Quality**

This viewpoint captures the view from above Hood River at the Panorama Point within the Columbia River Gorge National Scenic Area looking north across the Columbia River into the project area. Foreground views are a composition of vegetation and residential dwellings. The middle ground encompasses the Hood River and the Columbia River area with the Underwood Mountain in the background. The levels of vividness, unity, and intactness are considered above average with the combinations of man-made structures and natural features in harmony with the view. The scenic quality rating for this viewpoint was rated moderately high.

**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (8–10 miles), the portion of the project that is visible from the viewpoint, the viewer types (roadway, residential), and the scenic quality rating, the level of sensitivity was rated low.
**I-84 Westbound – Viewpoint 11 – Figure 4.2-14**

*Scenic Quality*

This viewpoint captures the view from I-84 traveling westbound towards the project area from the east. I-84 is along the Columbia River Gorge National Scenic Area and views along this portion of the highway are generally directed towards the river and the distant scenery. Beyond the foreground view of the highway and other corresponding structures the view is generally intact with average or above vividness, unity, and intactness. Viewers traveling along this corridor have multiple line of sight transitions and this is considered to be average within those views. The scenic quality rating for this viewpoint was rated moderate.

*Viewer Sensitivity*

When considering the distance of the project from this viewpoint (8–10 miles), the portion of the project that is visible from the viewpoint, the viewer types (roadway), and the scenic quality rating, the level of sensitivity was rated moderate.

**Koberg Park – Viewpoint 12 – Figure 4.2-15**

*Scenic Quality*

This viewpoint captures the view across the Columbia River from Koberg Park. The foreground view of the river is a complete composition indicative of the area and the middle and backgrounds have a high level of vividness, unity, and intactness. The rail-line that bisects the view in the middle ground tends to blend into the scenery without distraction. This view is considered to be above average for the types of views that are throughout the Scenic Area. The scenic quality rating for this viewpoint was rated moderately high.

*Viewer Sensitivity*

When considering the distance of the project from this viewpoint (8–10 miles), the portion of the project that is visible from the viewpoint, the viewer types (recreational), and the scenic quality rating, the level of sensitivity was rated moderate.

**I-84 Eastbound – Viewpoint 13 – Figure 4.2-16**

*Scenic Quality*

This viewpoint captures the view from I-84 traveling eastbound towards the project area from the west. I-84 is along the Scenic Area and views along this portion of the highway are generally directed towards the river and the distant scenery. Beyond the foreground view of transmission structures the view is generally intact with average or above-average vividness, unity, and intactness. Viewers traveling along this corridor have multiple line of sight transitions and this view is considered to be above average within the context of those multiple views. The scenic quality rating for this viewpoint was rated moderately high.
**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (3 to 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (roadway travelers with fleeting views), and the scenic quality rating, the level of sensitivity was rated as moderately low.

**Viewpoint 14 – Viento State Park – Figure 4.2-17**

**Scenic Quality**

This viewpoint captures the view from Viento State Park, a popular recreation and rest area along the Columbia River. Landscape features are diverse and intact and the contrasts of the features have a high level of unity. This view is the open waters of the Columbia River in the foreground with rock features and vegetation in the middle ground and a background of mountains which provides an overall pleasing composition that is inviting to the viewer. This view is one of the less common views along the Gorge and has an above average scenic value. The scenic quality rating for this viewpoint was rated moderately high to high.

**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (greater than 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (recreational), and the scenic quality rating, the level of sensitivity was rated as moderate to high.

**Viewpoint 15 and 16 – Frankton Road and Fairview Road – Figures 4.2-18 and 4.2-19**

**Scenic Quality**

The viewpoints represent the view from the higher elevation residential areas west of Hood River. These views are across the Columbia River looking into the project area. Both of these roads are local access roads and traffic is considered low. Residential dwellings in these areas have developed based on the topographic and the views both north and south. Many of the views are screened to the north and take advantage of the view south into Oregon. Both of the photos have residential development in the foreground, which is common along these roadways. The middle ground is vegetation, some agriculture, and some forest management. The background is the ridge along the project area. These types of views are relatively common and of average scenic value when compared to the broader area. Vividness, unity, and intactness are moderate to high levels. The scenic quality rating for these viewpoints is moderate.

**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (greater than 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (residential), and the scenic quality rating, the level of sensitivity was rated as moderate.
Viewpoints 17 and 18 – Providence Hospital and Rosauers Parking Lot Hood River – Figures 4.2-20 and 4.2-21

Scenic Quality

The viewpoints represent the north and south views of the project from the City of Hood River. The foreground is an urban setting with a middle ground of vegetation that screen the background to some degree, providing a diverse composition of features. The views have a somewhat vivid appeal based mostly on the man-made features; however, the unity and intactness are below average and are visually discordant. This detracts from the background view. Viewers would generally be more focused on the business of the urban environment. The scenic quality of these viewpoints was rated moderately low.

Viewer Sensitivity

When considering the distance of the project from this viewpoint (greater than 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (urban/residential), and the scenic quality rating, the level of sensitivity was rated as low.

Viewpoint 19 – Columbia River Highway – Figure 4.2-22

Scenic Quality

This viewpoint represents the view of the roadway traveler on the Columbia River Highway (Highway 30) southeast of the project area. This view has a higher scenic quality and is more representative of the high quality views within the Columbia Gorge area. The foreground, middle ground, and background all have an above average arrangement of spaces in the landscape. The view appears intact and has a unity with the road and even the transmission line that is visible in the middle ground. The landscape provides diversity but not to the extent of clutter. This view is rated moderately high for scenic quality.

Viewer Sensitivity

When considering the distance of the project from this viewpoint (greater than 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (roadway travelers/sightseers), and the scenic quality rating, the level of sensitivity was rated as moderate.

Viewpoint 20 – State Route 35 – Figure 4.2-23

Scenic Quality

This viewpoint represents the view from SR 35, which is 4.6 miles south of Hood River. The viewpoint position is somewhat inferior with the industrial complex in the foreground. The middle and backgrounds looking into the project area from the southeast have an average scenic quality. The scenic quality rating for this viewpoint is moderately low.
**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (greater than 10 miles), the portion of the project that is visible from the viewpoint, the viewer types (roadway travelers/sightseers), and the scenic quality rating, the level of sensitivity was rated as low to moderate.

**Viewpoint 21 – Kollock-Knapp Road intersection with Scoggins Road – Figure 4.2-24**

**Scenic Quality**

This viewpoint represents the view from local area roadways at specific intersections where local area travelers might converge. These roads are old logging roads that have been upgraded to meet the local residential use. However, they are still used for logging and would be used in the construction portion of this project. This would include upgrading and in some instances widening the roads, which can have an effect on visual quality. The viewpoint position is somewhat inferior with the orchard fence in the foreground. The middle and backgrounds views are lost due to the foreground screening. The scenic quality rating assigned to this view is moderately low.

**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (1.5 miles), the portion of the project that is visible from the viewpoint, the viewer types (local area workers and minimal residences), and the scenic quality rating, the level of sensitivity was rated as low to moderate.

**Viewpoint 22 – Cook-Underwood Road intersection with King Road – Figure 4.2-25**

**Scenic Quality**

This viewpoint represents the view from local area roadways at specific intersections where local area travelers and workers might converge. These roads are old logging roads that have been upgraded to meet the local residential and commercial use. However, they are still used for logging and would be used in the construction portion of this project. This would include upgrading and in some instances widening the roads, which can have an effect on visual quality. The view from this intersection is very pastoral with a feeling of unity and intactness. Beyond the orchard in the middle ground, which adds some diversity to the composition, the view is above average for the area. The scenic quality rating assigned to this view is moderately high.

**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (1.5 miles), the portion of the project that is visible from the viewpoint, the viewer types (local area workers and minimal residences), and the scenic quality rating, the level of sensitivity was rated as moderate.
**Viewpoint 23 – Ausplund Road End – Figure 4.2-26**

**Scenic Quality**

This viewpoint represents the view from local area roadways at specific intersections where local area travelers might converge. These roads are old logging roads that have been upgraded to meet the local residential use. However, they are still used for logging and would be used in the construction portion of this project. This would include upgrading and in some instances widening the roads which can have an affect on visual quality. This view is from the end of the Ausplund Road, which would be used to access the area for construction and maintenance. Very few viewers beyond those associated with the project would see this viewshed. Taking out the vehicles in the foreground, the scenic quality rating assigned to this view is moderate.

**Viewer Sensitivity**

When considering the distance of the project from this viewpoint (less than 1 mile), the portion of the project that is visible from the viewpoint, the viewer types (local area workers and residence), and the scenic quality rating, the level of sensitivity was rated as low to moderate.

**4.2.3.3 Impacts**

This analysis examines potential direct aesthetic impacts during the construction, Operations and Maintenance, and decommissioning phases of the proposed project. Indirect impacts are not anticipated because the project is not expected to substantially induce regional growth to the extent that would result in significant changes to the offsite visual landscape.

For the proposed project, the primary concern is the potential aesthetic impacts of the proposed wind turbines. The project would consist of up to 50 wind turbines. Because of the heightened activity in the wind energy industry, pricing and availability of turbines are highly variable. Consequently, the specific turbine type and manufacturer has not been selected. However, it is likely that the turbines would be in the 1.2- to 2.5-MW range, and would measure approximately 426 feet in height (262-foot hub height and 164-foot radius blades). The diameter of the blade would be approximately 230 to 265 feet, depending on which turbine is selected. Each turbine’s three rotor blades would be made of laminated fiberglass. Turbine “strings” would include three to 21 turbines placed at approximately 350 to 500 foot intervals.

It is the ability of the landscape in question to accommodate both the size and density of the wind turbines that would determine the resulting visual impacts. Given its dimensions, there are few measures, other than the wind turbine color, that can be implemented to mitigate the visual impact of a wind turbine. Being available to the wind requires the turbines to be in a location that is open and highly visible.
The visual impact assessment was based on evaluating the changes to the existing visual resources that would result from construction and operation of the project. These changes were assessed, in part, by evaluating the “after” views provided by the computer-generated visual simulations and comparing them to the existing visual environment. Consideration was given to the following factors in determining the extent and implications of the visual changes:

- Changes in the affected visual environment’s composition, character, and valued qualities
- The affected visual environment’s context, including distance
- The extent to which the affected environment contains places or features that have been designated in plans and policies for protection or special consideration
- The number of viewers, their activities, and the extent to which these activities are related to the aesthetic qualities affected by the changes
- The distance factor was considered in the sensitivity rating for establishment of baseline and therefore becomes a factor in the impact assessment

Levels of impact were classified as high, moderate, and low:

- **High Level of Impact.** High levels of impact were assigned in situations in which turbines would be highly visible in areas with a high number of sensitive viewers, and would greatly alter levels of vividness, unity, and intactness, decreasing the level of visual quality. This is the largest number of viewers from that key viewpoint. The assessment does account for the number of viewers and would add that into the discussion.

- **Moderate Level of Impact.** Moderate levels of impacts were assigned in situations in which turbines would be visible in areas with moderate levels of visual sensitivity and viewers in which the presence of the turbines would moderately alter levels of landscape vividness, unity, and intactness.

- **Low Level of Impact.** Low levels of visual impact were found in situations where the project would have relatively small effects on overall landscape level attributes or where existing levels of landscape aesthetic quality are low or where there are low levels of visual sensitivity and a low number of viewers.

Much of the public input and comments received on the proposed project (made in various public forums prior to filing this Application) indicates that for some viewers, the presence of the wind turbines represents a negative impact because it alters the appearance of the rural landscape over a large area. The flashing of FAA aviation lights on the tops of turbines at night would similarly be considered a negative impact. For purposes of this analysis, the term “significant” may be defined as levels of visual impact that are rated “moderately high” to “high” from any given viewpoint. This does not mean that a particular location or the project as a whole poses a “significant” impact for the purposes of SEPA review. Moreover, while a particular viewpoint
may be characterized as having a “high” impact, that impact may be experienced by a relatively small number of individuals, or relate to a small portion of the project, and it does not account for the overall benefits of the project. Definition of the term “significant” in this context, however, is subjective and depends on many factors. For example, the degree to which impacts are adverse depends on the viewer’s location, the orientation of structures (such as homes), personal sensitivity, and the impact on view quality. In the final analysis, it is the comparative number of viewers most affected by the project that determines the overall impact. A project that significantly affects a small number of viewers may be offset by the fact that it may have a relatively low impact on a large number of viewers.

Construction

During construction, large earth-moving equipment, trucks, cranes, and other heavy equipment would be highly visible from nearby areas. At times, small, localized clouds of dust created by road building and other grading activities may be visible at the site. Because of construction-related grading activities, areas of exposed soil and fresh gravel that contrast with the colors of the surrounding undisturbed landscape would be visible.

In close-up views, particularly those seen by travelers on the segment of the local highway that passes around the project site and those seen from the closest residences, the visual changes associated with the construction activities would be highly visible and would have a moderate to high visual impact. From more distant locations, the visual effects would be relatively minor and would have little or no impact on the quality of views and are considered short-term.

Operation

Using the visual simulation, the potential levels of visual impacts from key project viewpoints have been evaluated and are summarized on Table 4.2-5. A detailed description for each viewpoint follows the summary table.

The project has the potential to create low to moderate levels of visual impact at key viewpoints. Not every potential view receptor in the project area has been documented. Selected viewpoints are representative of a variety and range of views in the project area. The photos used for the simulations show the worst-case seasonal conditions for visual contrast between the wind turbines and the primarily green and brown landscape backdrop. The period with the least visual contrast is anticipated to occur when there is snow cover and gray skies.

---

2 Additionally, for reasons related to commercial viability and engineering feasibility, the project is proposed as an integrated whole, not a series of separate components where parts of the whole may be removed due to subjective, perceived visual effects.

</tbody>
</table>

Atmospheric haze varies by location, season, time of day, and weather patterns. In creating photo composite visual simulations the aim is to match the haze level on the rendered turbines to the observable haze present in the photograph. This is done visually by comparing the haze effects on the photographed terrain near the turbines to the rendered haze effects on the rendered terrain. This is then translated into a worst case (lower than expected) haze visibility setting for the turbine renders. The result is that the turbines would be slightly more visible in the final
composites than they would actually be if an observer were standing on the ground viewing them from the exact place, date, and time that the photos were taken.

**Viewpoint 1: Pucker Huddle**

From Viewpoint 1, approximately 25 turbines would be visible on the ridge tops at distances of 0.8 to 3 or more miles. Figure 4.2-6 illustrates the simulated views from Viewpoint 1 on SR 141 above Pucker Huddle, looking west into Underwood Mountain for the most conservative scenario of a 50-turbine project, with 426-foot high turbines. At the distance depicted in the photo, the visual clutter of more turbines has more impact than the considerable scale of the larger turbines. The composition would be silhouetted against the sky, increasing their visual impact. However, the distance and the line of sight from the residential areas would minimize the contrast. The presence of the turbines would reduce the scene’s degree of intactness by introducing a large number of highly visible engineered vertical elements.

The potential visual impact from Viewpoint 1 would range from low to moderate.

**Viewpoint 2: Strawberry Mountain**

From Viewpoint 2, approximately 22 turbines would be visible on the ridge tops at distances greater than five or more miles. Figure 4.2-7 illustrates the simulated views from Viewpoint 2 on SR 141 above Pucker Huddle, looking west into Underwood Mountain for the most conservative scenario of a 50-turbine project, with 426-foot high turbines. At the distance depicted in the photo, the background is silhouetted against the sky, increasing the impact of the number of turbines as opposed to the size of the large turbines. The introduction of vertical structures in the background of the view would add to the horizontal and vertical disruptions already within the existing view. The intactness would be compromised minimally with the addition of these features.

The potential visual impact from Viewpoint 2 would range from low to moderate.

**Viewpoint 3: Husum**

From Viewpoint 3, approximately 27 turbines would be visible on the ridge tips at a distance greater than five miles. Figure 4.2-8 illustrates the simulated views from SR 141 traveling south into the project area. Travelers moving along this highway are generally using the road to access recreation areas or for leisurely drives. Residential viewers would be screened to some degree from the view based on vegetation, landscaping, and the line of sight from the valley floor. Introduction of these vertical structures in the background of this view would decrease the intactness of the landscape, based on the numbers of turbines that would be visible. The composition of the view would be altered with the introduction of these engineered structures and would be apparent on the horizon to the travelers and residence in the area. Due to the low levels of viewers, duration of the views, and viewer awareness, the visual impact from Viewpoint 3 is considered moderate.
**Viewpoint 4: Ausplund and Cook-Underwood Roads**

From Viewpoint 4 approximately 14 turbines would be visible looking northwest from the roadway. Figure 4.2-9 illustrates the simulated view from the roadway at the intersections of Ausplund and Cook-Underwood Roads. Because of the position of this viewpoint (direct line of sight) and its distance from the turbines, the turbines apparent scale would be visible and apparent. The presence of the turbines would likely have a moderate effect on the vividness of the existing view and a moderate impact on the overall sense of unity and intactness by the roadway and residential viewers.

The potential visual impact from Viewpoint 4 would be moderate.

**Viewpoint 5: Willard**

From Viewpoint 5, approximately 24 turbines in turbine strings A and B would be visible from screened views from residences in the area of Willard. Figure 4.2-10 shows the simulated view from Viewpoint 5 in the northern portion of the project looking southeast. These turbines would be located in the ridge tops at distances ranging from 1 to 3 miles from this viewpoint. Because the turbines would be seen against the sky at medium range and screened in many residential views, they would still be visible in the background. This would reduce the visual unity and intactness minimally when compared to the existing components in the landscape. The wind turbines would be arrayed uniformly along the ridgeline and would create a moderate change in the setting’s existing low to moderate visual quality.

The potential visual impact from Viewpoint 5 would be moderate.

**Viewpoint 7: Mill A**

From Viewpoint 7, approximately 35 turbines in strings A and B would be visible in the foreground, middle ground, and background of this view. The ridgeline is located 1.5 miles or more from Viewpoint at Mill A. Figure 4.2-11 shows the simulated view. The turbines would be seen against the sky. The presence of the long line of turbines may create a slight increase in the vividness of this view. The unity of the view would be decreased further by the long turbine line and the intactness of the view would be moderately compromised compared to the existing view.

The potential visual impact from Viewpoint 7 is considered to be low to moderate.

**Viewpoint 8: Windance**

From Viewpoint 8, fewer than seven turbines can be seen in the background of the landscape and more than 5 miles from the viewpoint. Figure 4.2-12 shows the simulated view. The scenic quality with advent of the turbines when seen from this distance is expected to minimally decrease the level of vividness, unity, or intactness of the landscape view. Recreational users in the Gorge area are water related and their line of sight is generally along the river and river banks. Although the turbines would be visible on the far horizon it is not expected to decrease the existing quality of this view.
The potential visual impact from Viewpoint 8 is considered to be low.

**Viewpoint 10: Panorama Point**

From Viewpoint 10, approximately 11 turbines can be seen in the distant background of the view. Figure 4.2-13 shows the simulated view. Although the turbines would be visible on the far horizon, it is not expected to decrease the existing quality of this view. However, because of their relatively small size at this viewing distance, they would not likely detract from views across the Columbia River Gorge National Scenic Area. The visible turbines would have little effect on this view’s vividness, unity, and intactness.

The potential visual impact from Viewpoint 10 would be low.

**Viewpoint 11: I-84 Westbound**

From Viewpoint 11, approximately 19 turbines would be visible in the distant background to roadway travelers looking west into the project area from I-84. Figure 4.2-14 shows the simulated view. Although the turbines would be visible to travelers on the far horizon, their presence is not expected to decrease the existing quality of this view, because of their relatively small size at this viewing distance. The visible turbines would have a minimal effect on this view’s vividness, unity, and intactness.

The potential visual impact from Viewpoint 11 was rated as moderate to low.

**Viewpoint 12: Koberg Park**

From Viewpoint 12, approximately 17 turbines would be visible in the distant background to recreational users of the park and river. The view looks west into the project area. Figure 4.2-15 shows the simulated view. Although the turbines would be visible to the viewers on the far horizon, it is not expected to decrease the existing quality of this view to a great degree, because of their relatively small size at this viewing distance. The visible turbines would have a minimal effect on this view’s vividness, unity, and intactness.

The potential visual impact from Viewpoint 12 was considered to be moderate.

**Viewpoint 13: I-84 Eastbound**

From Viewpoint 13, approximately eight turbines would be visible in the background to roadway travelers looking west into the project area from I-84. Figure 4.2-16 shows the simulated view. This view for travelers would be of short duration. Although the turbines would be visible to travelers on the horizon, it is not expected to decrease the existing quality of this view because of the number of turbines visible and the partial screening from the middle ground ridgeline. The visible turbines would have a minimal effect on this view’s vividness, unity, and intactness for these reasons.

The potential visual impact from Viewpoint 13 was rated as moderate to low.
**Viewpoint 14: Viento State Park**

From Viewpoint 14, approximately 20 turbines in the background would be visible to the recreational users of the area. Figure 4.2-17 shows the simulated view. Although the water-related recreational activities would have the line of sight more related to the water and river banks, the recreational users moving through this area would be affected by this contrast in the view. The vividness of the scenic quality may be positively or negatively affected, depending on the user perception of turbines in the background. The unity and intactness of the existing view would be moderately compromised and the visible turbines would have a moderate effect on the view’s scenic quality compared to existing conditions, due to the distance from the State Park and activities in the foreground and middle ground.

The potential visual impact for Viewpoint 14 was considered to be moderate.

**Viewpoints 15 and 16: Frankton and Fairview Roads**

From Viewpoints 15 and 16, approximately 10 and eight turbines can be seen, respectively. Figures 4.2-18 and 4.2-19 show the simulated view. At a distance of 5 miles or more this contrast would have a minor effect on the overall visual impact. Consequently, because the prominence of the turbines in the view would be low, the turbines would have a minor effect on the vividness, unity, and intactness from this viewpoint.

The potential visual impact from this viewpoint would be moderate.

**Viewpoints 17 and 18: Province Hospital and Rosauers Parking Lots Hood River**

From Viewpoints 17 and 18, only two and three turbines can be seen, respectively, and they are diminished by the distance. Figures 4.2-20 and 4.2-21 show the simulated views. At this distance, viewers would have to scan the horizon to find the turbines. Consequently, minor effect or negligible effects to the scenic quality is expected to be low and was rated as low.

**Viewpoint 19: Columbia River Highway**

From Viewpoint 19, approximately nine turbines are visible in the distant background. Figure 4.2-22 shows the simulated view. Although the turbines would be visible in the background the viewer would have to have a focused orientation to see them in the landscape. The amount of turbines and the limited prominence based on the distance is expected to have a minimal effect on the scenic quality from this viewpoint.

The potential visual impact from this viewpoint would be low.

**Viewpoint 20: State Route 35**

From Viewpoint 20, approximately 20 turbines could potentially be seen. Figure 4.2-23 shows the simulated view. Given the distance of more than 10 miles from the viewpoint to the wind turbines, it would be difficult to see them out on the horizon unless the conditions and lighting were perfect. Implementation of the project is not expected to change the scenic quality from this viewpoint.
The potential visual impact from this viewpoint would not change from existing.

**Viewpoint 21: Kollock-Knapp Road at the intersection with Scoggins Road**

From Viewpoint 21, approximately three turbines can be seen. Figure 4.2-24 shows the simulated view. This area would be within 1.5 miles of the project and the turbines would be highly visible at these intersections. However, minimal use of these roads beyond a few residences and workers reduces the viewer types. Regardless, the impacts of the turbines on the landscape would affect the scenic quality of the view.

The potential visual impact from this viewpoint would be moderate.

**Viewpoint 22: Cook-Underwood Road at the intersection with King Road**

From Viewpoint 22, approximately seven of the 22 turbines can be seen. Figure 4.2-25 shows the simulated view. This area would be within two miles of the project and the turbines would be highly visible at these intersections. However, minimal use of these roads beyond a few area residences and workers reduces the viewer types and the viewer numbers. Regardless, the impacts of the turbines on the landscape would affect the scenic quality of the view for those viewers.

The potential visual impact from this viewpoint would be moderate.

**Viewpoint 23: Ausplund Road End**

From Viewpoint 23, approximately eight turbines can be seen. Figure 4.2-26 shows the simulated view. This area would be within one mile of the project and the turbines would be highly visible at the end of this project access road. However, very minimal use of these roads beyond workers associated with forest management reduces the viewer types. Regardless, the impacts of the turbines on the landscape would affect the scenic quality of the view.

The potential visual impact from this viewpoint would be moderate.

As noted above, visual impacts relate to the subjective perceptions of viewers. For many viewers, the location of the project, including the limiting effect of topography, tree cover, the relatively significant distance to surrounding residences, and the orientation of the project vis-à-vis viewers, minimizes visual impacts. However, the project is proposed in a location with a robust wind resource and relatively easy and close access to consumers of renewable energy. Consequently, the project would be seen and perceived by many viewers, and it would alter the landscape. Opportunities to minimize and mitigate visual impacts are limited. Simulations have been prepared to compare the impacts of different colors for the turbines. Although a brown turbine color would reduce visual contrast in views where the turbines are seen against a landscape backdrop, it would accentuate the visibility of the turbines in views where they would be seen against the sky. In addition, the brown color would have a greater contrast when snow is on the ground. Because the turbines are most frequently seen against the sky, particularly in close-range views where visual concerns are the greatest, a non-reflective flat neutral gray or light color is recommended as the better choice for minimizing aesthetic impacts.
Decommissioning Impacts

Decommissioning would consist of removing aboveground equipment, such as turbine and meteorological towers and their associated foundations, to a depth of 3 feet bgs. Wind turbine foundations below 3 feet would remain. The ground surface would be regraded to natural contours and revegetated to a natural condition.

For several years after decommissioning, site disturbance would be visible upon close examination. The visual impacts of those aboveground elements that are not removed would remain. During the decommissioning process, similar impacts to those experienced during construction would occur but to a lesser extent because less construction material would be removed than was delivered to the wind turbine sites.

4.2.3.4 Mitigation Measures

Because the turbines are most frequently seen against the sky, particularly in close-range views where visual concerns are the greatest, a non-reflective flat neutral gray or light color is recommended to minimize aesthetic impacts.

4.2.4 RECREATION

4.2.4.1 Inventory of Facilities

The primary recreation activities within Skamania County are camping, hiking and fishing. The USFS maintains numerous campgrounds, hiking trails and wilderness areas. Congress created the Mount St. Helens National Volcanic Monument, located in the northwest corner of Skamania County, following the 1980 eruption of the volcano. The Lewis and Clark Trail Highway follows the Columbia River through Skamania County. The Columbia River Gorge National Scenic Area is located south of the project site area. Informal recreational activities such as hunting, hiking and mountain biking exist subject to landowner approval.

Recreational facilities or activities available closest to the project site are as follows:

- Hiking and horseback riding along Buck Creek Trail
- Husum Hills Golf Course
- BZ Corners Boat Launch
- Underwood Park/Community Center
- Drano Lake Boat Ramp

Summer recreational activities include water sports such as fishing, swimming, boating, river rafting, kayaking, water skiing, and wind surfing; as well as camping, biking, hiking, horseback riding, hunting, picnicking, and other outdoor sports. Some of these activities continue into the winter, weather permitting. Sightseeing is a popular year-round activity in the Columbia River Gorge.
Table 4.2-6 lists recreational facilities and activities available within a 25-mile radius of the project site or beyond; the radius is centered somewhat near the middle of the project site (Figure 4.2-27 Key Recreation Viewing Areas and Recreational Facilities within Approximately 25 Miles). This study area covers forests and wilderness areas, wildlife areas, boat launches, state parks, county parks, city parks, trails, campsites, and museums.

Recreation Facilities and Key Viewpoints
Within Approximately 25 Miles

Source: GeoDataScape.
Job No. 33758687

Whistling Ridge Energy Project
Skamania County, Washington
No Skamania County recreation facilities are within five miles of the proposed project. The closest County facility would be the Underwood Park and Community Center, located near Underwood just off of Cook-Underwood Road (approximately 6 miles south). The community center has a large gymnasium, stage, kitchen, and meeting room; while the park has soccer fields, a pavilion, and a playground.

A notable recreational facility is Doug’s Beach State Park, located approximately 20 miles east of the site. Doug’s Beach is heavily used by windsurfers in the summer and is considered by many to be the premier expert windsurfing site in the Gorge and perhaps the entire western United States (Columbia River Gorge National Scenic Area 1992).

Two national trails, the Lewis and Clark National Historical Trail and the Oregon Pioneer National Historic Trail, are located within five miles of the proposed facility. These trails roughly follow Highway 14 and Interstate 84, respectively. There are no national trails located within 5 miles of the proposed facility. Within five miles, the White Salmon River is designated as a wild and scenic river, and within 25 miles, the Klickitat River is also designated.

The Gifford Pinchot National Forest, which includes Mount St. Helens National Volcanic Monument, is located approximately 10 miles west and north of the site. The Mount Hood National Forest is located approximately 20 miles south of the site. The Columbia River Gorge National Scenic Area is located immediately south of the site. The Scenic Area is a popular visitor tourist destination. Recreation activities in the Scenic Area include hiking, mountain biking, windsurfing, camping, fishing, boating, wildlife/bird watching, wildflower viewing, photography, picnicking, and rock climbing.

4.2.4.2 Established Plans and Policies

Skamania County completed a Parks and Recreation Master Plan in 2001. This plan outlines goals, policies, objectives, and important background information in order to guide recreational development in the County. There are no County Parks within five miles of the proposed facility.

The Scenic Area encompasses portions of six counties within Oregon and Washington. In 1987, the States of Washington and Oregon entered into the bi-state compact to form the Columbia River Gorge Commission. In 1991, the Columbia River Gorge Commission adopted the National Scenic Area Management Plan, which acts as the comprehensive plan within the Scenic Area.

The goals, objectives, policies, and guidelines for the Scenic Area provide a framework for guiding actions of the various public and private recreation providers in the Scenic Area. Overall goals, objectives, and policies include:

- Protection of the resources
- Scenic appreciation and scenic travel corridors
- River access and protection of the treaty rights
Interpretation/education
Trails and pathways
Transportation
Coordination

The Recreation Development Proposals List was originally created in 1992 as part of the Recreation Development Plan in the Management Plan for the Columbia River Gorge National Scenic Area. This list highlights selected sites and proposed projects at those sites that, when implemented, would best achieve the recreation goals and objectives of the Management Plan. The proposed projects would be funded by local, state and federal funds; however, it is unknown if any of these projects are funded or have been completed. The following sites identified as proposed improvement projects in the plan are within approximately 25 miles of the site:

- **Wind River**: develop river access park on the site emphasizing day-use activities
- **Drano Lake**: expand the existing facility and provide an additional launch lane, a dock, and vault toilets
- **Spring Creek Hatchery**: create a coordinated and cooperative plan, design, and management program
- **White Salmon River**: develop small to moderate-sized day-use facility emphasizing bank fishing opportunities
- **Klickitat River County Park**: improve campsites, trail/river access, and signage
- **Doug’s Beach State Park**: conduct cultural resource investigations at the site
- **Mayer State Park**: develop overnight camping, day-use parking, picnicking, and limited interpretive facilities
- **Hudson Hill**: acquire property by the USFS and develop a walking path and viewpoint
- **Mosier Waterfront**: develop a water-oriented, multipurpose day-use facility with windsurfing rigging/launching area, a swimming beach, picnic area, and a moderate to large parking area
- **Historic Columbia River Highway State Trail, Twin Tunnels Segment**: develop overnight camping area, bicycle parking, viewpoints, and picnicking

There are no new parks or recreation facilities planned within a five-mile radius of the site. There are no existing Skamania County ordinances or regulations that would require a dedication of land for recreation facilities, or money in lieu thereof, as a result of the proposed development. Although ordinances of this type could be adopted in the future, it is unlikely that Skamania County would assess such requirements against the development.
No federal recreation regulations apply to the site, nor are there federal or state plans for recreation facilities in the site.

### 4.2.4.3 Impacts

#### Construction Impacts

A majority of the construction workers are expected to be within daily commuting distance of the site. At peak construction periods, some workers may seek temporary housing in apartments or motels, or may make private arrangements for recreational vehicles. Existing limits on the length of stay in public camping areas would minimize any potential impacts on park users. Workers would be more likely to use the facilities on weekdays rather than busy weekends, so minimal impacts to park and recreation facilities are expected from construction workers.

#### Operational Impacts

In addressing the impacts to the Scenic Area and recreation opportunities in proximity to the project area we evaluated how the project would affect the overall goals, objectives, and policies listed above.

- **Protection of Resources.** The project would not decrease any resources within the Scenic Area. No recreation resources would be lost in the Scenic Area and only a small portion of an existing road would be affected by this project through upgrading of the road for access.

- **Scenic Appreciation and Scenic Travel Corridors.** Impacts to scenic areas and highway are listed in Section 4.2.3. Key viewing areas for recreation and the visual impacts are also found in Section 4.2.3 and disclose the distance of these areas from the project. The assessment for how the recreation visitor would view the project is assessed from these viewpoints. The project would have minor to moderate effects on the visual quality of the area as viewed from these recreation areas.

- **Resource Based Recreation.** No resource based recreation within the Scenic Area is expected to be affected by the project. No resources are within or in proximity to the project area.

- **River Access and Protection of Treaty Rights.** This project is on private lands outside of the Scenic Area and would have no effect on River Access and Treaty Rights.

- **Interpretation/Education.** An opportunity to provide alternative energy interpretation and education could be included in this project and further the goals of the Scenic Area.

- **Trails and Pathways.** The project would not affect any trails or pathways in the Scenic Area. There may be some distant views of wind turbines from trails. Key recreation and trails viewpoints are assessed in Section 4.2.4.
• **Transportation.** Use of the portion of the SR 14 and portions of Cook-Underwood Road that are within the Scenic Area to access the project would be upgraded but would have no effect on movement of recreational travel or access. It may increase the ability to access areas outside of the Scenic Area.

• **Coordination.** Coordination with the development of any of the projects set forth above within the Scenic Area would be ongoing throughout the timeframes of the project through construction and maintenance to assist in meeting overall goals, objectives, and policies.

Based on these factors, it is expected that the project would not “unreasonably diminish the scenic, recreational, and fish and wildlife values present in the area” (Wild and Scenic Rivers Act, 16 USC 1271-1287), so no impacts to wild and scenic rivers would occur. The project would not have a direct impact on any recreation area in the sense of impairing access, diminishing use, or restricting planned installations and improvements. The project would affect the visual experience of visitors in some locations (Figure 4.2-27 Key Recreation Viewing Areas and Recreational Facilities within Approximately 25 Miles). See Section 4.2.3 Aesthetics for more information about visual and aesthetic qualities and impacts.

### 4.2.4.4 Mitigation Measures

Impacts to recreation users during the construction phase would primarily result from dust and noise from construction equipment. While the project would not affect any trails or pathways in the Scenic Area, there may be some distant views of wind turbines from trails during operations. Because they are high on the ridge, no mitigation measures are proposed other than painting the turbines a flat gray. See Section 2.11 Emission Control and 4.1 Environmental Health for mitigation measures proposed for air quality and noise during construction. See Section 4.2.3 Aesthetics for a discussion of visual and aesthetic impacts and mitigation measures.

### 4.2.5 HISTORIC AND CULTURAL PRESERVATION

#### 4.2.5.1 Introduction

In 2003, CH2M Hill conducted a cultural resources survey at the proposed location for the Whistling Ridge Energy Project and site vicinity in order to assess the potential for such impacts. This survey was designed to identify, evaluate, and record prehistoric and historic cultural resources in accordance with Chapter 36 CFR §800. The survey objectives include identification of archaeological resources and historic properties that might be considered eligible for nomination to the National Register of Historic Places located within the area of potential effect for the development. The area of potential effect is shown on Figure 4.2-28, and includes a cumulative total of approximately 1,152 acres.

Area of Potential Effects

Revised Figure 4.2-28
Whistling Ridge Energy Project
Skamania County, Washington
The results of the survey and its findings have been reviewed by URS and no deficiencies were found.—URS expanded the study area to include the new road access, West Pit Road, and completed a file search of this area at the Washington State Department of Archeology and Historic Preservation (DAHP) in July 2009. The file search revealed no archeological or historical sites. An inventory of the new access road survey of portions of the project site would and previously recorded resources will be revisited and forms updated, as appropriate, will be conducted in the spring-fall 2009 by a URS archeologist to confirm the findings as part of preparation of the Environmental Impact Statement.

**Study Methodology**

This cultural resource assessment included a file search at the Washington State Department of Archaeology and Historic Preservation. Cultural and environmental background and history of the project vicinity was researched in order to provide an interpretive context for cultural resources potentially present in the project area. An intensive pedestrian inventory (survey) of all wind energy facility areas was conducted, and a windshield survey was conducted of proposed roads and road improvements. Literature was reviewed to examine the location and nature of potential traditional cultural properties (TCPs) in the project area. Potential TCP resources were sought during the field survey. The study methodology employed follows applicable NEPA regulations and is also consistent with US Secretary of Interior Standards for cultural resource survey and documentation under Section 106 of the National Historic Preservation Act (NHPA).

**4.2.5.2 Regional Context**

The cultural/historical sequence for the project vicinity is fairly well known, and was most recently provided by Griffin and Churchill (2001), but is also discussed by Beckham et al., (1988). Table 4.2-7 summarizes the prehistoric cultural/historical sequence in the project vicinity. The table is based on a synthesis of reports on archaeological sites and material cultural remains in the project vicinity. More information about the prehistoric cultural sequence can be found in Beckham et al. (1988).

Sequence defined by archaeological sites and material cultural remains

The prehistoric cultural/historical sequence of the project area can be divided into three broad periods (Griffin and Churchill 2001). The **Early Period** began about 11,000 years BP and lasted until about 4,500 years BP. Cultural groups during the start of this period relied primarily on big game for subsistence. Botanical resources also were heavily used, although archaeological evidence for such is not plentiful. Few, if any, permanent dwelling or architectural structures are known from the early part of this period. However, the later part of this period is marked by an increased reliance on fish and botanical resources, and the introduction or increase in the use of semi-subterranean house structures. The appearance of such structures marks a decrease in mobility and a general increase in sedentism, particularly in winter months.

Architectural features, such as semi-subterranean house pits and food storage (cache) facilities marks the **Middle Period** (4,500-250 years BP). Such structures dating to this period are often found grouped in village configurations along streams and river confluence areas. Based on these architectural features, it is evident that cultural groups were sedentary during winter months. During this time, cultural groups continued to rely heavily on riverine and botanical resources, although large game animals were also used.

The **Late Period** (250 years BP [ethnographic present]) coincides with the introduction of the horse, resulting in increased mobility and a greater dispersal in settlement and access to a wider array of economically useful resources. Changes in material culture during this time period reflect the exploitation of a wider array of resources, as well as the increased access to European firearms and metal tools. During this period, cultural groups experienced drastic demographic changes as a result of European disease epidemics, the influx of European settlers and explorers, and related events (Griffin and Churchill 2001, Masten and Galm 1989, Beckham et al. 1988).

It is important to recognize that most evidence for prehistoric cultures is derived from lowland sites located near streams. Archaeological evidence in upland areas, such as the project vicinity, has not been extensively documented or explored. Upland forested areas are considered to be of
lower archaeological sensitivity because these areas are often removed from permanent, resource bearing water sources, and are generally thought to lack the wider array of natural resources normally found in lowland and/or riverine settings. Upland forested areas have not yet yielded evidence of prehistoric seasonal, semi-permanent, or permanent settlements.

### 4.2.5.3 Cultural Background

The project vicinity is ethnographically important to the Yakama Indian Nation. Information about the ethnographic period has been developed by the Yakama through elder testimony (oral history) and is also found in early accounts of European exploration of the Columbia River and the Northwest. Beckham et al. (1988) and Griffin and Churchill (2001) provide detailed descriptions of the ethnographic background of the project site and its surrounding area.

Briefly, the Columbia River Gorge was traditionally used by several cultural groups: the Wishram, White Salmon, and Cascades groups (Eastern Chinookan linguistic group) and the Yakama and Klickitat groups (Echeesh-Keen linguistic group) (Griffin and Churchill 2001). These groups used the Columbia River and its tributaries. Although the groups established territorial boundaries (usually based on geography), these boundaries were loose. The groups subsisted on a seasonal round of resource procurement based on resource seasonality and availability (Griffin and Churchill 2001). While upland and inland resources were seasonally utilized, permanent or semi-permanent villages were located along streams and other permanent water sources.

Euro-American exploration by Lewis and Clark, the Northwest Fur Company, and Hudson’s Bay Company describe the indigenous cultural groups that settled along the Columbia River. Accounts of the settlements of the Wishram, White Salmon, Cascades, Yakama and Klickitat by these early explorers confirm the land-use pattern described by ethnographic informants. The implication of this use pattern for cultural resources is that evidence of cultural activity in upland and inland areas may not be evident through material remains, if it exists at all. Rather, most archaeological evidence for ethnographic and ethnohistoric activity is expected to be found in lowland areas along major rivers and streams.

European-American settlement in the northwest directly resulted in the depopulation and displacement of native cultural groups. A temporary Indian Reservation, the White Salmon Reservation, was established at the mouth of the White Salmon River in 1856. After two years, the residents of the reservation were moved to the present-day Yakama Reservation, and Euro-American homesteaders quickly established homesteads in place of the old reservation. In 1855, a treaty was signed in which the Confederated Yakama Tribes ceded their traditionally used lands to the Government but reserved their rights, through the Treaty of 1855, to fish at traditional locations along the Columbia and its tributaries, and to hunt in their traditional lands as long as the lands remained open and unclaimed. Today, the Confederated Tribes and Bands of the Yakama Nation include 14 tribes and bands from at least three different linguistic groups (Griffin and Churchill 2001).

### Historic Setting

Relevant themes of historical significance include homesteading, logging, development of dams, railroading, development of fisheries, and recreation. Homesteading in the area did not fully
develop until 1857, when the Yakama Tribes were forcibly relocated from the Columbia River area. The Donation Land Act of 1850 enabled settlers to stake claims along the Columbia and its tributaries. The settlers pursued agriculture, established orchards, vineyards, and other crop fields groups (Griffin and Churchill 2001).

The development of the logging industry and dams coincided. Early lumber companies established dams to aid in the transport of timber. Timber harvest began in the White Salmon River area in the late 1800s. Dams were constructed at the mouths of most major tributaries to the Columbia River. Later, hydroelectric dam projects replaced the early logging dams in function. However, some remnants of these early structures remain in the area. The effects of these early logging dam construction activities on local fisheries are not well understood, but were likely harmful. The subsequent hydroelectric dams are known to have affected fisheries negatively. Although evidence of early dams may have been obliterated or inundated due to subsequent dam construction, evidence of early old-growth logging activities can be seen in upland areas, in the form of large stumps, springboard notches, logging roads, etc. (Griffin and Churchill 2001).

Development of the railroad in the Columbia River Gorge reached fruition by 1908. The complex history of local and regional railroad development cannot be reviewed here. However, it is important to note that the rail line paralleled the Columbia River and destroyed native fisheries and sites important to indigenous cultural groups. Evidence of the railroad appears in lowland areas, although the logging activities that took place in upland areas may be related to railroad construction (i.e., timber harvest for railroad ties may have taken place locally). The railroad was an important means of transportation for the area, and aided in the distribution of locally produced crops and goods to areas throughout Washington and Oregon. Other than small local roads, the railroad was the only means of transportation through the Columbia River Gorge until the 1920s (Griffin and Churchill 2001).

### 4.2.5.4 Cultural Resource Assessment

**Pre-Field Research**

Preliminary research consisted of a Department of Archaeology and Historic Preservation file search and literature review, a review of previously documented cultural resource in the project vicinity, and a review of previous cultural resource assessments conducted in the project vicinity.

On July 3, 2003, Ms. Raena Ballantyne, a CH2M HILL Cultural Resource Specialist, visited the Department of Archaeology and Historic Preservation in Olympia, Washington to determine whether cultural resources have been previously documented in the project area. In July 2009, Ms. Michelle Stegner, a URS Cultural Resource Specialist, expanded the study area to include the access road located outside of the Columbia River Gorge National Scenic Area. This search provided basic information on the types and frequency distributions of cultural resources present or expected to be present in the project area, and also provided cultural context information.

No previously recorded cultural resources were documented in the area of potential effect for the project or the access road.
A number of cultural resources have been recorded outside of the project area in the project vicinity. Table 4.2-8 lists the known/recorded cultural resources and other pertinent information.

a. State Historic Preservation Officer

Native American Consultation

To initiate Tribal consultation, SDS Lumber Company invited Yakama tribal members to visit the project area in October 2007. Correspondence has been sent to cultural resource representatives of the Confederated Tribes and Bands of the Yakama Indian Reservation by SDS Lumber Company on November 4, 2008, requesting information on archaeological sites, traditional cultural properties, or any other concerns that the Tribe might have with this development. Two letters have been received from Chiefs of Tribes of the Yakama Nation, from Chief Wilbur Slockish of the Klickitat Tribe and from Chief Johnny Jackson of the Cascades Tribe. Neither letter identifies any traditional cultural properties or archaeological sites within the project site. Copies of these letters are attached in Appendix F.

Field Survey Results

On August 12–14, 2003, Dr. James C. Bard, Mr. James J. Sharpe, and Ms. Raena Ballantyne, CH2M HILL Cultural Resource Specialists, conducted an intensive cultural resource inventory survey of the proposed area of potential effect. Proposed new roads and proposed upgrades to existing roads were inventoried using windshield survey methodology. Special attention was given to exposed road cut profiles and areas where streams or drainages crossed roadways. Each proposed turbine string and the proposed substation area were inventoried in a pedestrian survey using transects spaced 15 to 25 meters apart. The survey corridor width was 150 feet on each side of the hypothetical turbine centerline, for a total corridor width of 300 feet on each turbine string. The cultural resource specialists examined areas of exposed soils, rodent burrows, backdirt piles, upturned rootwads of trees, etc. Exploratory presence/absence shovel testing in the project area was not conducted. In some areas, surface duff and leaf litter was scraped away from boulder outcappings and the forest floor to improve ground visibility. The project area lies on upland ridge top areas that are considered low in prehistoric archaeological sensitivity.
and moderately low in terms of historic archaeological sensitivity. In areas of greater archaeological potential (i.e., on broad terraces or areas near streams and drainages), surface duff and leaf litter accumulation were scraped away to expose soils; such areas were inspected closely for evidence of cultural activity. Two cultural resources, consisting of a rock alignment and an historic debris scatter (archaeological sites and isolates) were documented using Washington State Site-Isolate Forms by CH2M Hill and complied with U.S. Secretary of the Interior Standards.

On October 15, 2003, the proposed staging areas (Figure 2.1-1, Location of Proposed Whistling Ridge energy Project) were surveyed by Dr. James C. Bard and Ms. Carrie Haag of CH2M Hill. A pedestrian survey of these staging areas followed the transect spacing and methodology described above. No cultural resources were observed in the staging areas.

**Traditional Cultural Properties**

No TCPs were identified during the fieldwork for this project, nor have any been identified to date within the study area.

Griffin and Churchill (2001) conducted a thorough TCP investigation for a project directly east of the proposed project area, and east of the White Salmon River. Several categories of TCPs were identified during their study, and examples of these types of TCPs occurred in their study area. TCPs include power sites, wishing sites, vision quest locales, sweat house locations, previous longhouse locations, sacred plant habitats, “refrigerator” storage areas, human burial sites, petroglyph and pictograph sites, and oral tradition and legendary sites. Because the proposed project is located nearby in similar terrain, these same TCP types might be expected to exist in the proposed project area. As noted above, two letters have been received from Chiefs of Tribes of the Yakama Nation, from Chief Wilbur Slockish of the Klickitat Tribe and from Chief Johnny Jackson of the Cascades Tribe. Neither letter identifies any traditional cultural properties or archeological sites within the Project site. Copies of these letters are attached in Appendix F.

**4.2.5.5 Impacts**

**Regulatory Framework**

Federal and state regulations require consideration of project effects on historic and/or cultural resources. Cultural resources must undergo a Section 106 Review Process for projects with a federal nexus under the NHPA. Section 106 review can be included in an EIS as a part of the NEPA compliance documentation.

Under applicable regulations, cultural resources may include:

**Historic Properties.** Historic properties are places eligible for inclusion in the National Register of Historic Places. Historic properties can include districts, sites, buildings, structures, objects, and landscapes significant in American history, prehistory, architecture, archaeology, engineering, and culture. Historic properties include TCPs. Historic properties must be given consideration under NEPA and the NHPA.
Native American Cultural Resources. Native American cultural resources may include human skeletal remains, funerary items, sacred items, and objects of cultural patrimony. Native American cultural items must be given consideration under NEPA, the NHPA, the Native American Graves Protection and Repatriation Act, and the American Indian Religious Freedom Act. Native American sacred sites must be considered under the American Indian Religious Freedom Act and Executive Order 13007. Native American traditional resource procurement areas and culturally important regional landscapes are Native American cultural resources often considered to be traditional cultural properties (and thus potential “historic properties”).

Archaeological Sites. Archaeological sites and other scientific data must be given consideration under NEPA, the Archaeological Resources Protection Act, the Archaeological Data Protection Act, and to some extent under the NHPA and the Native American Graves Protection and Repatriation Act.

Other Cultural Resources. Cultural institutions, lifeways, culturally valued viewsheds, places of cultural association, and other valued places and social institutions must be considered under NEPA, Executive Order 12898, and sometimes other authorities.

“Historic properties” are protected through NHPA (16 USC 470f) and its implementing regulation, Protection of Historic Properties (36 CFR Part 800), the Archaeological and Historic Preservation Act of 1974, and the Archaeological Resources Protection Act. Prior to implementing an “undertaking” (issuing a federal permit), Section 106 of the NHPA requires federal agencies (FHWA, Federal Transit Administration, etc.) to consider the effects of the undertaking on historic properties and to afford the Advisory Council on Historic Preservation and the State Historic Preservation Officer a reasonable opportunity to comment on any undertaking that would adversely affect properties eligible for listing in the National Register of Historic Places. Section 101(d)(6)(A) of the NHPA allows properties of traditional religious and cultural importance to a tribe (TCPs) to be determined eligible for inclusion in the National Register of Historic Places.

Under the NHPA, cultural resources are considered significant if they meet the National Register of Historic Places listing criteria in 36 CFR 60.4. Cultural resources must be evaluated in terms of their overall quality and integrity of location, design, setting, materials, workmanship, feeling, and association. Cultural institutions, lifeways, culturally valued viewsheds, places of cultural association, and other valued places and social institutions also must be considered under NEPA, Executive Order 12898, and sometimes other authorities. The American Indian Religious Freedom Act allows access to sites of religious importance to Native Americans. The Archaeological Resources Protection Act assigns penalties for vandalism and the unauthorized collection of archaeological resources on federal land and provides for federal agencies to issue permits for scientific excavation by qualified archaeologists. The Native American Graves Protection and Repatriation Act assigns ownership of Native American graves found on federal land to their direct descendants or to a culturally affiliated tribe or organization and provides for repatriation of human remains and funerary items to identified Native American descendants.

Cultural Resource Sites – Washington

On August 12-14, 2003, CH2M HILL Cultural Resource Specialists conducted an intensive cultural resource inventory survey of the proposed area of potential effect. Surveyed areas are
shown in Figure 4.2-28 Area of Potential Effects. Ground visibility in the project area varied from 15 percent to nearly 100 percent along turbine string areas, and was consistently 100 percent along proposed roadways and roads proposed for improvement. Soils in the project area are generally thin and characterized by sandy loam with angular and subangular cobbles and gravel inclusions. Occasional boulder outcroppings are present in the project area. Such boulders were inspected for rock art, bedrock mortars, and other evidence of cultural use and modification.

The project area is covered by second and third growth commercial timber stands. Evidence of old growth logging is present in the project area in some locations: springboard notched and tall, large-diameter stumps can be observed in several locations throughout the project area.

No evidence of prehistoric activity was observed during the cultural resource survey. No archaeological sites or historic properties were identified, although two historic archaeological isolates were found and documented.

**Isolate G2A** is a linear stone alignment composed of piled basalt cobbles, all of which could be easily carried without the aid of machinery. No artifacts were found in association with the feature. The function and origin of the alignment are unknown, but the feature is thought to be associated with past logging activities.

**Isolate B** consists of a scatter of historic debris that has been badly disturbed by power transmission line construction, logging, and other development activities in the area. Artifacts from the area include very tiny fragments of purple, brown, olive green, clear, and white glass, two enamel metal cooking tins, a 1-gallon “Union Oil” can with “Triton SAE 30” stamped on the lid; tiny shards of blue on white ceramic, leather fragments, crushed tin cans and can fragments, and a tobacco tin lid. Most of the artifacts were very small and have been fragmented through past construction activity in the area.

**Construction**

No archaeological sites or historic properties were identified in the project area during the field inventory. All previously documented archaeological sites in the project vicinity are located well outside of the project area, as indicated in Table 4.2-8. Both of the archaeological isolates identified during the inventory for this project would likely be affected by the project. However, by definition, these isolates lack integrity and the ability to contribute information important to prehistory or history; they cannot be considered significant cultural resources. Construction of the proposed facilities is not anticipated to result in impacts to known/recorded cultural resources.

It is possible, although unlikely, that there are archaeological sites in the project area that were not detected during the archaeological inventory and fieldwork for this project. Such sites may be encountered during construction, installation, maintenance, and/or repair of the proposed wind energy facility. In the event of such an inadvertent discovery, work would be stopped in the area of the discovery and a qualified archaeologist be summoned to the area to identify and document the find and determine it significance.

TCPs are not known to exist in the project area and no impacts are anticipated.
In the unlikely event of a human remains discovery, federal law requires that all work in the area of the discovery be stopped immediately and the area secured. The Skamania County Medical Examiner would be contacted, and the State Historic Preservation Officer would be notified. If the Medical Examiner determines that the area is not a crime scene, and if the remains are determined to be Native American, the State Historic Preservation Officer and the tribes would consult to arrive at an appropriate treatment plan for the respectful re-internment of the remains.

**Operations**

Operation of the proposed facility would not result in impacts to known cultural resources. However, indirect impacts to cultural resources may result from maintenance activities. For example, maintenance activities for the proposed project facilities may require ground disturbances that could result in inadvertent discovery of cultural resources. If cultural resources are discovered during ground disturbing maintenance activities, assessment of the find would be necessary and appropriate mitigation measures implemented.

**Decommissioning**

Decommissioning of proposed project facilities is expected to result in impacts similar to construction impacts. There is a remote possibility that as-yet unidentified subsurface cultural resources could be discovered inadvertently during decommissioning activities. In this case, the protocol for such a discovery outlined in the Construction Impacts section above should be followed.

**4.2.5.6 Mitigation Measures**

Because no cultural resources (archaeological sites or historic properties) were identified in the project area, no mitigation actions are required. If cultural resources are inadvertently discovered during project construction and operations, assessment of the find would be necessary. If such cultural resources are found to be significant, mitigation measures would need to be devised and implemented.

**4.2.6 AGRICULTURAL CROPS/ANIMALS**

Agricultural activities are those activities conducted on lands defined in RCW 84.34.020(2) Open Space, Agricultural and Timber Lands - Current Use Assessment, and those activities involved in the production of crops and livestock, including but not limited to Operations and Maintenance of existing farm and stock ponds or drainage systems, irrigation systems, changes between agricultural activities, or maintenance or repair of existing serviceable structures and facilities. Activities that significantly impact a previously undisturbed critical area are not part of an on-going activity. An activity ceases to be on-going when the area on which it was conducted has been converted to a non-agricultural use, or has lain fallow for five years.

**4.2.6.1 Existing Conditions**

The Whistling Ridge Energy Project site would be on lands that have been used historically for commercial forestry. The project site has not been used for agricultural crops or animals.
4.2.6.2 Impacts

There would be no impacts to agricultural crops and animals.

4.2.6.3 Mitigation Measures

There would be no impacts to agricultural crops and animals, therefore mitigation measures are not proposed.
SECTION 4.3 TRANSPORTATION  
(WAC 463-60-372)

Construction and operation of the proposed Whistling Ridge Energy Project would affect transportation and traffic in the site area. Transportation issues would include construction traffic on roads (workers, equipment, and material deliveries by truck); transporting large wind energy facility components including tower sections, the nacelle and turbines, and blades either on rail lines or on the Columbia River; and Whistling Ridge Energy operation traffic (employees, visitors, deliveries of materials, and supplies). Types of transportation addressed in this section include roadway, rail, river, and air transport.

4.3.1 EXISTING CONDITIONS

4.3.1.1 Regional and Site Area

The Whistling Ridge Energy Project would be located on private land approximately 7 miles northwest of the city of White Salmon, and approximately 2 miles east of the Little White Salmon River in Skamania County, Washington. The general location is provided on Figure 2.1-1. The project would be located on commercial forest land owned by S.D.S. Co., LLC and Broughton Lumber Company in an unincorporated area of Skamania County, outside of the Columbia River Gorge National Scenic Area. Approximately 2.1 miles of an existing private logging road would traverse the Scenic Area boundary (Figure 4.3-1, Project Site Roadway Network).

Roadway, rail, river, and air transportation are available in the regional and site areas surrounding the Whistling Ridge Energy Project.

Roadway Transportation

Existing Roadways

Access to the proposed Whistling Ridge Energy Project site would be provided by county roads that extend northward from SR 14, as well as an existing private logging road. From SR 14, access would be provided along Cook-Underwood Road to Willard Road, Kollack-Knapp Road, Scoggins Road, and then via a new direct connection to West Pit Road. West Pit Road is an existing private logging road listed as CG2930, that connects to a network of The existing private logging roads is located on S.D.S. Co., LLC and Broughton Lumber Company property, and These logging roads would provide access to most areas where project facilities would be located (Figures 4.3-1 Project Site Roadway Network and 4.3-2 4.3-2a and 4.3-2b, Other Roads with Potential Impact).

Skamania County, Washington
Very little as-built information is available regarding existing pavement and base thickness along the proposed haul route. Field observations were conducted in 2007 and in January and July of 2009, and it was determined that the County roads are generally in good condition with certain sections showing signs of distress. West Pit Road was determined to be generally in poor condition, however roadway improvements for logging purposes were made during the summer of 2009. Additional improvements (beyond those needed for logging operations) will be needed for project construction and operation.

Pavement thickness was determined through measurement of pavement core samples. Roadway sub-grade testing was conducted along the proposed haul route using a dynamic cone penetrometer. Laboratory testing was conducted and in situ sub-grade strength parameters were determined.

**State Route 14.** SR 14 between I-5 and the proposed project site is generally very narrow with 12-foot lanes and 2- to 4-foot paved shoulders. It also has many hills, and curves with tight corners in several places. East of the project site on SR 14, there is one low and very narrow tunnel east of the town of Lyle, and also a very narrow bridge east of the city of The Dalles at approximately MP 86. Between Cook-Underwood Road and SR 97 (Goldendale), SR 14 is generally narrow with 12-foot lanes and 2- to 4-foot paved shoulders. It also has some tight low-recommended-speed corners and a number of hills. Between SR 97 and the junction with SR 395/I-82, SR 14 is generally narrow with 12-foot lanes and 2- to 4-foot paved shoulders.

**Maple Street.** To get from the SDS Lumber Company facility to SR 14, trucks would need to drive on Maple Street for approximately 0.25 mile. This road was recently constructed and is in good condition. Maple Street has two 12-foot lanes, a wide concrete sidewalk on the east side, and a paved shoulder on the west side. This street is under the jurisdiction of the City of Bingen. There are currently no over-size or over-weight load restrictions in force.

**Cook-Underwood Road.** Cook-Underwood Road has two 12-foot lanes and paved shoulders that are 1 foot or less in width. In general, the side slope begins at the fog line. This road is under the jurisdiction of Skamania County. There are currently no over-size or over-weight load restrictions in force.

**Willard Road.** Willard Road has two 12-foot lanes and paved shoulders that are 1 foot or less in width. This road is under the jurisdiction of Skamania County. There are currently no over-size or over-weight load restrictions in force.

**West Pit Road.** West Pit Road varies in width from 20 to 26 feet. It is a dirt road covered in light pit run.

**Kollock-Knapp Road.** Kollock-Knapp Road has two 12-foot lanes and paved shoulders that are 1 foot or less in width. This road is under the jurisdiction of Skamania County. There are currently no over-size or over-weight load restrictions in force.
**Scoggins Road.** Scoggins Road is a narrow road without centerline delineation or useable shoulders. This road is under the jurisdiction of Skamania County. There are currently no oversize or overweight load restrictions in force.

**CG2930:** CG2930 is currently very narrow, approximately 10 to 12 feet wide.

**Existing Traffic Volumes**

Average annual daily traffic (AADT) data for SR 14 was obtained from the WSDOT’s 2006 WSDOT 2008 Annual Traffic Report (WSDOT 2006 2008). AADT on SR 14 at the west junction with Cook-Underwood Road during 2006 2008 was approximately 2,800 3,000 vehicles per day (vpd), and at the east junction with Cook-Underwood Road was approximately 3,300 vpd. A growth rate was developed for the project vicinity using historic data from annual traffic reports between 1996 and 2006 2008. During several years between 1996 and 2006 2008, there was no recorded historical growth in this area. Using this data, an average weighted growth rate of approximately 1 percent per year was determined. Estimated AADT on SR 14 at the west junction with Cook-Underwood Road during 2008 2009 would be approximately 3,000 3,100 vpd, and at the east junction with Cook-Underwood Road would be approximately 3,400 vpd.

Peak hour directional volumes were developed based on typical rural highway traffic patterns and proximity of business centers. Typical rural highway traffic patterns conservatively assume AM peak hour volumes to be approximately 7 percent of the total daily volumes, and PM peak hour volumes to be approximately 10 percent of the total daily volumes, with a directional split of 70/30. PM peak hour volumes are traditionally considered to be the highest during a given day. No current traffic data is available for Cook-Underwood Road at either the west or east junctions with SR 14, and traffic volumes were assumed using good engineering judgment and are based on typical patterns for small rural towns. Estimated 2008 2009 PM peak hour traffic volumes at the junction of SR 14 and Cook-Underwood Road—both the west and the east junctions of Cook-Underwood Road with SR 14—are presented in Table 4.3-1.

**Existing Level of Service**

Level of service (LOS) is an estimate of operational performance based on travel delay to motor vehicles. The *Highway Capacity Manual* (TRB 2000) published by the Transportation Research Board is generally used when determining LOS. The *Highway Capacity Manual* defines LOS using a letter scale from A to F. LOS A is defined as minimal or no delay to vehicles and LOS F is defined as extreme delays to vehicles. LOS criteria for two-way-stop-control intersections are presented in Table 4.3-2.
LOS analyses were conducted for the junction at SR 14 and Cook Underwood Road, both the west and the east junctions of Cook-Underwood Road with SR 14 using Highway Capacity Software Plus (HCS+). HCS+ algorithms are based on *Highway Capacity Manual* (TRB 2000) methodologies.

Analyses indicate that under 2008-2009 estimated traffic volumes, less than up to approximately 10 seconds of delay would be experienced by some vehicles at the junction of SR 14 and Cook Underwood Road, the west junction of Cook-Underwood Road with SR 14. Slightly greater than 10 seconds of delay would be experienced by some vehicles at the east junction of Cook-Underwood Road with SR 14 during the PM peak hour. These delays of approximately 10 seconds would only be expected to occur during the PM peak hour with LOS A operations would be maintained at the west junction and LOS B or better operations at the east junction (Table 4.3-3). LOS C or better is typically considered acceptable for rural intersections and is the LOS threshold for Skamania County.

### Estimated Future Traffic Volumes

The Whistling Ridge Energy Project is scheduled to begin construction during the spring of 2010-2011, and be fully operational by mid-year 2012. Traffic volumes were estimated for these years based on the previously mentioned average weighted growth rate of approximately 1 percent per year. Estimated future traffic volumes without the Whistling Ridge Energy Project are presented in Table 4.3-4.

Estimated Future Level of Service

LOS analyses indicate that the junction of SR 14 and Cook-Underwood Road, both the west and the east junctions of Cook-Underwood Road with SR 14 would continue to operate at LOS A along SR 14 during 2011 and 2012. The southbound approach at the west junction of Cook-Underwood Road with SR 14 would degrade to LOS B during 2011 and would remain at LOS B operations during 2012. On the southbound approach at the east junction of Cook-Underwood Road with SR 14, LOS B operations would be maintained during both future years with no change in LOS over year 2009, but would degrade to LOS B at the Cook Underwood Road approach under both estimated future year scenarios. LOS summaries for estimated future year traffic volumes without the Whistling Ridge Energy Project are presented in Tables 4.3-5.

Delay = Average per vehicle

Rail Transportation

The BNSF Railway operates a rail mainline that runs parallel to SR 14 to the south of the proposed project site. This line is a major link that ties the important industrial areas of Vancouver, BC; Portland, Oregon; and Seattle/Tacoma, Washington to the north-central states of the US, and eastern railroads via Chicago. SDS Lumber Company currently has two rail spurs from the BNSF mainline to their Bingen site. One spur terminates at the Maple Street crossing.
and is approximately 800 feet in length. The second spur terminates at the plywood facility and is approximately 2,000 feet in length.

**River Transportation**

The proposed project site is located north of the Columbia River, which runs predominantly from east to west (and towards the Pacific Ocean) in this part of the state. River transportation in the site area includes barge and boat/shipping transport on the Columbia River. Barges moving upriver from the Ports of Longview or Vancouver are transported to the Bonneville Dam using tug boats. The barges and tugs bypass the Bonneville Dam via the lockage facility, and continue upriver past the SDS Lumber Company facility in Bingen. SDS has a dock and crane suitable for the use of unloading equipment. The Bonneville lockage facility accommodates commercial, government, and recreational vessels. The heaviest lockage traffic on average occurs during the month of August. Vessel traffic is typically heaviest on Thursdays, Fridays, Saturdays, and Sundays.

**Air Transportation**

Air transportation in the regional area includes the Portland International Airport, approximately 60 miles southwest of the proposed project site, and several other public and private local airports within a 10-mile radius.

**4.3.2 IMPACTS**

To determine potential transportation impacts, the Skamania County Public Works Department Manager, the County Engineer, and the Maintenance Superintendent were consulted to better understand existing roadway conditions, the proposed haul route, and traffic patterns. A pre and post over-weight haul design strategy for pavement assessment would be developed for the existing roadway network that would be used for the proposed haul route during construction.

**4.3.2.1 Construction Access Routes**

Construction access to the proposed tower locations would be achieved through travel along SR 14, Cook-Underwood Road, Kollock Knapp Road, Seoggin Road, and CG2930, Willard Road, and West Pit Road. Historically, CG2930 West Pit Road has been used primarily in support of logging activity, and for access to existing BPA transmission lines. Cook-Underwood Road, Kollock Knapp Road, and Seoggin Road and Willard Road are paved Skamania County roadways that extend northward from SR 14, a Washington State roadway, towards the proposed project site. The private logging road listed as CG2930 connects to Seoggin Road and consists of dirt and rock. West Pit Road consists of dirt and rock and extends eastward towards the proposed project site. A new direct connection will be constructed between Willard Road and West Pit Road.

The Skamania County 2007 Comprehensive Plan, Chapter 4, Transportation Element, lists Cook-Underwood Road as Federal Functional Classification “Major Rural Collector” in County District 3. Kollock Knapp Road and Seoggin Road, Willard Road, and West Pit Road are listed as “Rural Local Access” also in County District 3. The Comprehensive Plan Transportation Element was
developed to address transportation needs in Skamania County. It represents the County’s policy plan for the next 20 years and specifically considers the location and condition of the existing traffic circulation system, the projected transportation needs, and plans for addressing future transportation needs while maintaining established level of service standards.

The Southwest Washington Regional Transportation Council is the Regional Transportation Planning Organization for Skamania County, including the cities of Bingen and White Salmon.

All wind energy components including tower sections, the nacelle and turbines, and blades would be shipped to either the Port of Longview or the Port of Vancouver, and then be transported by any or all of the following three modes of travel:

- Specialized trucks along State, County, City, and private roadways
- BNSF rail lines running parallel to SR 14
- Barge and tug boat up the Columbia River and through the lockage facility at the Bonneville Dam

Wind energy components transported on specialized trucks from either of the Ports would be delivered directly to the proposed project site. Components transported either by rail or barge from either of the Ports would be delivered directly to the SDS Lumber Company industrial facility, loaded onto specialized trucks, and then transported to the proposed project site. Fuel would be delivered to the proposed site by truck as needed.

A discussion presenting details for each mode of transport follows.

**Specialized Trucks**

Specialized trucks may be used to transport wind energy components from either the Port of Longview or the Port of Vancouver to the junction of SR 14 and Cook Underwood Road. Trucks transporting wind energy components could have loads as high as 17.5 feet measured from the ground to the highest point of the load, as wide as 14.5 feet or as long as 150 feet. Trucks traveling along SR 14 between Vancouver, Washington and Cook Underwood Road would be physically constrained by a series of three very narrow tunnels with height restrictions as low as 13 feet 9 inches measured vertically from the edge of the roadway (Figure 4.3-3, Tunnel Locations along SR 14). Over-size loads that would include transport of the tower sections, the nacelles and turbines, and blades would encounter restrictions and/or prohibitions along SR 14 between Vancouver, Washington and the west junction of SR 14 and Cook-Underwood Road at MP 63.3256.28 due to the length and/or width of the loads. The WSDOT roadway restrictions that apply to this section of SR 14 are summarized in Table 4.3-6, Road and Bridge Restrictions for Oversize Motor Vehicles on SR 14. Cook-Underwood Road near its northern most point at approximate MP 5.5 contains a bridge that crosses the Little White Salmon River. Crossing this bridge with specialized trucks transporting wind energy components would require special provisions agreed upon between S.D.S Co., LLC and Skamania County.
Figure 4.3-3, Tunnel Locations along SR 14.

<td></td>
</tr>
</tbody>
</table>

An alternate route for transport of wind energy components from either of the Ports to the east junction of SR 14 and Cook-Underwood Road at MP 63.32 would include trucks traveling on I-84 through Oregon to the Boardman junction, then along SR 730 to the junction of I-82 with SR 395, across the Columbia River back into Washington State and then to SR 14. Trucks traveling on SR 14 between the junction of I-82/SR 395 and Cook-Underwood Road would be physically constrained by one very narrow tunnel with a height restriction of 13 feet 3 inches measured vertically from the edge of the roadway.

There are several additional Columbia River crossings west of the I-82/SR 395 crossing, but each has weight restrictions that would prohibit the transport of wind energy components. These crossings include the Bridge of the Gods, the Hood River Bridge, SR 197, and SR 97.

All loads over 10 feet wide traveling from east of the proposed project site between MP 76.77 and 76.91 would require three pilot cars, two in front and one in the rear. The two front pilot cars would be required to maintain a minimum 500-foot separation. The lead pilot car in front of the load would warn oncoming traffic of the over-size load, and the pilot car immediately in front of the over-size load would be responsible to stop all oncoming traffic. All loads over 125 feet in length (including the trailer and load) traveling from east of the proposed project site between MP 83.50 (at the junction of SR 197) and MP 63.32 (at the east junction of SR 14 with Cook-Underwood Road) are prohibited as of October 11, 2007. Special provisions and/or permitting may be required to transport the wind energy blades to the junction of SR 14 and Cook-Underwood Road at MP 63.32 from the junction of SR 197 (MP 83.50) if this route is selected.

1 Heights are measured from the ground to the highest point on the load.
This transport option for wind energy components between either of the Ports and the east junction of SR 14 and Cook-Underwood Road at MP 63.32 from both east and west of the proposed project site may not be physically possible. However, specialized trucks would still be required to transport the wind energy components from the SDS Lumber Company industrial facility in Bingen, Washington to the proposed project site should they be transported on rail or barge from the Port of Longview or Port of Vancouver. Transport of wind energy components using specialized trucks from the SDS Lumber Company industrial facility to the east junction of SR 14 and Cook-Underwood Road at MP 63.32 would require the use of SR 14, which has a restriction on loads over 125 feet in length.

**Rail**

The option of using rail to transport the wind energy components from the Port of Longview to the SDS Lumber Company industrial facility also was analyzed. Wind energy components on rail cars can be up to 14.5 feet in width, up to approximately 15 feet in height, and as long as 150 feet. The BNSF rail line between Vancouver, Washington and the SDS Lumber Company facility in Bingen, Washington may not be able to accommodate loads with widths in excess of 14 feet. This may preclude transport of the bottom tower sections using rail. The wind energy nacelles, turbines, and blades could be transported along the BNSF line to the SDS Lumber Company facility. BNSF could transport the wind energy components on standard or heavy-duty 89-foot long flat rail cars. The wind energy components would be off-loaded at the SDS Lumber Company facility to a staging location to be determined and loaded onto specialized trucks for transport to the proposed project site. Transport of wind energy components using specialized trucks from the SDS Lumber Company industrial facility to SR 14 would require the use of Maple Street in the City of Bingen, Washington for approximately 0.25 mile. There are currently no over-size or over-weight restrictions for this roadway. Transport of the wind energy blades from the SDS Lumber Company industrial facility to the east junction of SR 14 and Cook-Underwood Road at MP 63.32 would require the use of SR 14, which has a restriction on loads over 125 feet in length.

**Barge**

The third option analyzed for transporting the wind energy components from either the Port of Longview or Port of Vancouver to the SDS Lumber Company industrial facility was by using barges. The wind energy components would be off-loaded from a ship at either of the Ports, loaded onto barges, and then transported upriver to the Bonneville Dam using tug boats. The barges and tugs would by-pass the Bonneville Dam via the lockage facility, and continue upriver to the SDS Lumber Company industrial facility. There would be no over-size or over-weight restrictions using barges as a transport mode for wind energy components at either of the Ports, on the Columbia River, or at the lockage facility at the Bonneville Dam. Coordination with the Bonneville Dam Project Office would be required to determine optimal times for lockage use. The Bonneville lockage facility accommodates commercial, government, and recreational vessels. The heaviest lockage traffic on average occurs during the month of August. Vessel
traffic is typically heaviest on Thursdays, Fridays, Saturdays, and Sundays. The wind energy components would be off-loaded at the SDS Lumber Company industrial facility to a staging location to be determined and loaded onto specialized trucks for transport to the proposed project site. Transport of wind energy components using specialized trucks from the SDS Lumber Company facility to SR 14 would require the use of Maple Street in the City of Bingen, Washington for approximately 0.25 mile. There are currently no over-size or over-weight restrictions for this roadway. Like the use of rail, this option would still require using specialized trucks to transport the wind energy blades from the SDS Lumber Company facility to the east junction of SR 14 and Cook-Underwood Road at MP 63.32, and this section of SR 14 has a length restriction of 125 feet.

4.3.2.2 Roadway Improvements

Improvements to the County roadways and the private logging road would be necessary to support the long and heavy loads that would be required for the delivery of the wind energy components from SR 14 to the proposed project site. Improvements required for support of construction activities would depend primarily upon truck size, load size, and axle loading. Roadway improvements could include:

- Rebuilding large sections of the existing roadway network
- Widening certain sections of the existing roadway network
- Flattening and/or rebuilding existing roadway topography both horizontally and vertically
- Placing asphalt in select areas for hauling equipment access

A detailed discussion of specific roadway improvements for each roadway along the haul route follows. All private roadway improvements required prior to hauling and new private roadway construction at the proposed project site would be designed and constructed in accordance with the standards for the applicable road classifications as set forth in the Skamania County Private Road Guidelines and Development Assistance Manual, as adopted by the County Resolution in 2008. All existing county roadways requiring improvements prior to hauling would be designed and constructed in accordance with the WSDOT Design Manual (WSDOT 2007) and A Policy on Geometric Design of Highways and Streets (AASHTO 2004).

State Route 14. All over-size and over-weight loads would require permits. These loads also would require pilot cars both in the front and the rear, and could require additional traffic control measures. SR 14 would require no improvements to accommodate the transport of wind energy components, except possibly for the need for minor improvements at the intersection of SR 14 and Cook-Underwood Road.

Maple Street. To get from the SDS Lumber Company facility to SR 14, trucks would need to drive on Maple Street for approximately 0.25 mile. This road was recently constructed and is in good condition. Maple Street has two 12-foot lanes, a wide concrete sidewalk on the east side, and a paved shoulder on the west side. There are currently no over-size or over-weight load
restrictions in force and permitting by the City of Bingen would not be required. These loads would require pilot cars both in the front and the rear and could require additional traffic control measures. Maple Street would require no improvements to accommodate the transport of wind energy components.

**Cook-Underwood Road.** Cook-Underwood Road has two 12-foot lanes and paved shoulders that are 1 foot or less in width. There are currently no over-size or over-weight load restrictions in force but permitting would be required by Skamania County. These loads would require pilot cars both in the front and the rear and could require additional traffic control measures. Cook-Underwood Road would require no improvements to accommodate the transport of wind energy components outside the limits of the junction with SR 14 and the intersection with Kollock-Knapp Road.

At the junction with SR 14, improvements would be required. Specialized trucks (including a drivable rear axle) transporting wind energy blades (which are the longest single wind energy component) westbound on SR 14 onto Cook-Underwood Road at MP 56.28 or westbound onto Cook-Underwood Road at MP 63.32 would require a 135-foot inside turning radius, and a 20-foot allowance for “tip swing.” Approximately 15 to 20 feet of the wind energy blade would extend beyond the centerline of the drivable rear axle.

At the intersection of Cook-Underwood Road and Kollock-Knapp Road (Figure 4.3-8), improvements would be required for transport of wind energy blades to the proposed project site. To accommodate the required truck turning radii, temporary widening at this intersection would be required. Widening would include removal of trees and vegetation and embankment cut sections both on the inside and outside of the turn. The embankment cut sections would not require paving, but would require an all-weather driving surface. Right of way ownership and easement determination would be required.

At the intersection of Cook-Underwood Road and Willard Road improvements could be required for transport of wind energy blades to the proposed project site for trucks coming from the west. To accommodate the required truck turning radii, temporary widening at this intersection could be required. Widening could include removal of trees and vegetation, and engineered fill sections and embankment cut sections. The engineered fill and embankment cut sections would not require paving, but would require an all-weather driving surface. Right of way ownership and easement determination would be required.

**Willard Road.** Willard Road has two 12-foot lanes and paved shoulders that are 1 foot or less in width. In general, the side slope begins at the fog line. There are currently no over-size or over-weight load restrictions in force but permitting would be required by Skamania County. These loads also would require pilot cars both in the front and the rear and could require additional traffic control measures. Willard Road would require no improvements to accommodate the transport of wind energy components outside the limits of the intersection with Cook-Underwood Road.

A new direct connection would be required between Willard Road and West Pit Road for transport of wind energy blades to the proposed project site. The intersection of Willard Road and West Pit Road would be designed to accommodate the required truck turning radii.
West Pit Road. West Pit Road varies in width from 20 to 26 feet. It is a dirt road covered in light pit run. This road would require additional permanent widening to accommodate transport of wind energy components from Willard Road to the proposed project site. West Pit Road would be improved to provide a minimum drivable section width of 25 feet (width of finished road), with an additional 5 feet of shoulder on either side to provide access to the site by construction vehicles, with allowance for side slope and drainage. Widening could include removal of trees and vegetation, and engineered fill sections and embankment cut sections. The engineered fill and embankment cut sections would not require paving, but would require an all-weather driving surface.

Kollock-Knapp Road. Kollock-Knapp Road has two 12-foot lanes and paved shoulders that are 1 foot or less in width (Figures 4.3-9 through 4.3-12). In general, the side slope begins at the fog line. There are currently no over-size or over-weight load restrictions in force but permitting would be required by Skamania County. These loads also would require pilot cars both in the front and the rear and could require additional traffic control measures. Kollock-Knapp Road would require no improvements to accommodate the transport of wind energy components outside the limits of the intersections with Cook-Underwood Road and Scoggins Road.

At the intersection of Kollock-Knapp Road and Scoggins Road (Figures 4.3-13 and 4.3-14), improvements would be required for transport of wind energy blades to the proposed project site. To accommodate the required truck turning radii, temporary widening at this intersection would be required. Widening would include removal of trees, vegetation, and fencing as well as an engineered fill and embankment cut section on the outside of the turn; and removal of vegetation and shrubs and an embankment cut section on the inside of the turn. The engineered fill and embankment cut sections would not require paving, but would require an all-weather driving surface. Right of way ownership and easement determination would be required.

Scoggins Road. Scoggins Road is a narrow road without centerline delineation or useable shoulders. In general, the side slope begins at the fog line (Figure 4.3-15). Approximately 150 to 200 feet of Scoggins Road would be required for use for construction and operational purposes. There are currently no over-size or over-weight load restrictions in force but permitting would be required by Skamania County. These loads also would require pilot cars both in the front and the rear and could require additional traffic control measures. Scoggins Road would require no improvements to accommodate the transport of wind energy components outside the limits of the intersections with Kollock-Knapp Road and CG2930.

At the intersection of Scoggins Road and CG2930, improvements would be required for transport of wind energy blades to the proposed project site. To accommodate the required truck turning radii, temporary widening at this intersection would be required. Widening would include removal of trees and vegetation and an embankment cut section on the inside of the turn, and removal of trees and vegetation and an engineered fill section on the outside of the turn (Figure 4.3-16). Improvements to the intersections of Scoggins Road with both Kollock-Knapp Road and CG2930 would most likely encroach upon the entire length of Scoggins Road proposed for the haul route to the proposed project site. The engineered fill and embankment cut sections would not require paving, but would require an all weather driving surface. Right of way ownership and easement determination would be required.
CG2930. CG2930 is currently very narrow, approximately 10 to 12 feet wide, and would require permanent widening to a minimum drivable section width of 20 feet with allowance for side slope and drainage from Scoggins Road to the proposed project site (Figures 4.3-17 through 4.3-25). Widening would require possible removal of trees, and possible engineered fill and embankment cut sections. The engineered fill and embankment cut sections would not require paving, but would require an all-weather driving surface. There are two sharp left hand turns in the roadway enroute to the proposed project site (Figures 4.3-17, 4.3-23, and 4.3-24) that would require additional special considerations to accommodate the required truck turning radii for transport of the wind energy blades to the site.

New Roadway Construction at the Proposed Project Site

Access to the proposed project site would be provided through the existing County and private roadway network. Access to all proposed wind tower locations would require some new road construction. In addition to approximately 7.2-7.9 miles of existing private logging roads that would require improvement, approximately 2.4 miles of new private gravel access roads would need to be constructed. The new gravel roadways would extend toward and run along the turbine strings, and would be designed and constructed according to the County private roadway standards. The new private roadways that extend toward the turbine strings would be designed for a minimum drivable section width of 25 feet with allowance for side slope and drainage. The new private roadways that would run along or between the turbine strings would be designed for a minimum drivable section width of 25 feet with an additional 5-foot section on both sides to accommodate drainage and clearance for the project crane that would be on site to assemble the
tower sections, the nacelles, and blades. Not all newly constructed roads would need to be paved, but they would require an all-weather driving surface.

**Roadway Limitations**

Some of the trucks that would transport construction equipment and materials to the proposed project site along State and County roadways could have a gross vehicle weight in excess of 105,500 pounds. These loads would exceed the WSDOT legal load limit. Trucks with loads in excess of the legal load limit could degrade the condition of the existing roadways along the proposed haul route, and may require additional axles in order to distribute the weight of the load. Permits would be required for all over-weight hauls.

**Parking**

During construction, parking would be located at the construction staging area and along the proposed project site access roads. Parking along turbine string roads would be primarily for those employees working on foundations, electrical infrastructure, and turbines. Vehicles would park in areas that would be already temporarily or permanently disturbed from other construction activities. No additional ground disturbance would occur solely for construction parking requirements.

**Hazardous Materials Transport**

Diesel fuel and gasoline would be the only potentially dangerous materials that would be used in significant quantities during construction. The estimated total quantity delivered and consumed during construction would be approximately 19,250 gallons. The contractor would use fuel trucks to refill construction vehicles and equipment on site. The fuel trucks would be properly licensed and would incorporate features in equipment and operation such as automatic shut-off devices to prevent accidental spills.

**Aviation Hazards**

Temporary construction equipment such as cranes and derricks that would be used for the construction of the proposed towers could propose a hazard to aviation safety during the construction period. A “Determination of No Hazard to Air Navigation” would have to be obtained for the proposed project site.

**Traffic Hazards**

Traffic hazards associated with construction projects are generally related to accident occurrence. Construction of the project would require that many construction vehicles, including trucks with over-size and over-weight loads, share the existing roadway network with the general public. As a result, some accidents could occur that would be directly attributable to construction traffic. An increase in accident occurrence during the construction of the project could take place, but any increase is expected to be minimal.
4.3.2.3 Construction Traffic

The project construction activities would last approximately one year, and would continue from site preparation through full operation. During that time frame, there would be an increase in traffic activity in and around the proposed project vicinity due to the construction workforce, equipment deliveries, and empty trucks returning to SR 14. Traffic delays could occur on the existing roadway network due to the maneuvering of large vehicles carrying heavy and/or long loads.

During the summer months, the cities of Bingen and White Salmon experience a significant increase in traffic volume due to recreational activities in the surrounding area. Prior to construction of the Whistling Ridge Energy Project, coordination would be required between the owner, contractor, the cities of Bingen and White Salmon, Skamania County, and WSDOT to ensure the highest level of safety possible for both the traveling public and the construction vehicles.

During construction, approximately 330 workers total would be employed. During the peak construction period, it is expected that approximately 265 personnel would be on site at the same time, while multiple construction disciplines conduct work concurrently. Estimated traffic volumes include existing local traffic, construction workers and vehicles, and over-size and over-weight trucks. Approximately 65 to 75 percent of the construction labor force would most likely be hired from the cities of Portland and Vancouver. Approximately 25 to 35 percent of the workers would most likely be residents of Skamania, Klickitat, and Hood River counties. The respective percentages are based on the relative populations in the cities of Portland and Vancouver when compared to Skamania, Klickitat, and Hood River counties. All construction workers are expected to commute up to approximately 60 miles each way daily to and from the proposed project site.

Estimated traffic volumes during construction of the Whistling Ridge Energy Project at the west and east junctions of Cook-Underwood Road with SR 14 are presented in Table 4.3-7.

During the one-year construction period, there would be over-size and over-weight trucks transporting large wind energy components to the proposed project site throughout the day. Over-size and over-weight trucks are only expected during an approximate two to three month period when the wind energy components are transported to the proposed project site. For traffic analyses purposes, two worst case scenarios were considered. The first assumes that all construction vehicles related to the project during construction would travel through the west junction of Cook-Underwood Road with SR 14. The second assumes that all construction vehicles related to the project during construction would travel through the east junction of...
Cook-Underwood Road with SR 14. The respective numbers of construction vehicles related to the project during construction that would travel through either the west or the east junctions of Cook-Underwood Road with SR 14 is not known at this time. It is expected though that during the AM peak hour, approximately 30 construction vehicles would travel through either junction of SR 14 and Cook-Underwood Road. During the PM peak hour, as many as 10 construction vehicles could travel through this junction. Typical rural highway traffic patterns conservatively assume AM peak hour volumes to be approximately 7 percent of the total daily volumes, and PM peak hour volumes to be approximately 10 percent of the total daily volumes, with a directional split of 70/30. PM peak hour volumes are traditionally considered to be the highest during a given day. A “worst case” traffic analysis scenario is presented for the AM and PM peak hours and includes 7 and 10 percent of the total daily construction vehicles, respectively.

4.3.2.4 Roadway Operations during Construction

Peak-hour LOS analyses were completed for both the west and east junctions of SR 14 and Cook-Underwood Road using estimated 2010 _2011_ traffic volumes. The results indicate that estimated 2010 _2011_ traffic volumes including construction vehicles would have a minimal impact on the operations of either the west or east junction of SR 14 and Cook-Underwood Road. Delays would increase slightly (up to approximately 4 to 5.6 seconds per vehicle) for vehicles turning left or right from Cook-Underwood Road at either the west or the east junctions of Cook-Underwood Road with SR 14 over estimated 2008 _2011_ operations. The southbound approach on Cook-Underwood Road at the west junction with SR 14 also would experience degradation in LOS from A to B during the AM hour over estimated 2008 _2011_ operations. The southbound approach on Cook-Underwood Road at the east junction with SR 14 would experience degradation in LOS from B to C during the AM peak hour over estimated 2011 operations. LOS B operations would be maintained at both the west and east junctions of Cook-Underwood Road with SR 14 during the PM peak hour with no change in LOS over year 2011. Analyses results are presented in Tables 4.3-8 and 4.3-8a.

### Operational Traffic

The project is being designed to operate continuously (24 hours a day, seven days a week) using an automated system. The project would employ an estimated eight to nine full-time employees. The operations crew would typically work eight-hour days Monday through Friday.

The maximum number of vehicle trips associated with workers commuting to and from the proposed Operations and Maintenance facility on State, County, and private roads would be approximately 30 daily. In addition to the operations crew, there would be occasional service delivery vehicle trips as well. The distribution of operational traffic trips is expected to be the same as for construction trips.

Peak-hour traffic volumes at both the west and east junctions of SR 14 and Cook-Underwood Road include 2011 baseline traffic volumes and the project-generated traffic volumes. For traffic analyses purposes, two worst case scenarios were considered. The first assumes that all operational vehicles related to the project during operation would travel through the west junction of Cook-Underwood Road with SR 14. The second assumes that all operational

### River and Air Transportation

Anticipated impacts to river transportation would be low. It is not expected that local or regional airports would be used for transporting construction equipment or material and no air transportation impacts would be anticipated.
vehicles related to the project during operations would travel through the east junction of Cook-
Underwood Road with SR 14. The respective numbers of operational vehicles related to the
project during operations that would travel through either the west or the east junctions of Cook-
Underwood Road with SR 14 is not known at this time. Estimated traffic volumes during full
operation of the project are presented in Table 4.3-9.

Peak-hour LOS analyses were completed for both the west and east junctions of SR 14 and
Cook-Underwood Road—both the west and east junctions of Cook-Underwood Road with SR 14
using estimated 2011 2012 traffic volumes. The results indicate that estimated 2011 2012 traffic
volumes, including operational vehicles, would have a minimal impact on the operations of the
junction of SR 14 and Cook-Underwood Road, either the west or the east junctions of Cook-
Underwood Road with SR 14. Delays would increase slightly, less than 1 second per vehicle,
for vehicles turning left or right from Cook-Underwood Road at either the west or the east
junctions of Cook-Underwood Road with SR 14. The southbound approach on Cook-Underwood Road at SR 14 also would experience degradation in
LOS from A to B over estimated 2008 operations, but only during the PM peak hour. LOS A
and B operations would be maintained during the AM and PM peak hours respectively at both
the west and east junctions of Cook-Underwood Road with SR 14 with no change in LOS over
year 2012. Analyses results are presented in Tables 4.3-10 and 4.3-10a.

### Roadway Limitations

Vehicles used during Operations and Maintenance of the proposed project would primarily consist of employees commuting to and from the site. This number is not expected to exceed State or County roadway legal load limits. These vehicles would not contribute to roadway degradation.

### Parking

During operations, employees would park at the Operations and Maintenance facility parking lot. There would be a maximum of approximately 10 employee vehicles each day as well as potential visitor and delivery vehicles. No more than approximately 20 vehicles are expected to be parked in the Operations and Maintenance facility parking lot at any one time. A visitor kiosk is also planned at the Operations and Maintenance facility that would provide tourists with a safe place to view and learn about wind turbines. Parking requirements for the visitor kiosk would be accommodated by the Operations and Maintenance facility parking lot.

### Hazardous Materials Transport

No significant quantities of hazardous materials would be transported to or from the proposed project site during operations. The only hazardous materials that would be transported to the site would include minimal quantities of lubricating oils, hydraulic fluids, and mineral oil. Hazardous waste materials would require infrequent disposal and would not result in safety risks associated with hazardous materials transport.

### Aviation Hazards

It is expected that the proposed wind turbines would not be in conflict with arriving or departing aircraft under instrument flight rule or visual flight rule from either the public or private airports within the proposed project vicinity. The FAA would need to be notified of any alterations to the wind towers that could affect the national air space. All towers would meet FAA regulations regarding lighting. A “Determination of No Hazard to Air Navigation” would be obtained for the proposed project site.

### Traffic Hazards

Operation of the project is not expected to increase traffic hazards related to accident occurrences.
4.3.3 MITIGATION MEASURES

Construction Traffic Control

The following mitigation measures are proposed to reduce impacts from project construction on roadway traffic in the region:

- A Transportation Management Plan (TMP) would be prepared in consultation with both WSDOT and Skamania County and submitted to EFSEC for approval that would direct and obligate the contractor to implement procedures to minimize traffic impacts

- The TMP would include requirements for coordination of project-related construction traffic and WSDOT planned construction projects

- The TMP would include requirements for coordination of project-related construction traffic and Skamania County, City of Bingen, and City of White Salmon summer recreational traffic

- Whistling Ridge Energy LLC and its contractors would be required to comply with State and County permitting requirements for over-size and over-weight vehicles

- Whistling Ridge Energy LLC would be required to notify land owners in the project vicinity prior to construction of transportation routes that would be used for construction equipment and labor

- Approved State and/or County advanced warning construction signs would be placed prior to and during construction

- Certified flaggers would be used when necessary to direct traffic when over-size and over-weight trucks either enter or exit public roads, to minimize risk of accidents

- Pilot cars would be used both in front of and behind all trucks transporting over-size or over-weight loads on all public roadways

- Traffic flow would not be restricted for more than 20 minutes during the construction phase

Access Roadway Construction

All sections of the access roadway system that would require improvements or new construction would be designed and built according to WSDOT and Washington State access management standards.
Hazardous Materials Transport

Transport of hazardous materials would be conducted in a manner that would protect both human health and the environment and would be in accordance with applicable Federal and WSDOT requirements.

Roadway Maintenance

- Pre- and post-haul construction visual assessments of roadway surface conditions would be conducted identifying weak or deteriorated areas along the haul route that may require mitigation.

- Should mitigation be required, a mitigation design program would be developed to repair all pavement sections to pre-construction conditions or better.

- Whistling Ridge Energy LLC would be responsible for maintaining turbine string access roads, access ways, and other roads built to construct and operate the proposed project.

- All snow removal would be performed in a safe manner that would not degrade roadway conditions.
SECTION 4.4 SOCIOECONOMIC IMPACT
(WAC 463-60-535)

This section presents an analysis of the impact of the Whistling Ridge Energy Project on local socioeconomic resources. The section analyzes impacts to local population, work force, property values, housing, the local economy, government fiscal conditions, health and safety facilities and services, and education facilities and services. An analysis of the impacts the project would have on traffic is contained in Section 4.3, Transportation.

4.4.1. EXISTING CONDITIONS

The project site is located in unincorporated Skamania County in southwestern Washington, approximately 7 miles northwest of White Salmon, Washington and Hood River, Oregon. The area for which information is presented includes Skamania, Klickitat, and Hood River counties, and the cities of White Salmon and Hood River, depending on the resource and the available data for that resource. Data for the State of Washington are presented for comparison.

4.4.1.1 Population and Housing

Demographic Characteristics

The population of Skamania County in 2008 was 10,700 and represented less than one percent of the statewide population of 6.6 million. Table 4.4-1 presents the geographic distribution of the population within Skamania County, compared to the State of Washington. As shown, a greater percentage of Skamania County residents live in unincorporated areas (78 percent) than in incorporated cities. Within the incorporated area, 62 percent of the population lives in Stevenson and the remaining 38 percent lives in North Bonneville. The populations of the cities of Stevenson and North Bonneville represent 13 percent and 8 percent of the total County population, respectively. The counties of Klickitat, Washington, and Hood River, Oregon, have slightly fewer residents living in unincorporated areas relative to Skamania County.

Incorporated cities closest to the project site are the City of White Salmon (7 miles southwest of the site) in Washington and the City of Hood River (approximately 8 miles southwest of the site) in Oregon. The City of Hood River is home to 6,865 residents, while the City of White Salmon is home to 2,205 residents. The metropolitan area closest to the project site is the Portland-Vancouver-Beaverton metropolitan area, with a population of 2.2 million people (PSU Research Center 2008a), located approximately 61 miles west of the project site.

Table 4.4-2 shows the age distributions of the residents of the cities of White Salmon and Hood River; the counties of Skamania, Klickitat, and Hood River; and the states of Washington and Oregon for 2008. Age distribution illustrates the ratio of working-age persons to younger and older residents, which affects both the supply of labor and the level and distribution of income. In White Salmon, 36 percent of the population is of non-working age (i.e., either 14 or under, or 65 and over). In Skamania County and Klickitat County, 22 percent and 24 percent of the populations (respectively) are of non-working age. In comparison, the same measures for the Washington and Oregon are 22 percent and 21 percent.

Table 4.4-3 shows that the cities of White Salmon and Hood River have slightly more women than men, and are predominantly white and non-Hispanic racially, although minority residents represent 23 percent of the White Salmon population and 31 percent of the Hood River population. The three-county area including Skamania, Klickitat, and Hood River counties is also predominantly white, non-Hispanic. Hood River County has the highest minority percentage (31 percent) of population, followed by Klickitat County (16 percent) and Skamania County (11 percent). The State of Washington population includes 24 percent minority residents. Oregon’s population is 20 percent minority.

Source: Claritas (2009).

a. For the purpose of this analysis, minority includes those residents identified as Black or African American, American Indian or Alaskan Native, Asian Pacific Islander, Some Other Race, Two or More Races, or Hispanic/Latino.

Notes:
Percentages may not total 100 percent due to decimal places not expressed in this table.
AIAN = American Indian or Alaskan Native
API = Asian Pacific Islander
SOR = Some Other Race or Two or More Races
CBG = Census Block Group
CT = Census Tract
The race and ethnicity composition of the project area is estimated by analyzing the three census block groups that most closely match an area defined by a three-mile radius around the project site. When combined, the population in these three census blocks is approximately 12 percent minority. The second most common race and ethnicity category for residents in this area is (1) Hispanic/Latino, and (2) Some Other Race or Two or More Races.

The population living within three miles of the project site has a lower minority percentage than the two nearest cities (White Salmon and Hood River), Klickitat County, Hood River County, Washington State, and Oregon State. The population within three miles of the project site has a higher minority percentage (12 percent) compared to the same measure for Skamania County as a whole (11 percent). Although minority residents do exist near the project site, the area near the project does not have a substantially higher minority population when compared to larger reference populations.

Poverty status in 2000 is available for all areas studied. More current poverty statistics (for the period 2005 to 2007 as an annual average) are only available for the areas with relatively larger populations (Klickitat County, Hood River County, Washington, and Oregon). Table 4.4-4 shows 2000 poverty statistics for all areas (for comparison purposes), and also shows more current poverty statistics where available. Poverty estimates for 2008 were not available.

</table>

a. Estimates of this type of data for the areas with smaller populations (census block groups, cities, and Skamania County) were not available for more recent years from the US Census or from Claritas.

b. Poverty status was determined by dividing the population living below poverty by the population for whom poverty status is determined, which excludes those living in institutional housing.

In 2000, 17 percent of the populations of the cities of White Salmon and Hood River were living below the poverty level. This same measure was 13 percent for Skamania County, 17 percent
for Klickitat County, and 14 percent for Hood River County the same year. The cities and counties near the project site had relatively more residents living below the poverty level compared to Washington as a whole, and Oregon as a whole in 2000.

Approximately nine percent of the population living within approximately three miles of the project site lived below the poverty level in 2000, indicating fewer people living in poverty compared to the cities and counties near the project site. The geographic areas for which more recent (2005–2007 annual average) poverty statistics are available have all increased in percentage of persons living below the poverty level, as shown in Table 4.4-4.

### Population Growth Trends

Most of the population in Skamania County lies in the southern quarter of the county, along the Columbia River and in the Wind River Valley. Population growth in Skamania County was 0.4 percentage points less than the State of Washington during the period 2000 to 2008, but is expected to approach the state rate during the period 2008 to 2015. Skamania County’s population is expected to grow from 10,700 in 2008 to 11,720 in 2015. Both Skamania County and Washington State growth rates are expected to slow by 0.3 percentages points during the period 2015 to 2025. Skamania County is expected to have 12,915 residents by 2025 (Table 4.4-5).

The City of White Salmon, near the project but in Klickitat County, has decreased in population 1.1 percent per year, on average, between 2000 and 2008, from 2,193 in 2000 to 2,005 in 2008. The City of Hood River has grown 2.1 percent per year between 2000 and 2008, from 5,831 in 2000 to 6,865 in 2008. During the same period, Hood River County grew 0.7 percent annually, from 20,411 in 2000 to 21,625 in 2008. Hood River County is expected to grow 1.2 percent and 1.3 percent, respectively, during the periods 2008–2015 and 2015–2025. Although Hood River County’s growth
rate for the period 2000–2008 was over one-half of one percent less than the same measure for Oregon State, in future periods 2008–2015 and 2015–2025, the growth rate for Hood River County is expected to be 0.1 percentage point higher than the same measure for Oregon (Table 4.4-5).

**Housing Characteristics**

Table 4.4-6 presents housing characteristics in Skamania County, Klickitat County, Hood River County, the cities of White Salmon and Hood River, and the states of Washington and Oregon. The number of housing units that existed in Skamania County in 2000 (4,576) increased to 5,409 by 2008, representing an annual average rate of growth of 2.1 percent, a rate that is slightly higher than the same rates for Klickitat County (1.8 percent) and the state (1.7 percent).

Sources include 2005-2007 estimates for geographic areas with over 20,000 population (US Census 2008a), 2000 estimates (US Census 2008b), and 2008 information from Washington Office of Financial Management (WOFM 2008d), except where footnoted.

The rate of increase in number of housing units for Hood River County and Oregon State are 1.0 percent and 1.3 percent, respectively, for the period 2000 to 2008. Occupancy rates increased in Skamania County and Klickitat County during the period 2000 to 2008, and decreased for Washington State and Hood River County. Occupancy rates in Oregon stayed constant during the period 2000 to 2008. During that same period, the share of occupied units that were owner-occupied increased in Skamania County, Washington State, and Oregon State, and decreased in Klickitat County and Hood River County.

Between 2000 and 2008, the population of Skamania County grew by approximately 1.0 percent per year, while the number of housing units in the county was expected to grow by 2.1 percent.

Whistling Ridge Energy Project
EFSEC Application 2009-01

4.4-6 March 10, 2009
These measures suggest that vacancy rates have increased during this period, indicating decreasing demand for housing. Average household size in Skamania County was 2.6 people, slightly higher than the same measure for Washington State during the period 2000 to 2008 (Table 4.4-6).

The number of housing units in the cities of White Salmon and Hood River increased during the period 2000 to 2008 by 0.5 percent (White Salmon) and 1.8 percent (Hood River). Occupancy rates in 2008 were 93.8 percent (White Salmon) and 88.2 percent (Hood River). Household sizes for these cities were similar to the same measures for the counties in which they are located. Over half of occupied housing units were owner-occupied in White Salmon in 2008, while slightly less than half of occupied housing units were owner-occupied in Hood River in 2008 (Table 4.4-6).

In 2000, median gross rent was 13 percent lower in Skamania County when compared to the state. In Klickitat County the same year, median gross rent was 25 percent lower when compared to the same statistic for Washington State. Median gross rent in White Salmon in 2000 was slightly higher when compared to the same measure for Klickitat County. During the period 2000 to 2007, median gross rents grew approximately 2.5 percent in Klickitat County and 3.2 percent in Washington State.

The City of Hood River, the largest city in the project vicinity, is located across the Columbia River from the project site. The City of Hood River had median gross rent of $544 in 2000. That year, rents were higher when compared to Hood River County. Median gross rent in Hood River County was 13 percent lower than in Oregon as a whole in 2000. More currently, during the period 2005–2007, rents in Hood River County were lower compared to Oregon.

Housing values in Skamania and Klickitat counties were lower in 2008 when compared to some other areas in Washington State (Table 4.4-7). The median housing value in the City of White Salmon ($192,750) was higher than in Klickitat County as a whole. The median housing value for the City of Hood River in 2008 ($199,215) was less than the same measures for Hood River County ($213,173) and Oregon ($236,157) (Table 4.4-7).

The residences closest to the project site are located approximately 0.48 mile and 0.8 mile from proposed turbine locations. A new homesite location has been applied for, and would be located approximately 2,000 feet (0.38 mile) from the south property line. The unincorporated community of Willard is located approximately 2.25 miles northwest of the project site. The unincorporated community of Mill also A is located near the project site, approximately 1.5 miles west of the site. The homes near the project site are rural, primarily single family, between 30 and 50 years old, and low- to medium-density.

### 4.4.1.2 Employment and Income

The sources of income and types of employment in an area often provide the most comprehensive indicators of the health and direction of the local economy. To a large extent, these factors also play a part in determining the overall welfare and quality of life of the individuals inhabiting the area. Tables 4.4-9 through 4.4-11 present 2006 income and employment levels for Skamania County, Klickitat County, and Hood River County.

In 2006, employment in Skamania County averaged 3,116 jobs, of which 2,284 (73 percent) were held by wage and salary workers and 832 (27 percent) by proprietors. Place of work earnings (wages, salaries and proprietors’ earnings) accounted for approximately one-quarter of total personal income in the county, with income from property (dividends, interest and rent) and transfer payments (mainly Social Security) making up the balance. The principal sources of employment were local government, accommodation and food services, federal government, and manufacturing (Table 4.4-9).

Source: BEA 2008.
This type of industry breakdown is not available for years beyond 2006.
(D) Not shown to avoid disclosure of confidential information; estimates for this item are included in the totals.
NA = Not available

The annual unemployment rate in Skamania County was 6.6 percent in 2007, and rose to 8.4 percent in 2008. In comparison, the same measure in 2000 was 6.0 percent. Relative to the state as a whole, Washington unemployment rates in 2007 and 2008 were 4.5 percent and 5.5 percent, respectively, having risen from 5.0 percent in 2000 (Table 4.4-12) (WESD 2008). Per capita personal income in 2006 in Skamania County was $28,265, which was 74 of per capita personal income for the State of Washington as a whole (BEA 2008). Median household income the same year (2006) was $39,476, or 70 percent of the same measure for Washington State as a whole ($56,184) (WOFM 2008e). These statistics indicate relatively lower income near the project when compared to some other areas in Washington.

These current unemployment rates and trends and income levels not only reflect that the economy in Skamania County is more depressed when compared to some other areas in Washington, but also that the current national economic slowdown that began in 2008 is affecting areas near the project. The 2008 annual unemployment rate in Skamania County was almost three percentage points higher than the state average, indicating a slow economy.

NA = Not available

To the east of the project, 6,573 jobs (67 percent) of the total 9,880 jobs in Klickitat County in 2006 were held by wage and salary workers. Approximately 33 percent of jobs (3,307 jobs) were held by proprietors. Place of work earnings (wages, salaries and proprietors’ earnings) accounted for about 46 percent of total personal income in the county, with income from property (dividends, interest and rent) and transfer payments (mainly Social Security) making up the balance. The principal sources of employment were local government, retail trade, and professional and technical services (Table 4.4-10).

The annual unemployment rate in Klickitat County was 6.7 percent in 2007, and rose two percentage points to 8.2 percent in 2008. In comparison, the annual unemployment rate in Klickitat County in 2000 was 7.5 percent. Washington unemployment rates in 2007 and 2008 were 4.5 percent and 5.5 percent, respectively, and 5.0 percent in 2000 (Table 4.4-12) (WESD 2008). Per capita personal income in 2006 in Klickitat County was $27,827, which was 73 percent of the same measure for the State of Washington as a whole and similar to the income levels for Skamania County (BEA 2008). Median household income the same year (2006) was $44,843, or 80 percent of the same measure for Washington State as a whole ($56,184) (WOFM
Similar to in Skamania County, these rates reflect (1) a relatively depressed local economy, and (2) the current nationwide economic slowdown.

Note: This type of industry breakdown is not available for years beyond 2006.
NA = Not available

Of the three counties that surround the project site, Hood River County has the highest number of employed workers. In 2006, employment in Hood River County averaged 15,578 jobs, of which 12,179 (78 percent) were held by wage and salary workers and 3,399 (22 percent) by proprietors. Place of work earnings (wages, salaries and proprietors’ earnings) accounted for 59 percent of total personal income in the County, with income from property (dividends, interest and rent) and transfer payments (mainly Social Security) making up the balance. The principal sources of employment were manufacturing, health care and social assistance, local government, and retail trade (Table 4.4-11).

The annual unemployment rate in Hood River County was 4.6 percent in 2007, having fallen from 6.6 percent in 2000. The December 2008 unemployment rate in Hood River County was 5.7 percent. In comparison, the annual unemployment rate for Oregon as a whole was 5.1 percent in 2000 and 5.2 percent in 2007. The December, 2008 unemployment rate for Oregon
was 5.7 percent (Table 4.4-12) (OED 2009). Hood River County has the lowest unemployment of the three counties near the project site. The most recent available annual unemployment rate in Hood River County (2007) is roughly two percentage points lower than the same measures for Klickitat and Skamania counties and 0.6 percentage point lower than the same measure for Oregon as a whole.

a. The most recent annual statistics for Washington are for 2008 and are shown in this column. The most recent annual statistics for Oregon are for 2007. This column shows (for the Oregon areas) the most recent unemployment rate available for both Oregon and Hood River County, which is the December 2008 monthly unemployment rate.

Of the three counties that surround the project site, Hood River County has the highest per capita and median household income, although these measures remain below the state average. Per capita personal income in 2006 in Hood River County was $29,333, which was 88 percent of the same measure for the State of Oregon (BEA 2008). Median household income in 2007 was $47,159, or 97 percent of the same measure for Oregon State as a whole ($48,735) (USDA 2007).

These unemployment rates and income levels indicate that all three counties near the project have been affected by the national economic slowdown. The economic slowdown together with (1) the relatively high unemployment and low income levels in Skamania and Klickitat Counties, and (2) the decreasing federal payments for the Counties, translate to economic challenges for these three Counties in the near future.

Major employers in the region surrounding the Whistling Ridge Energy Project site include those listed in Table 4.4-13.

Skamania County is about 40 miles in length from west to east, and extends northward from the Columbia River into the Cascade Mountains and the Gifford Pinchot National Forest. The county covers 1,672 square miles and is part of an area recognized for scenic beauty and as a major water, highway, and railroad transportation corridor. Skamania County has historically been highly dependent on logging and the forest products industry. Recently, due in part to government restrictions on timber harvesting, economic activity has shifted away from logging and forest products to tourism and recreation.

</table>

Approximately 85 percent of land in Skamania County is currently owned by the federal government (Mill A Community Action Committee 2008), resulting in relatively low property tax revenues for the County and for local school districts. Federal programs have been in place for over 100 years to relieve the economic burden placed on the County and local schools by the relatively low property tax revenue. Most of these programs operated with or related to funds generated by the sale of timber on federal lands. Historically, approximately one-quarter of US Forest Service revenues, such as those from timber sales, have been returned to States and Counties in which national forest lands are located.
The Secure Rural Schools Act was enacted in 2000 to provide assistance to rural counties, such as Skamania County, affected by the decline in revenue from timber harvests in federal lands. Public Law 110-343, enacted on October 3, 2008, reauthorized and amended the Secure Rural Schools and Community Self-Determination Act of 2000 (Public Law 106-393). The new Secure Rural Schools Act authorizes distribution of funds only through 2011, and the distributions will decrease each year beginning in 2008 (USFS 2008). Consequently, Skamania County will need to find alternate funding for governmental services.

Economic uses on the project site include timber harvesting. The project site is on land managed for commercial forestry by S.D.S. Co., LLC and Broughton Lumber Company. The Applicant, Whistling Ridge Energy LLC, is wholly-owned by S.D.S. Co., LLC. All of the parcels on which the project would be constructed are managed for a continual cycle of growth, harvest, and replanting. As a longstanding commercial forestry site, no old-growth forests exist in areas where the project is proposed. Many of the stands of trees on the sections of land that would have turbines on them are near maturity. S.D.S. Co., LLC and Broughton Lumber Company have recently implemented timber harvest plans on portions of the land. Additional harvests are planned, subject to requirements of a Forest Practice Application.

Mill A and Willard consist entirely of housing. The lumber mill closed in 1988, and the school in Mill A has a declining population.

4.4.1.3 Fiscal Conditions

Washington State and Skamania County collect several types of taxes:

- Payroll taxes are paid in Washington by employers for compensation to unemployed or injured workers. Skamania County does not benefit from collection of payroll taxes.

- Washington’s Business and Occupation (B&O) tax is levied on the gross receipts of business operations. This revenue would not represent a benefit to Skamania County because all B&O tax revenues remain in the State budget. The amount paid in B&O tax could be less if the project qualifies for a credit under the Rural County B&O Tax Credit for New Employees program. Skamania County does not levy a business tax.

- Washington State collects retail sales and use tax. The sales and use tax rate for the unincorporated area of Skamania County is 7.0 percent, meaning that after the State government’s share of 6.5 percent, a remaining 0.5 percent goes to the County. Sales and use tax collected in Skamania County during calendar year 2007 was $630,515. Total taxable (sales and use) retail sales in 2007 was $39.8 million. Since 1995, taxable sales have decreased annually by as much as 34 percent (2001–2002) and increased annually by as much as 52 percent (2002–2003). Cumulatively, taxable sales increased over 50 percent between 1995 and 2007 (WDOR 2008).

- Skamania County collects property taxes for taxing districts within the County. Skamania County’s tax base, i.e., assessed value of real and personal property, was $1.134 billion in 2007 (WDOR 2009a). Skamania County collected (current and
delinquent) property tax of $9.6 million in calendar year 2007 (WDOR 2008). The average property tax rate for Skamania County in 2008 was $8.36/$1,000 assessed value (WDOR 2009b).

In 2008, the Skamania County Budget was $55,262,498, including $15.8 million for the Current Expense Fund and $39.5 million for all other County funds. The top four categories make up over half of the Current Expense Fund, and include General Services (21 percent), the Sheriff’s Department (16 percent), facilities and recreation (13 percent), and the jail (6 percent). Skamania County’s General Fund was categorized in 2007 as shown in Table 4.4-14.

4.4.1.4 Public Services and Utilities

Fire Protection

Two city fire departments (North Bonneville and Stevenson) and seven Skamania County fire districts provide fire protection to Skamania County residents. WDNR also provides fire suppression services to forested areas in Skamania County, and would be the first responder to a fire emergency at the project site (J. Weeks, personal communication). Skamania County Fire District No. 3 (SCFD3) provides fire protection and emergency response to a 20-square mile service area immediately south of the project site (Cox 2008). Although the project site is not formally within SCFD3’s service area (T. Skinner, personal communication), SCFD3 would likely respond to a fire at the project site, along with and in coordination with WDNR (R. Hovey, personal communication). The Mill A Fire Department is also near the project site, and has a staff that includes less than six volunteer firefighters and no paid personnel (Carlson, 2008).

The project site is located in WDNR’s West Klickitat Area. The WDNR work center closest to the project site is the Husum work center, which is staffed by one fire manager officer and one assistant fire manager (J. Weeks, personal communication). Other staff and equipment at the Husum work center includes six firefighters and two Type 6 wildfire engines (Fullerton and Helgerson 2008). The WDNR response time to the project site would vary depending on the location of the engines and the type of fire emergency at the project site, but would range from 45 minutes to one hour (R. Hovey and J. Weeks, personal communications). The engines are usually assigned to work projects in the field.

Skamania County Fire District No. 3 is located in the unincorporated community of Underwood and is staffed by 17 volunteer firefighters. The SCFD3 service area is 20 square miles. Equipment at District No. 3 includes one of each of the following: Type 1 engine, Type 2 engine, Type 3 engine, Type 7 engine, Type 2 tender, and Type 3 tender (Fullerton and
The Washington State Ratings Bureau rating for SCFD3 at the project site is “Unprotected – 10,” because the site is not located within the SCFD3 boundaries (T. Skinner, personal communication).

The project site is located outside of the Columbia River Gorge National Scenic Area. If an incident at or near the site, i.e., a wildland fire, threatens the area, the Columbia River Gorge National Scenic Area fire agency could respond. The fire agency is equipped with three Type 6 wildfire engines, one fire prevention module, two command vehicles, two cooperative engines (with the WDNR), and one cooperative engine (with the Oregon Department of Forestry). The Columbia River Gorge National Scenic Area fire agency has nine employees and is staffed seven days per week, July through September (Fullerton and Helgerson 2008).

Skamania County has prepared a Community Wildfire Protection Plan through a Title III grant from the Secure Rural Schools and Self Determination Act. This is a plan developed by a community in an area at risk from wildfire, with the goal of reducing the risk of catastrophic wildfire within the region. Topics addressed in a typical Community Wildfire Protection Plan include wildfire response, hazard mitigation, structure and water source protection, education, and community preparedness (Fullerton and Helgerson 2008).

Table 4.4-16 lists the fire departments that serve the site and surrounding area, along with the departments’ staff and equipment. These fire districts have mutual aid agreements with each other (J. Carlson, personal communication).

**Law Enforcement**

The Skamania County Sheriff’s Office would provide law enforcement services to the project site. Sheriff’s Office headquarters are located at 200 Vancouver Avenue in Stevenson, approximately 15 miles southwest of the project site. The Sheriff’s Office also operates a substation in Cougar that serves the northern portion of Skamania County. Cougar is located more than 50 miles northwest of the project site (Cox 2008). The Sheriff’s Office staff includes 23 commissioned officers, two reserve officers, four civil staff, and 14 jail staff. At any one time, at least two officers patrol the County. Response times to the project site depend on the location of patrol vehicles when the call for service is received. The response time from Sheriff’s Office headquarters to the project site is approximately 20 minutes (Cox 2008).

Other law enforcement agencies providing service near the project site include the Washington State Patrol, which patrols SR 14 south of the site. Construction and equipment delivery vehicles would travel on SR 14. Roads extending north of SR 14 are county roads, and are patrolled by the Sheriff’s Office (Cox 2008). All 39 Washington State county sheriffs sign a mutual aid agreement annually.

Sources: Fullerton and Helgerson (2008), Washington State Patrol (personal communication), MSRC (2008), J. Carlson (personal communication).

a. T. Skinner (personal communication): As rated by the Washington Surveying and Rating Bureau. The Bureau rates the level of fire protection provided by fire departments against four main elements: available water supply; logistical characteristics and makeup of the district fire department; available communications systems; and finally fire control and safety measures taken and ordinances in effect in the particular fire district. Ratings are used to evaluate fire protection availability for insurance purposes. Ratings range from 1 to 10, with class 1 representing the highest level of fire protection and class 10 the lowest level. Ratings were not available for the Washington Department of Natural Resources or the Columbia River Gorge National Scenic Area Fire Agency.

b. Not available.

The Vancouver District (No. 5) of the Washington State Patrol would provide law enforcement services to SR 14 near the proposed Whistling Ridge Energy Project site, but would not respond to calls for service at the project site. The Washington State Patrol Vancouver District has approximately 60 commissioned officers, and serves the population living in Cowlitz, Lewis, Clark, Klickitat, and Skamania counties. In addition to the Vancouver District, four detachment offices are located in Chehalis, Morton, Kelso, and Goldendale. The detachment office closest to the project site is the Goldendale Detachment, which covers Klickitat and Skamania counties, and more than 230 miles of state routes. In addition to SR 14, the Goldendale Detachment is also responsible for SR 97, SR 141, SR 142, and SR 197 (Washington State Patrol, personal communication).

The Goldendale detachment has nine commissioned officers (Washington State Patrol, personal communication). Table 4.4-17 shows that the staffing level per capita for the Skamania County Sheriff’s Office is higher than the average for Washington State.

Emergency Medical Services

Two ambulance companies would respond to an emergency at the Whistling Ridge Energy Project site: Skamania County Emergency Medical Service and Skyline Ambulance. Skamania County Emergency Medical Services is the functioning entity of Skamania County Hospital District No. 1, which provides ambulance service to the residents of Skamania County. Skamania County Emergency Medical Services is located in Stevenson and is equipped with three medic vehicles, one rescue vehicle, and two squad vehicles. Skyline Ambulance is based at Skyline Hospital in White Salmon, and is equipped with three ambulance vehicles (Skyline Hospital 2008). Table 4.4-18 lists characteristics of the first response ambulance service providers for the Whistling Ridge Energy Project site.

Sources: Cox (2008), Skyline Hospital (2008), Skamania County EMS (2008).

The two hospitals closest to the project are Skyline Hospital in White Salmon (7 miles southeast of the project) and Providence Hood River Memorial Hospital in the City of Hood River (8 miles southeast of the project). Skyline Hospital is a 32-bed acute care hospital with a Trauma Level IV designation, serving western Klickitat County and eastern Skamania County. Services at Skyline Hospital include acute care, obstetrics, surgery, cardio-pulmonary care, radiology and laboratory services, physical therapy, a pharmacy, and emergency services. Skyline Hospital owns and operates a three-vehicle ambulance service (Skyline Hospital 2008).

Providence Hood River Memorial Hospital is a 25-bed facility that provides Cardio conditioning, counseling, diabetes treatment, a dialysis center, emergency services, obstetrics, radiology, laboratory services, nutrition, occupational medicine, a sleep center, and surgery.

Schools

In October, 2007, the total student enrollment in Skamania County public schools was 1,213 students, representing approximately one-tenth of one percent of total enrollment in Washington that year (Washington State OSPI 2008). Five school districts provide public education services.
to Skamania County residents. The service areas for four of the five districts are completely within Skamania County boundaries. These four districts are Mill A School District No. 31, Stevenson-Carson School District No. 303, Skamania School District No. 2, and Mount Pleasant School District No. 029-93. The fifth district, Washougal School District No. 112-6, is under Clark County jurisdiction, but has a service area that extends into the western portion of Skamania County. Table 4.4-19 shows that over the last few years, enrollment in these five districts has not changed more than five percentage points, on average (Washington State OSPI, 2008).

Mill A School District No. 31 provides public educational services to the population in the southeastern corner of Skamania County, a service area adjacent to the project site (ESD 2008). Mill A School currently enrolls 81 students in grades K through 8. High school students living within the boundaries of the Mill A School District attend Stevenson High School in the Stevenson-Carson School District No. 303, which borders Mill A School District No. 31 on the west. Mill A School and district offices are located at 1142 Jessup Road in the community of Cook, which is located approximately 5 miles south of the project site (Mill A School District 2008).

The public school closest to the project site is the Mill A School, which is approximately 2 miles southwest of the site. The next closest public schools are in the community of Carson, approximately 10 miles west of the site. School buses may drive through neighborhoods near the project site, including the communities of Willard and Mill A, which are located approximately 2.25 and 1.5 miles respectively from the site.

The higher education facilities closest to the site include Clark College, a community college in Vancouver, and Washington State University’s Vancouver campus (SCCC 2008).

**Parks and Recreational Facilities**

Parks and other recreational facilities are discussed in Section 4.2.4, Recreation.

**Utilities**

Embarq provides telephone service to the area surrounding the site (Cox 2008). The Skamania County Public Utility District (PUD) is a customer-owned utility that provides electricity service.
to Skamania County. The homes and businesses in Mill A and Willard do not have sewer service or water service. They are on wells and have septic systems. Skamania County provides solid waste pick-up service to residences and businesses in the County, including those near the project site (Skamania County PUD office staff, personal communication).

Discussions of water supply systems and stormwater control systems at the Whistling Ridge Energy Project site and in the site vicinity, as well as project-related impacts on these facilities, can be found Section 2.5 Water Supply System, Section 2.10 Surface Water Runoff, and Section 3.3 Water.

4.4.2. IMPACTS

This section describes the expected impacts of the project on local socioeconomic resources. The project would generate new local employment, additional business for local service and materials providers, and additional tax revenues to Skamania County and the state. The overall permanent socioeconomic impact of the project would be positive. Impacts were estimated through a detailed review of the proposed action against existing conditions.

4.4.2.1 Construction

Business and Economic Impacts

Section 2.12, Construction and Operation Activities provides information on the construction costs and schedule and projected manpower loading for the project. Assuming the Governor approves the Site Certification agreement in April 2010, the Applicant anticipates beginning design and construction in 2010 and operation by 2011. During the estimated one-year construction period (excluding engineering, design, specifications, and survey), approximately 330 full-time and part-time workers would be employed at some point during construction. Some of these jobs would not last the entire construction period. The on-site construction work force would peak at approximately 265 workers over the construction period and average 143 workers over the 12 months.

Table 4.4-20 presents the expected average composition of the construction work force. Construction trades would be broken down as shown in Table 4.4-21.

An estimated 65 to 75 percent of the construction labor force would likely be hired from the Portland-Vancouver metropolitan area. An estimated 25 to 30 percent of the workers would be residents of the three-county area including Skamania, Klickitat, and Hood River counties (A. Barkley, personal communication). This estimate is based on the relative size of the labor force in the three-county area compared to larger labor forces in metropolitan areas that are further away. Most construction workers hired from the Portland-Vancouver metropolitan area (65 to 75 percent) are expected to commute on a daily basis due to the 61-mile distance to the site.

</table>

To ensure that the applicant uses the local labor pool to the greatest extent possible, construction contractors would be required to advertise positions locally and to employ local workers to the greatest extent possible. Top hiring priority for construction would be given to qualified in-county and in-state construction workers. Some of the more specialized skills required for certain plant construction activities may not be available in the local or state labor pools; therefore, a small percentage of the work force may have to be brought in from outside of both Washington and Oregon states. These workers (up to 15 percent of the workforce [A. Barkley, personal communication]) would likely be employed for a short period of time, and would reside in motels in the project area for the duration of their assignments.

The average of up to 21 specialized out-of-state workers (40 at peak), and an estimated average 31 (57 peak) weekly-commuting construction workers\(^2\) (would generate additional business for

\(^2\) These weekly-commuting construction workers represent one-third of the workers originating from the Portland-Vancouver metropolitan area, as a worst-case scenario.
the operators of transient accommodations, such as motels, recreational vehicle parks, and campgrounds, as well as for other businesses near the project area. Also, a portion of the construction materials and services needed for the project would be procured from local vendors, thus generating additional income for local suppliers.

Whistling Ridge Energy Project non-salary local procurements\(^3\) for construction materials, services and equipment leasing associated with construction are projected to total approximately $13.2 million. These procurements would augment the revenues of many construction-related businesses in Skamania County and the three-county area in general. In addition, the consumption spending of local project workers and their households out of their wages and salaries would stimulate the retail trade and services sector of the local and regional economies. Total payroll costs for project construction, including fringe benefits and other labor overhead costs, are projected to be approximately $18 million, of which approximately $4.5 million is expected to be earned in the three-county area including Skamania, Klickitat, and Hood River Counties.

An analysis of the primary and secondary effects of these construction spending streams within the three-county area reveals that indirect and induced value added from construction would be $3.9 million, and that 71 indirect and induced jobs would be attributable to construction. The total economic impact (direct, indirect, and induced) is expected to be $8.5 million in value added and 107 jobs (IMPLAN 2008). Project construction would create a total of 107 jobs in the three-county area, which would continue throughout the construction period.

Table 4.4-22 shows the direct, indirect, and induced economic effects of construction of the project in terms of its contribution to gross regional product (value added) and creation of employment (number of jobs) in the local area, including Skamania, Klickitat, and Hood River counties. Table 4.4-22 shows the breakdown of these effects by industry.

The estimates in Table 4.4-22 were calculated using an IMPLAN economic input-output model specific for the three-county area and the Whistling Ridge Energy Project. Local expenditures related to project construction would affect the three-county area economy directly through the purchases of goods and services in the region, and indirectly as those purchases, in turn, generate other purchases of intermediate goods and services from related sectors of the economy. In addition, the direct and indirect increases in employment and income enhance the overall purchasing power of residents, thereby inducing further consumption and investment. Number of jobs is the full-time equivalent of person-years of construction employment.

\(^3\)Local procurements are procurements that would occur with the three-county area including Skamania, Klickitat, and Hood River Counties.

<sup>a</sup> In millions of 2008 dollars
Totals may not add due to rounding.
North American Industry Classification System categories that are 0 are not shown.
Construction activities such as earth movement and vehicle traffic would generate noise and dust, which would represent a temporary nuisance to nearby businesses. In addition, traffic delays could occur on the existing roadway network due to the maneuvering of large vehicles carrying heavy or long loads. Nuisances and traffic delays related to construction would be temporary and are not expected to affect employers’ ability to conduct business.

**Population and Housing Impacts**

The approximately 15 percent of the construction work force that would be specialized craftsmen originating outside of Washington and Oregon would likely have relatively short assignments, so few are expected to bring their families with them when they arrive to work on the project. The population increase in the project area and elsewhere in the three-county area would therefore be limited mainly to these workers for a temporary period of time, plus, during the work week, the non-local workers who would temporarily commute on a weekly basis from the Portland-Vancouver area.

The total estimated number of workers requiring transient housing would be 52 (average) and 97 (peak) over the 12-month construction period, assuming that one-third of the workers from the Portland-Vancouver metropolitan area would commute on a weekly basis and the specialized, temporary staff also would require lodging. These construction workers are expected to seek temporary accommodation in the general vicinity of the project site, and to use motels, trailers, campers, and other forms of transient housing. Table 4.4-8 shows that approximately 1,082 hotel rooms or RV campsites exist within 25 miles of the project site. Assuming 70 percent occupancy, approximately 325 of these units (313 hotel rooms) would be available at any one time. Assuming a worst-case scenario that workers would want hotel or motel lodging, the peak demand of 97 rooms (assuming, again a worst-case scenario that no workers would share rooms) would represent approximately 31 percent of the available rooms and would therefore not stress the lodging facilities within 25 miles. Construction of the proposed project is not expected to result in a significant impact on transient accommodation availability in the project vicinity, nor is the project expected to affect median housing values, median gross rents, or new housing construction. The applicant has no plans to provide on-site temporary housing for workers or shuttle to or from hotels or other temporary lodging facilities.

Access to the proposed project site would be via Skamania County roads that extend northward from SR 14 and an existing private logging road. From SR 14, vehicles would travel along Cook-Underwood Road, Kollack-Knapp Road, Scoggins Road, and a private logging road listed as CG2930. The private logging road is located on the Applicant’s (S.D.S. Co., LLC and Broughton Lumber Company) property, and would provide access to most areas where project facilities would be located.

**Fiscal Impacts**

**Sales Tax Revenue**

The total cost of construction is estimated to be approximately $150 million. In addition to the local area procurements mentioned above, the Applicant would be purchasing large amounts of
wind power generation equipment from various domestic and foreign suppliers. Depending on legislation currently under consideration in the state legislature, state sales and use tax may be levied only on procurements that are not directly related to electricity generation. Should the state sales tax exemption for wind power be extended, capital equipment such as turbines, transformers, transmission cables, and substation equipment would not be taxable.

The local procurements are estimated to be 10 percent of total procurements (approximately $13.2 million). The majority (estimated at 90 percent) of local procurements would be directly related to electricity generation. Taxable sales due to project construction would therefore be approximately $1.32 million, resulting in $92,400 in sales and use tax revenue for Washington State and Skamania County taxing districts.

The Skamania County sales and use tax rate for the unincorporated area is 7.0 percent, meaning that after the state government’s share of 6.5 percent, a remaining 0.5 percent goes to the County. Due to the project’s location within the unincorporated area of Skamania County, Skamania County would receive $6,600 of the $92,400 in sales and use tax revenues related to project construction. This one-time influx of revenue ($6,600) would represent an increase of one percent when compared to the sales and use tax collected in Skamania County during calendar year 2007 ($630,515) (WDOR 2008). These positive fiscal impacts to the County and the state would be a one-time occurrence resulting from project construction activities.

Modest increases in sales of goods and services would occur during construction, such as local purchases by construction workers. Sales tax revenues resulting from these types of purchases would be beneficial although small within the context of the Skamania County economy.

**Property Values and Property Tax Revenue**

The project site is located on undeveloped land in a forest land zone. The nearest residences are approximately 0.5 mile northwest of the site, and approximately 0.4 mile (2,000 – 2,500 feet) southeast of the site. Construction traffic would go through Underwood, which would experience additional truck traffic for a period of up to nine months. Construction activities are not likely to adversely affect property values in residential and commercial areas near the project site because the construction period would be relatively short. Construction of the project would not affect property tax revenues.

**County Expenditures**

Skamania County could experience a small increase in traffic-related costs due to the need for permitting and control measures related to over-size or over-weight loads carrying equipment such as tower sections, nacelle, turbines, and blades. Construction of the project would require that many construction vehicles, including trucks with over-size and over-weight loads, share the existing roadway network with the general public. As a result, some accidents could occur that would be directly attributable to construction traffic. An increase in accident occurrence during the construction of the project could take place, but any increase is expected to be minimal.

The County could experience a small increase in cost of public services such as fire suppression, law enforcement, governmental services, parks and recreation, and hospital costs during
construction due to the additional traffic and the temporary population. These potential additional costs would be temporary and negligible within the context of the total costs for services in Skamania County.

The benefits of the project, including additional jobs, income, spending, and tax revenue, would outweigh the small amount of costs Skamania County could potentially incur. Both the benefits and costs associated with construction would be temporary and would occur concurrent with the one-year construction period.

**Public Services and Utilities**

The influx of construction workers into project area communities on a daily and weekly basis could result in a minor and temporary increase in the demand placed on public service providers. This increase in demand could have a minor and temporary effect on local police departments, providers of emergency medical services, and local fire departments. The contractor would develop emergency plans for project construction.

The impact of project construction on local schools would be at most minor and temporary, as few out-of-state construction workers are likely to be accompanied by families. Construction-related impacts to local utilities are also expected to be minor and temporary.

Response times in the project vicinity are not expected to change due to project construction. Construction trucks would represent additional volume on area roads, but would not deter any emergency vehicles from travel. The project would be constructed entirely within land managed for commercial forestry by the Applicant.

Anticipated water uses during construction include spraying roads for dust control, construction support (such as concrete curing and hydrostatic testing of equipment), and restroom facilities for the estimated average of 143 and peak of 265 construction and support workers. Water needed for construction would be purchased by the contractor from an off-site vendor with a valid water right and transported to the project site in water-tanker trucks.

The project would require the improvement of approximately 7.2 miles of existing private logging roads. In areas near proposed wind turbine strings where no logging roads currently exist, approximately 2.4 miles of new gravel access roads would be constructed. Some of these construction roads would continue to be used during the project’s operational phase.

The needs of public service providers are considered in Section 4.3, Transportation. Section 4.2.4, Recreation addresses the potential for impacts on parks and other recreational facilities.

**4.4.2.2 Operation**

**Business and Economic Impacts**

Operation of the project would result in a positive economic impact to Skamania County, the three-county area, and the State of Washington due to increased tax revenues, employment, and local expenditures. Operation of the project would likely require eight to nine full-time or part-
time Operations and Maintenance employees. Efforts would be made to hire local individuals to staff the project as much as practicable.

The estimated gross payroll (including fringe benefits and other payroll overheads) for the operational workforce is $1.5 million, or an average annual labor cost of $167,000 to $188,000 per employee. This is approximately 25 percent higher than the standard industrial wage for this industry in Skamania County (IMPLAN 2008). In addition to the regular operational workforce, a temporary workforce with appropriate skills would be utilized during major maintenance or other non-routine operational work.

Using IMPLAN regional economic modeling software for the power generation and supply industry in the three-county area including Skamania, Klickitat, and Hood River Counties, a wind power facility employing nine full-time workers would have a gross annual operating cost valued at approximately $3.75 million, which would include direct purchases from suppliers (including fuels, maintenance supplies and services, retail goods and professional services). Sales, use and other indirect business taxes on that level of spending are estimated at $200,000 (IMPLAN 2008) per year, which would accrue to state and local government jurisdictions. Employee spending from wages and salaries is estimated at around $900,000 per year, assuming an average local expenditure rate of 70 percent of compensation.

Table 4.4-23 shows the direct, indirect, and induced economic effects of operation of the project in terms of its contribution to gross regional product (value added) and creation of employment (number of jobs). The estimates in the table were calculated using an IMPLAN economic input-output model for the three-county area including Skamania County, Klickitat County, and Hood River County.

a. in millions of 2008 dollars
b. totals may not add due to rounding
North American Industry Classification System categories that are 0 are not shown.
Operation of the project would result in a total of 12 permanent jobs, including direct, indirect, and induced effects. For comparison, the Renewable Energy Policy Project estimates that every megawatt of installed wind capacity creates about 4.8 job-years of employment, both direct (manufacturing, construction, operations) and indirect (advertising, office support, etc.) (REPP 2009). Using this standard, the Whistling Ridge Energy Project, which would produce approximately 75 MW of electricity, would result in 600 job-years (60 jobs each year over 10 years, for example). In comparison, this analysis finds that the project would result in 78 jobs for the construction period, and 12 jobs each year for the estimated 30 year life of the project.

Expenditures related to project operation would affect the three-county area economy directly through the purchases of goods and services in the region, and indirectly as those purchases, in turn, generate other purchases of intermediate goods and services from related sectors of the economy. In addition, the direct and indirect increases in employment and income enhance the overall purchasing power of residents, thereby inducing further consumption and investment. Number of jobs is the full-time equivalent of person-years of employment.

Project operations would not affect local businesses’ ability to conduct operations.

**Lease Payments and Royalties**

Whistling Ridge Energy LLC would lease land for the project from S.D.S. Co., LLC and Broughton Lumber Company.

**Population and Housing Effects**

Operation would require up to nine permanent employees. For the IMPLAN model, an estimated seven employees were assumed to originate from the three-county area. The remaining two employees could migrate to the area from other locations outside the three-county area. Assuming an average household size of 2.6 persons, the population in the area could increase by approximately five people, and two households. Assuming the most recent average housing vacancy rate available (2008) for Skamania County (16.8 percent), more than 900 housing units would be available in Skamania County alone, not including the additional nearby housing in Klickitat and Hood River counties. Even if both of these new project-related households choose to locate in Skamania County, the population increase would not represent an adverse impact on population or housing demand in the area.

The project would not displace any minority or low-income populations. The project would be constructed on private land not occupied by residents or businesses owned by anyone other than the Applicant. As discussed in Section 4.4.1.1, the area near the project does not have a substantially higher minority or low-income population when compared to larger reference populations. Section 4.1, Environmental Health, states that infrasound (noise) potential impacts are considered to be either non-existent or less than significant during operation. Permanent visual changes due to project operation would be low to moderate. Therefore, this analysis finds that high and disproportionate impacts upon minority and low-income populations would not occur.
Fiscal Impacts

Property Values

Local communities near proposed wind turbine locations have expressed concern that constructing wind turbines would detract from views, which would in turn decrease their property values. In order to address this concern and potential socioeconomic impact of the Whistling Ridge Energy Project, two studies were found that (1) review literature related to property values and wind projects, and (2) analyze property value impacts of wind projects.

The first study is entitled “Economic Impacts of the Kittitas Valley Wind Project” (the Kittitas Study) (ECONorthwest 2006). The Kittitas Study was prepared in 2006 by ECONorthwest for the Economic Development Group of Kittitas County, Washington. The Kittitas Study is an update to the “Economic Impacts of Wind Power in Kittitas County” study (ECONorthwest 2002). The Kittitas Study finds that “views of wind turbines will not negatively impact property values…based on a nationwide survey conducted of tax assessors in other areas with wind power projects, [the authors] found no evidence supporting the claim that wind farms decrease property values” (ECONorthwest 2006). The authors also conducted a literature review, and testified that “information from tax assessors and related literature indicate that views of wind turbines do not negatively affect property values” (EFSEC 2006).

The second study, is entitled “The Effect of Wind Development on Local Properties,” and was prepared by the Renewable Energy Policy Project, a government agency in Washington, D.C. (REPP 2003). The REPP Study states that because installed wind power capacity in the US grew 26 percent annually (on average) between 1998 and 2002, any impacts on property values would likely have been evident in 2003, when this study was conducted. The REPP Study reviewed data on property sales near wind projects and used statistical analysis to estimate whether and to what extent wind projects affected prices at which properties were sold.

The authors of the REPP Study chose 10 projects that were (1) 10 ms or greater installed wind capacity, and (2) built during the period 1998 to 2001. They chose five-mile radius study areas around each wind project because they found that wind turbines are not highly noticeable beyond five miles. The authors collected property sales data over a period of six years, straddling the on-line date of the projects. The goal was to collect data for three years preceding and three years following the on-line date of the project. The authors gathered data for the view shed, and for a community comparable to the view shed, but without the presence of the wind turbines. The database for the study held over 25,000 records of property sales in the view shed communities and the comparable communities. The REPP Study found that:

- In eight of ten cases, property values increased faster in the view shed than in the comparable community
- In a study of the view shed only (not the comparable community), in nine of ten cases, property values increased faster after the project came on line than before
- In nine of ten cases, property values increased faster in the view shed than they did for the comparable community during the period after the projects came on line
The results of the REPP Study statistical analysis provides no evidence that wind development has harmed property values within the view shed (REPP 2003).

The Whistling Ridge Energy Project would be located in an undeveloped area, away from large population or industry centers and primarily zoned as Unmapped by Skamania County (wind energy facilities are an outright permitted use in the Unmapped area). Approximately 400 homes or businesses exist within three miles of the project site—approximately one-third of these 400 are located in Willard. The closest home would be located to the southeast of the Project Site, approximately 2,000 – 2,500 feet away. Homes and businesses near the project, as well as those further away, such as across the Columbia River, could have views of the turbines. Section 4.2.3 discusses the potential impacts to views attributable to the project. Based on the findings of the two studies discussed above, the project would not likely result in decreasing property values for properties with views of the wind turbines. The Applicant is not aware of any other studies or information (of a non-anecdotal nature) that would indicate a likelihood of negative impacts on property values for a setting such as that near the project.

**Sales Tax Revenues**

The permanent operation employees and the local procurement of supplies and equipment for operations and maintenance would generate modest additional economic activity due to their local spending. This activity would result in a small and beneficial increase in sales tax revenue for Skamania County.

**Property Tax Revenue**

An increase in the tax base equal to the numbers of turbines multiplied by an estimated value of $1.75 million per turbine ($87.5 million) would represent an increase of 6.5 percent in assessed value in the County. Using the average property tax rate for Skamania County of $8.36/$1,000 assessed value (WDOR 2009b), the increase in property tax revenue to the County would be $731,500 and would represent a permanent, annual increase of 7.6 percent compared to the amount of property tax collected (current and delinquent) in calendar year 2007 ($9.6 million) (WDOR 2008). Property tax revenues would be higher to the extent that increased wages and economic activity in the County results in higher valued properties.

Using a standard for wind projects given by the National Wind Coordinating Committee of $10 to $14 in property taxes for each $1,000 investment (NWCC 2009), the $17.7 million dollars spent locally (labor and non-labor cost) due to this project would result in approximately $177,000 to $250,000 in property taxes, which is lower than the estimate above. To the extent the wind turbines depreciate over time, the assessed value of the turbines and therefore the property tax revenue would decrease.

These additional and permanent annual revenues could help satisfy the need for alternate funds to replace decreasing federal funding. Assuming that the annual tax revenue of $731,500 would be distributed among funds as shown in Table 4.4-15, funds receiving the most revenue would be the State School Fund ($185,281), School District 405 Maintenance and Operations ($149,461), the County Road fund ($115,035), and the Current Expense fund ($111,086). A portion of the
State School Fund would be returned to Skamania County for Skamania County schools (L. Moore, personal communication).

**County Expenditures**

Skamania County could experience a negligible increase in demand for and cost of public services (fire service, law enforcement, governmental services, parks and recreation, and hospital services) due to project operation. Changes due to the project would include additional roads and five residents living in the three-county area. An estimated two workers and their families would permanently relocate to the area. These additional costs would be negligible within the context of the Skamania County budget and the permanent economic and fiscal benefits attributable to project operation.

The benefits of the project, including permanent jobs, income, spending, and tax revenue, would outweigh the costs Skamania County could potentially incur, even as depreciation of project equipment causes a decrease in property tax revenues in the project’s later years. The increase in property tax revenue would begin one year after construction is complete, and continue for the life of the project.

**Public Services and Utilities**

No new BPA infrastructure would be needed for the electrical transmission interconnection system. The project substation would occupy a portion of a fenced 5- to 6-acre area in the southwest part of the project site, immediately adjacent to the BPA 230-kV transmission line. The collector system would collect energy generated at 575 volts (depending on model) from each wind turbine, and transform the voltage to 34.5 kV using a pad-mounted transformer. Then, the collector would deliver the energy via underground cables to the project substation, which would further transform the energy from 34.5 kV to 230 kV and deliver it to the adjacent BPA transmission line and into the regional transmission system. The project would require approximately 8.5 miles of underground collector cable trenches.

A permanent Operations and Maintenance facility would be constructed on a 2-acre area adjacent to the substation. The Operations and Maintenance facility would have approximately 3,000 square feet of enclosed space, including office and workshop areas, a kitchen, bathroom, shower, and utility sink.

Upon completion, the project would be connected to the following established utility systems:

- Electric service: Skamania County PUD/BPA connection
- Sewer Services: on-site
- Drinking Water: on-site
- Telephone: Embarq and Sprint
- Non-hazardous waste pick-up: Allied Waste
The Applicant would develop fire, emergency, and illness plans for project operation (see Section 2.16, Security Concerns). Water and sewer facilities for the project would be developed on site by the Applicant. Water for the bathroom and kitchen would come from a new on-site well. Project operations would require less than 5,000 gallons of water per day. The bathroom and kitchen would drain into an on-site septic system. A graveled parking area for employees, visitors, and equipment would be located adjacent to the Operations and Maintenance facility. The entire project site (including Operations and Maintenance facility, parking area, utilities, and turbines) would be fenced and have a locked gate.

Considering the small number of on-site employees (eight to nine) and the use of on-site services and emergency response plans and devices, the project is not expected to place an unacceptable additional demand on local public services.

The Sheriff’s Office resources are generally adequate to serve the project during construction and operation, given that onsite security is provided by a separate party (Cox 2008). The Applicant would likely contract locally for private security.

WDNR resources for fire protection and suppression services are adequate to serve the project during construction and operation (J. Weeks, personal communication).

The project would not result in a decrease in response times for area service providers during operation. The project’s eight to nine permanent employees would not represent a substantial increase in traffic volumes on area roads, nor would project facilities result in additional traffic controls.

The addition of potentially two new households could mean increased demand at Mill A School District or other nearby school districts. Assuming every two households represent the addition of one school-age child, enrollment at any of these districts could increase by 1.5 percent at most, representing a less-than-significant impact.

There would be a potential positive impact on public services and utilities due to project operation. The project’s assessed value could be $87.5 million, and would generate approximately $800,000 per year in generation, property and sales tax distribution to municipal, county and other local jurisdictions. A portion of these funds could be used to upgrade existing public services and utilities in the County.

**4.4.3. MITIGATION**

Socioeconomic impacts are expected to be beneficial in the form of additional jobs, increased sales, and increased tax revenues. Temporary increases in population due to worker relocation during construction are likely to be less than significant in view of the availability of housing, transient accommodations, and other public services in the region. Specific mitigation measures to lessen the impacts of the construction phase on public service providers in the Whistling Ridge Energy Project vicinity include:
• Construction activities would be coordinated with local police and fire departments, as well as emergency medical service providers, to ensure access to all locations in the project site vicinity in the case of an emergency.

• To help mitigate loss of access and other traffic-related impacts, adequate traffic control and signage, indicating closures and alternate routes, would be provided where needed.

• Construction vehicle trips in and out of the immediate construction zone would be coordinated and scheduled away from peak travel periods as much as possible, to minimize general traffic disruption.

• Noise and dust problems generated by construction would be mitigated through the use of properly muffled construction equipment, and by the use of approved dust control methods.

For related discussions of impacts and mitigation, see Section 3.2 Air, Section 4.1 Environmental Health, and Section 4.3 Transportation.
SECTION 5.1 AIR EMISSIONS PERMITS AND AUTHORIZATIONS  
(WAC 463-60-536)

Pursuant to WAC 463-60-115, Whistling Ridge Energy LLC requests a waiver of the information required by WAC 463-60-536, which calls for a PSD permit application and a Notice of Construction Application.

The fuel source for the Whistling Ridge Energy Project is wind transformed from kinetic energy into electrical energy by wind turbine generators. The project would not be subject to PSD regulations since it would not emit more than 100 tons per year of a regulated pollutant. As no air emissions would be generated from operation of the wind turbine generators, a PSD Permit and Notice of Construction Application would not be required.
SECTION 5.2 WASTEWATER/STORMWATER DISCHARGE PERMIT APPLICATION  
(WAC 463-60-537)

5.2.1 WASTEWATER DISCHARGE

EFSEC has jurisdiction regarding the NPDES Permit over the project pursuant to WAC Chapter 463-38. Construction of the facility would disturb more than five acres of land, and EFSEC may determine that the Whistling Ridge Energy Project obtain coverage under Ecology’s Stormwater General Permit for construction activities.

If coverage is deemed necessary by EFSEC, at least 30 days prior to beginning construction, Whistling Ridge Energy LLC would develop and submit to EFSEC a notice of intent to be covered by Ecology’s 2005 Construction Stormwater General Permit for discharges associated with construction. Pursuant to the general permit, Whistling Ridge Energy LLC would prepare SWPPPs that identify appropriate BMPs to reduce the pollution loadings resulting from construction activities and industrial operations. These BMPs would be incorporated into project design, and Whistling Ridge Energy LLC would ensure that they are observed during construction of the project. Monitoring and reporting would be carried out in accordance with permit requirements.

1 INTRODUCTION

1.1 GENERAL

The purpose of this report is to provide preliminary geotechnical feasibility and recommendations regarding design of wind turbine tower-foundations and approach roads for the Saddleback Wind Energy Project (SWEP). This is at site located approximately 7 miles west of the town of White Salmon, Washington, and approximately 2 miles east of the Little White Salmon River. The location of the site is shown on Figure 1, Vicinity Map.

The project area is located on private land immediately north of the Columbia River Gorge National Scenic Area boundary. The area of the proposed project is approximately 3.2 square miles (2000 acres). The Project site is located on a series of north trending ridges that range in elevation from approximately 2100 to 2300 feet above mean sea level (msl). The land west of the proposed Project site drops sharply to a narrow river terrace and then to an elevation of less than 800 feet above msl in the Little White Salmon River valley. The topography to the northeast of the site drops gradually toward the White Salmon River or climbs gently up the northeast flank of Underwood Mountain (2,728 ft above msl). To the south, the topography drops to the Columbia River.

1.2 PROPOSED CONSTRUCTION

The SWEP project involves the installation of approximately forty-eight wind energy turbines at its White Salmon, Washington site. As of the date of this report, the tower designer and tower locations have not been finalized. Because of this, the exact bearing capacity of the foundations required to support the Wind Turbine Generators (WTG) is not known. URS received information from a proposed turbine construction contractor, D.H. Blattner & Sons, Inc. which preliminarily assumed installation of 80-meter high GE 1.5 WTG which will be supported by 30 foot-deep concrete foundations. Each turbine tower will be coupled to the foundation with 128 rock anchor (consistent with GE towers). Final foundation design will be developed after detailed investigation and when designs are finalized.

Construction and Maintenance access to the proposed tower locations will be achieved by improving existing roadways that have historically been used primarily in support of logging activity and for access to existing BPA transmission lines. Modification of the roadways will be necessary to support the long and heavy loads that will be required for delivery of the wind turbine systems.
1.3 SCOPE OF WORK

To complete this preliminary report, URS has completed the following scope of work.

**County Roads - Pavement Engineering** – Upon speaking with the County personnel URS recommends that best pavement approach at this time would be to develop a “pavement assessment and design” strategy rather than a comprehensive field effort – as the field conditions will likely change over the next couple of years. The plan entails the following and is located in Appendix C:

- Anticipated routes for the project
- Existing pavement sections along the route – as they are best known (field verification of the actual sections later)
- Estimate axle weights and number of trips for trucks
- Strategy and design parameters for the haul roads on SDS property
- Strategy for pavement assessment just prior to heavy hauls, and strategy for pavement assessment upon completion of the heavy hauls

**Landslide Hazards** – URS completed a landslide assessment which should be repeated just prior to site development so that we would be able to note changed conditions. This work is presented in a Appendix D of this report and entails the following:

- Review of existing published geologic and geologic hazards literature for the site.
- Review of Sections of the County Code that address Geologically Hazardous Areas;
- Review of aerial photographs if they are available. URS will also review public groundwater records for the immediate area, as available.
- Conduct a site visit to evaluate site conditions. This will include evaluating the geologic conditions and existing slopes as well as geologic activities (slides, faulting, rupture, etc.) that may have influenced geologic hazards at the site. URS anticipates this will take approximately one day of field work.

**Preliminary Geotechnical Engineering** – URS has developed a preliminary foundation design based on the encountered foundation conditions. To complete this, URS did the following:

- Reviewed of the URS / Dames & Moore project files for information pertaining to this project. URS will review geologic maps of the area to further understand the soils prior to investigation.
- URS personnel met with the Owner's site representative just prior to investigation. The tower designer has not been identified for the project site, and the exact locations of the towers have not been identified. Therefore, URS will not perform any deep subsurface explorations at the site. We will, however, perform up to twelve 15-foot deep test pits that will be excavated by a SDS Employee. The test pits will be backfilled with the excavated soils.
• Along the roadway areas, URS assessed the near surface capacity and modulus of the onsite soils by performing a total of 30 dynamic cone penetrometer tests (DCP) located selectively across the existing roads. Each DCP probe was advanced to approximately 3 feet, or refusal, whichever is greater, below existing grade or the pavement surface to accurately determine the insitu subgrade characteristics. The DCP will furthermore clearly delineate between layers of weak and strong subgrade soils. The DCP is an inexpensive, manually driven exploration device designed for pavement assessments with limited subgrade exposure.

• Five field resistivity tests to assess the electrical resistivity of the near surface soils. We will use the 4 point “Wenner” method with electrodes spaced at 5, 10, 20 and 30 feet. The design engineers, to assess cathodic protection and grounding grid requirements, will use this data.

• URS will be doing limited laboratory testing for the project. We anticipate moisture contests, visual manual identification and atterberg limits. All will be done to applicable ASTM standards.

• **Preliminary Recommendations for Spread Footings, Mat Foundations.** - Allowable soil bearing pressure, stated as net or gross pressure at the underside of foundation level. State how allowable pressure changes with depth.
  - Vertical Subgrade Reaction Modulus “k” for slab on grade design.
  - Lateral sliding friction coefficients between soil and concrete.
  - Active and at-rest equivalent fluid pressures for the design of earth retaining structures.
  - Passive equivalent fluid pressures used to resist horizontal forces.
  - Soil unit weights dry and saturated.
  - Backfill material specifications and installation specifications for subgrade and base material, including Preliminary Recommendations for preparation, placement, and compaction. Comment on the use of native materials for backfill material.
  - Settlement values (total and differential, including long term settlements over period of several years for the reciprocating machinery).
  - Minimum depth to bottom of footing based on frost depth and bearing values.
  - Comment on the appropriateness of increased allowable soil bearing and lateral resistance for short duration loads.
  - Anchorage requirements for the shallow foundations.

• **Preliminary Seismic Considerations**
  - Discuss past seismic activity, including known faults, and potential for a future event.
  - Discuss potential for liquefaction during a seismic event.
  - Define the Site Class and Soil Profile per 2006 edition of the IBC.
2 FIELD AND LABORATORY INVESTIGATIONS

2.1 SUBSURFACE INVESTIGATIONS

The field exploration program was conducted between September 18 and September 25, 2007. The subsurface investigation included the completion of twelve test pits to assess near surface soil and rock characteristics, and thirty dynamic cone penetration (DCP) tests along the roadway alignments to evaluate the near surface bearing capacity and moduli of onsite soils.

2.1.1 Test Pits

The test pit exploration program was conducted between September 18 and September 19, 2007. The program consisted of 12 test pits excavated to depths of 7 to 16 feet below ground surface (bgs). Approximate test pit locations are shown on the Figure 2. Test pit logs are presented in Appendix A.
